The treated tissue, following the refrigeration period, is returned to room temperature and placed in a fresh trypsin solution (about 30 ml per kidney) and is stirred magnetically for 2–3 hr. The cell suspension thus obtained is centrifuged for 5 min at 1,000*g*, the supernatant trypsin medium discarded and replaced with calcium-free amphibian Ringer's solution, 1 ml. for each kidney. The suspension usually contains approximately 10^6 cells per ml per kidney Culture dishes are seeded with a final concentration of 500,000 cells per ml of culture medium The culture dishes then are sealed air-tight The composition of the culture medium is nutrient medium NCTC 109, diluted by adding 54 ml of double-distilled water with 100 ml of NCTC 109, 10 ml , calf serum, 2 0 ml , chick embryo extract, 2 0 ml , 5 per cent lactalbumin hydrolysate in amphibian Ringer's solution, 1 0 ml , glutamine (100 m*M*), 0 2 ml , penicillin, about 500 units per ml of medium

Extensive cell sheets form within two to three days when the cultures are kept at 25° C The cultures then are washed and fed with the above culture medium without lactalbumin hydrolysate The monolayer sheets have been maintained, by feeding every three or four days, in good condition for several months Attempts are now being made to derive a cell line from these frog kidney cultures

Successful eye implants have been obtained from the cultured cell sheets which previously had been incubated with a crude extract of frog renal tumour, with resulting growth of the implant in the intraocular region This preliminary evidence suggests that cellular transformations may have taken place, since normal kidney tissue implanted in the eyes of frogs seldom, if ever, exhibits any growth

This investigation was supported in part by a Public Health Service post-doctoral research fellow-

ship, *CF*–12,861, from the National Institutes of Health, U S Public Health Service.

Acylase Activity of Ascites Tumour Cells on Dichloroacetyl Derivatives of Amino-acids

WHILE investigating the specificity of acylase activity of soil bacteria on acyl derivatives of amino-acids[1–3], we noted that the acetone powder of Ehrlich ascites carcinoma cells was able to hydrolyse dichloroacetyl-DL-aspartic acid but not (or only to a small extent) the dichloroacetyl derivatives of some amino-acids such as DL-glutamic acid, DL-serine. DL-methionine and DL-phenylalanine[4]

We have now investigated the acylase activity of lyophilized powder of ascites tumour cells such as Ehrlich ascites carcinoma, sarcoma 180, leukæmia *SN* 36, ascites hepatoma *MH* 134 and *MH* 129P in *C3H* mice, and *AH* 7974, *AH* 130, and Yoshida sarcoma in rats on dichloroacetyl derivatives of the following twelve amino-acids DL-aspartic and DL-glutamic acids, glycine, DL-alanine, DL-valine, DL-leucine, DL-phenylalanine, DL-tryptophan, DL-serine, DL-threonine, DL-methionine, and ε-*N*-benzoyl-DL-lysine

Lyophilized powder of ascites tumour cells was prepared as follows intraperitoneally transplanted ascites tumour cells were aspirated at the fifth day after transplantation, centrifuged at 1,000 r p m for 10 min washed three times with phosphate buffer solution, and then lyophilized It was confirmed that the cells contained almost 85–95 per cent tumour cells

Five mgm of lyophilized powder of ascites tumour cells were added to 1 c c of neutralized 0 1 *M* substrate and 1 c c of *tris* buffer at *p*H 8 2, and the mixture was incubated at 37° C for 2 or 18 hr in the presence of toluene, and then titrated by Grassmann–Heyde's method

The results obtained in the experiments carried out, under comparable conditions, on the acylase activity of lyophilized powder of eight ascites tumours are presented in Table 1 Ehrlich carcinoma, sarcoma 180 and leukæmia *SH* 36 were all able to hydrolyse dichloroacetyl-DL-aspartic acid but not (or only to a small extent) the dichloroacetyl derivatives of the other eleven amino-acids It is of interest that *MH* 134, *MH* 129*P*, *AH* 7974, *AH* 130, and Yoshida sarcoma differed from Ehrlich carcinoma, sarcoma 180, and leukæmia *SN* 36 in failing to hydrolyse dichloroacetyl-DL-aspartic acid Incidentally, *MH* 134, *MH* 129P, *AH* 7974 and *AH* 130 were hepatoma The low acylase activities of *AH* 7974 and *AH* 130 seem worth noting when considered together with the fact that the rat liver could hydrolyse dichloroacetyl-DL-aspartic acid[5]

Thus, our experiment showed that there is a significant difference among ascites tumours in their capability of hydrolysing dichloroacetyl derivatives of amino-acids, and that acylase activity may be available as a tool for studying biochemical specificity of living material[1–3]

We thank Dr S Tatsuoka and Dr T Kaziwara, of Takeda Research Laboratories, for kindly supplying lyophilized powder of ascites tumour cells

BIOLOGY

Chloride Regulation in *Triops*

LITTLE physiological work on the branchiopods has been reported because of their relative scarcity and the unpredictability of supplies of animals Among the freshwater species Krogh[1] reports on some preliminary experiments with *Branchipus* and *Triops* (*Apus*), Panikkar[2] gives some figures for the blood concentration of *Chirocephalus*, and Fritzche[3] gives a blood concentration for *Daphnia*

An opportunity arose for me to use a few specimens of *Triops cancriformis* (Bosc) bred in laboratory conditions by Mr A R Longhurst The level of

The digests consist of 5 mgm of lyophilized sample, 1 c c of neutralized 0 1 *M* substrate, and 1 c c. of *tris* buffer at *p*H 8 2 at 37° C. Hydrolytic activity was measured by Grassmann–Heyde's alcoholic titration method.

blood concentration was measured and some simple experiments were made to determine the degree of osmoregulation which the animals could achieve Whole blood was withdrawn from the large dorsal sinus with soda-glass cannulæ and the chloride concentration of measured volumes determined by a Conway microdiffusion method[4] using Copenhagen sea-water as a standard.

The estimate for blood chloride concentration for six fed animals kept in filtered lake water (4 8 m moles chloride/kgm water) was 42·7 ± 5 4 m moles chloride/kgm water (range, 34 8–48 4) If chloride represents about 80 per cent of the anion concentration, the figure for total concentration would be about 55 m equiv /kgm water. It is clear from this estimate that *Triops* can maintain a blood concentration appreciably higher than the medium, and can be compared with some of the other entomostracan crustaceans in fresh water (Table 1)

Table 1

Animal	Blood conc m equiv /l	Method of estimation
Branchipus (ref 1)	30	Vapour pressure
Chirocephalus (ref 2)	77	Vapour pressure
Daphnia (ref 3)	68	Freezing-point
Triops	55	Chloride

In *Branchipus* and *Chirocephalus*, the ability to maintain this concentration against the osmotic gradient was dependent on salt uptake from the food, since starved animals quickly lost control To test the effects of starvation on osmoregulation, some specimens of *Triops* were put into a large volume of distilled water (40 l) The animals were sampled at intervals and the distilled water changed twice daily for 6 days The blood chloride concentration remained high even after 6 days in distilled water, except for two moulting animals (Fig 1) Within 4 days two other animals had moulted and died After 6 days, one of the two survivors was moulting and the other in a poor condition, although its blood concentration was still high

A further experiment was made in which some specimens were put into a sea-water dilution hyperosmotic (68 m eq /kgm water) to the blood It is clear that these animals have shown a very different reaction to this reversed osmotic gradient (Fig 1) After only 3 hr, the blood concentration rose to equivalence with the medium, and remained at this level for 3 days without any indication of a subsequent control At the end of this time the animals began to lose tone

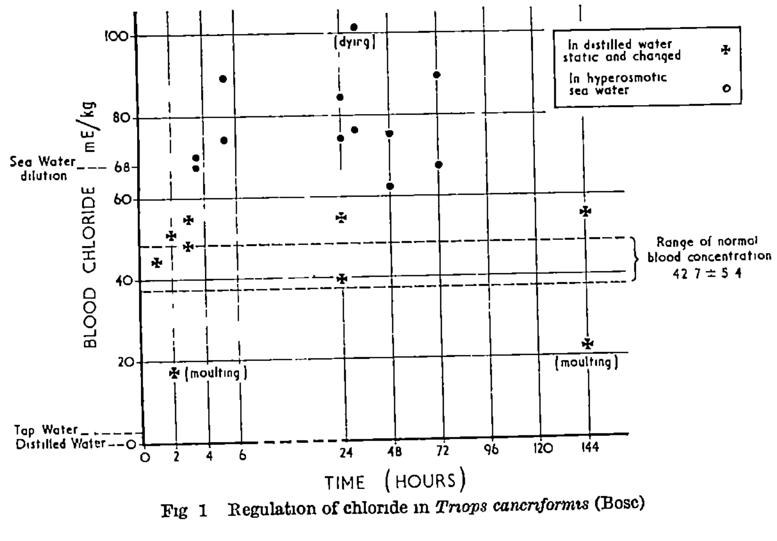

Fig 1 Regulation of chloride in *Triops cancriformis* (Bosc)

It can be concluded that in its normal environment, *Triops* maintains its blood more concentrated than the medium by excluding the osmotic inflow of water, that is. it is relatively impermeable, and that its salt requirements are met by food intake In a slightly hyperosmotic medium, however, it is unable to control either the influx of salt or the osmotic efflux of water

Moulting. and the associated breakdown of cuticle impermeability, seriously impair the mechanism of osmotic control so that animals in this condition quickly succumbed to an osmotic stress

It would be of interest to know more about the physiology of osmoregulation in this species especially in relation to the function of the renal organ This appears to be a large and complex structure, and perhaps one might predict that the animal has an efficient mechanism for salt resorption

Effect of Feeding Griseofulvin on Rate of Growth of Chicks

GRISEOFULVIN, originally isolated from *Penicillium griseofulvum* by Oxford[1] *et al* in 1939, is produced commercially by the fermentation of three *Penicillium* species. *griseofulvum* Dierck X, *janczewskii* and *patulum*. Brian[2] *et al* first described its antifungal properties in 1946, but another twelve years elapsed before Gentles[3] demonstrated its efficacy against *Microsporum canis* and *Trichophyton mentagrophytes* when administered orally to infected guinea pigs

This discovery greatly stimulated interest in the clinical use of griseofulvin and many trials against a variety of dermatophytes have since been carried out[4]

Work on toxicity indicates that large doses injected intravenously in rats cause a transient depression of mitosis while intraperitoneal administration severely damages the seminal epithelium[5], but when taken orally, the toxicity of griseofulvin is low[6,7] In view of the low oral toxicity and in the absence of any published reports on this aspect, it was decided to investigate the influence of griseofulvin in the diet on the rate of growth of chicks

Four groups, each of 26 day-old broiler type cockerels, were used, two groups were fed commercial broiler crumbs, containing 5 mgm procaine penicillin/lb, and the other two received the same basal diet supplemented with 5 mgm griseofulvin/lb On arrival the newly hatched chicks were distributed among the groups according to weight so that the average initial weights were constant, 40 gm in this case. Rearing was carried out in wire-floored tier brooders and the chicks were weighed weekly over a period of four weeks. For the analysis of the results, regression coefficients of logarithm weight on time, based on the two weekly group means for each diet, were calculated and the significance of the difference between the regressions tested by means of a *t*-test in the usual way.

Table 1 AVERAGE WEIGHTS OF CHICKS (GM.)

Diets	Beginning of week					Regression coefficients, diets on weeks
	1	2	3	4	5	
Control + griseofulvin	40·0	86·2	175·7	305·3	467·7	0·2693
Control	40·0	85·3	169·8	291·4	447·9	0·2636
Difference	—	0·9	5·9	13·9	19·8	0·0057
						$t = 2·33$, $P < 0·05$

From the results shown in Table 1 it is apparent that griseofulvin stimulated growth significantly throughout the period of the trial. The amount of food consumed per lb. of live weight was 1·98 lb. for the griseofulvin supplemented group and 1·95 lb. for the control group. The difference between these figures is not significant.

The assistance of I.C.I., Ltd., in providing facilities for this experiment is gratefully acknowledged.

Feeding of Bamboo Flowers to Laboratory Rats and Mice

ACCORDING to a popular myth there is a baffling connexion between the flowering of bamboos and the appearance of rat hordes which spread around destroying crops and eating chickens, puppies and even babies[1]. The present inquiry is an attempt to explain the mysterious phenomenon of an abnormal increase in field rats associated with the flowering of bamboos as recently witnessed in North-east Frontier and Tripura areas. The problem was approached from the point of view of evaluating the palatability, the œstrogenic activity and the reproduction stimulating values of bamboo flowers for rats.

Small quantities of 'mooli' bamboo flowers and fruits and 'pularwa' bamboo flowers from the affected area were received in a semi-dried condition. On dry-matter basis the percentages of crude protein in these samples were 11·39, 14·34 and 13·90 and of crude fibre 39·10, 19·42 and 31·71 respectively compared to the values of 12·81 crude protein and 3·58 crude fibre in the stock diet of rats. The laboratory rats did not relish these substances *per se*, but their inclusion in the normal diet of groups of rats at 10 and 20 per cent levels showed that the total dry matter ingestion may be slightly stimulated at the lower level of incorporation.

An evaluation of the œstrogenic activity in 'mooli' flowers was carried out according to Bickoff *et al.*[2]. Groups of six immature mice each were fed the normal and experimental diets for a period of one week before they were killed for determining the weights of the freshly excised uteri. The results in Table 1 show that the œstrogenic activity in the 'mooli' flowers was practically nil at the levels tested.

Table 1. UTERINE WEIGHT RESPONSE OF IMMATURE MICE ON DIETS CONTAINING THE EXTRACT FROM BAMBOO FLOWERS

Group No.	Addition to 100 gm. normal diet	Live weight (gm.)	Uterine weight (mgm.)	Difference compared to control
I	Nil	5·33 ± 0·61	3·01 ± 0·42	—
II	Stilbœstrol, 0·75 μgm.	5·50 ± 0·62	5·58 ± 0·63	Highly significant
III	Extract from 8 gm. of air-dried bamboo flowers	5·33 ± 0·61	3·20 ± 0·55	—
IV	Extract from 1·6 gm. of air-dried bamboo flowers	5·67 ± 0·76	3·30 ± 0·42	—

Direct evidence of the incorporation of bamboo flowers in the stock diet of rats on their reproductive performance was obtained with local bamboo (*Bambusa arundinaceae*) flowers. Six male and twelve female adult white rats were distributed in three identical groups. One group received the normal diet while the other two groups received diets in which shade-dried bamboo flowers were incorporated at 2 and 15 per cent levels, respectively. The male and female rats of each group were kept separately during the first 15 days of experimental feeding. They were then mated within the groups and continued on the scheduled diets until all the female rats brought forth litters. The average data are recorded in Table 2.

Table 2. OBSERVATIONS ON THE REPRODUCTIVE PERFORMANCE OF RATS ON BAMBOO FLOWER DIETS

Group No.	Level of bamboo flowers in normal diet (per cent)	Period from mating to littering (days)	Litter size	Weight per new-born rat (gm.)
I	Nil	30·00 ± 2·61	8·25 ± 1·44	4·88 ± 0·05
II	2	25·75 ± 1·25	8·00 ± 0·00	5·10 ± 0·11
III	15	36·75 ± 10·02	7·25 ± 0·85	4·80 ± 0·13

The differences between the control and experimental groups were statistically not significant in regard to the length of the period from date of mating to date of littering, litter size or the weight of the new-born rat. Evidently the incorporation of bamboo flowers in the stock diet under the conditions of the test did not have any stimulatory effect on the reproductive activity in rats.

The bamboo flowers were not palatable to rats even in the fresh state. The sugar content in the nectar of bamboo flowers is lower than in those of common honey plants like apple, dandelion and clovers[3]. Bamboo sprouts promote growth of pathogenic bacteria which barely grow on the basal medium[4], and the bamboo seed is superior to both rice and wheat in overall nutritive value[5]. Breeding disturbances in sheep in Australia have been related to the presence of œstrogenic substances in subterranean clover[6], but their high concentration in spring grasses in Great Britain has been without any reproductive disturbance in any species so far[7]. The search for œstrogenic substances in bamboo flowers was prompted by their well-established occurrence in plant materials and their value as growth promoters[8] The possibility that, as growth promoters, œstrogenic substances from diverse sources may have unrecognized useful potentialities may not be discounted

The limited evidence presented here does not support the myth of increase in rat population as a direct result of the ingestion of bamboo flowers

We are grateful to the Director, Indian Veterinary Research Institute, Izatnagar, for his interest in this work

Classification of Fossil Microplankton

It is becoming increasingly desirable that a definite decision be made as to whether the fossil organic-shelled microplankton (dinoflagellates, hystrichospheres, and genera of presumed microplankton *incertae sedis*) should be classed, for nomenclatural purposes, in the animal or in the plant kingdom The dinoflagellates, a group of unicellular organisms some of which contain chlorophyll, are clearly algae, while others contain no chlorophyll and are vagile and predatory, and are at present alternatively regarded as the class Dinoflagellata or class Dinophyceae The hystrichospheres, typically marine in occurrence and defined by their morphology, are regarded as an order *incertae sedis*, the order Hystrichosphaeridia, and have been treated by most authors as animals the majority are now known to be dinoflagellate cysts, while others, less capable of definite attribution, may be zygospores of desmids, eggs of copepods or other planktonic organisms, or even plant spores

Much confusion about nomenclature must inevitably result when these organisms are indifferently classed in two kingdoms and may thus be dealt with under two different taxonomic codes The proposed third kingdom, the Protista, to comprise all unicellular organisms, has not secured general recognition it is highly unlikely that a third system of nomenclature will be set up A choice must thus be made as to which of the existing systems should be followed, and whichever is decided on must be applied consistently if further confusion is to be avoided

We consider that these groups should be classified as plants The dinoflagellates surviving as fossils are relatively thick-shelled forms, often having an armour of distinct plates Investigations of living plankton show that such forms are relatively sessile and contain chlorophyll the vagile, predatory forms have very thin shells and are probably not capable of fossilization. Evitt[1] has demonstrated that a large majority of the hystrichospheres and allied forms *incertae sedis* possess an opening in the shell (a pylome) through which escape can take place after encystment and are quite certainly the abandoned cysts of dinoflagellates, a conclusion suggested also in many genera by similarities in overall morphology. For these forms, use of the Botanical Rules[2] would be greatly advantageous in that there is provision for the creation of form genera and species the confusion that might result from application of the rule of priority, should the identity of a motile dinoflagellate with an encysted form be proved, may thus be avoided No such provision exists in the Zoological Rules, the comparable vehicle of parataxonomy[3] having been rejected by the International Committee in London, 1958

Classification under the Botanical Rules conforms to a large degree with present practice Deflandre, in his work on the fossil dinoflagellates, has classed them as Dinophyceae the Russian authorities, such as Naumova, regarded all hystrichospheres as plants for taxonomic purposes The majority of workers in this field are palynologists for whom the procedure here proposed would be considerably more acceptable

We therefore propose that the fossil microplankton be regarded as subject to the Rules of Botanical Nomenclature, as applied to fossil plants that, within the framework of this classification, fossil dinoflagellates in the motile stage be regarded as genera and species fossil cysts of dinoflagellates as form genera and species and hystrichospheres and other genera *incertae sedis*, for which a relation to the dinoflagellates has not been proved, as genera and species or form genera and species *incertae sedis*

Until a full re-definition of the order Hystrichosphaeridia, on the basis of a more complete knowledge of their affinities, has been undertaken, we do not feel it desirable to alter the present grouping into families of the hystrichospheres For the present, we consider that it would be adequate if these organisms were classed as plants and descriptions of them are formulated on this basis

Alteration of Permeability of *Lactobacillus plantarum* caused by Chlorpromazine

The mechanism for penetration of oxalacetate into *Lactobacillus plantarum* 17–5 is inducible Unless *L. plantarum* is grown for a few hours in a medium which contains either oxalacetate, acetoacetate or α-ketoglutarate, there is poor penetration of oxalacetate into cell suspensions of this organism afterwards prepared Oxalacetate decarboxylase (which is also inducible) can be readily detected manometrically in whole organism suspensions of *L. plantarum* grown with any of the three compounds already mentioned, but can only be detected in disrupted (acetone-dried) organisms if the bacteria had been grown with L-malate, a compound which induces synthesis of oxalacetate decarboxylase but does not induce the mechanism for oxalacetate to penetrate the cell[1]. An agent which increases cellular permeability, at least with respect to oxalacetate, may be detected by increase of oxalacetate decarboxylase activity of undisrupted *L. plantarum* which had been grown in a medium containing L-malate.

For the experiments reported here, *L. plantarum* was grown at 35° C. in a medium composed of yeast extract, glucose, and L-malate (1.0 gm./100 ml. each). Chlorpromazine was added to the growth medium after the organisms began to increase exponentially. The amount of chlorpromazine added varied within the range of 0.5–5.0 mgm./100 ml. final medium. Growth was allowed to continue for 3–6 hr. after addition of chlorpromazine.

Samples of each culture were examined for gross morphological changes and for differences in density of final growth. Cultures which had grown with less than 3.0 mgm. chlorpromazine appeared like the untreated control. There were fewer cells produced in cultures which contained more than 3.0 mgm. chlorpromazine.

Cultures grown either without or with 1.0 mgm. chlorpromazine were collected by centrifugation, washed and assayed for both oxalacetate decarboxylase and malic decarboxylase (malic enzyme) using methods previously described[1,2]. Since malic decarboxylase is also inducible, but can be readily detected in suspensions of undisrupted cells, changes in the activity of this enzyme served as a control that chlorpromazine inclusion in the growth medium did not quantitatively alter enzyme synthesis[2].

Only cell suspensions of bacteria which had been grown with chlorpromazine showed appreciable increase in oxalacetate decarboxylase activity (Table 1). There was no effect on malic decarboxylase activity of cell suspensions or of either oxalacetate decarboxylase or malic decarboxylase activity of acetone-dried cells.

Table 1. EFFECT OF CHLORPROMAZINE (CPZ) DURING GROWTH ON SUBSEQUENT ENZYME ACTIVITY OF *L. plantarum*

It has already been shown that one site of activity of chlorpromazine in *L. plantarum* involves diphosphophyridine nucleotide and is related to the ability of chlorpromazine to serve an electron donor[2,3]. Quite possibly, the alteration in membrane permeability caused by chlorpromazine in the experiments reported here also involves a site dependent on diphosphopyridine nucleotide. In other recent experiments we have shown that chlorpromazine increases membrane permeability of animal-type cells[4], and plant-type cells (Nathan and Zahalsky, in preparation). A preliminary survey of phenothiazines indicates that ability to alter membrane permeability is linked to ease with which free radicals are formed.

Chlorpromazine promises to be a useful tool for making materials in the surrounding milieu accessible to the inside of cells without injuring the cell to the extent that it cannot grow and reproduce.

A Chamber for culturing and collecting the Nematode *Panagrellus redivivus*

Panagrellus redivivus L., Goodey, 1945, is frequently the nematode chosen for laboratory work because of its size (maximum length of approximately 1.5 mm.) and the ease with which it can be cultivated[1]. This free-living worm has been employed for the evaluation of nematocides[2] and repellants[3], in metabolic studies[4], and to induce morphogenesis in predaceous fungi[5].

A constant supply of *P. redivivus* was necessary for work in this laboratory on the activities of fungi that capture and kill nematodes. To meet this requirement a chamber that served for both the culture and collection of *P. redivivus* was designed and employed. The apparatus (see Fig. 1) consisted of a funnel (15 cm. diameter, 60° angle) with a ground lip and attached standard-taper stopcock. A saddle (*A*) constructed of glass rod was placed in the funnel as support for a heavy Petri dish bottom (*B*) and approximately 25 gm. of oatmeal and 45 ml. of water

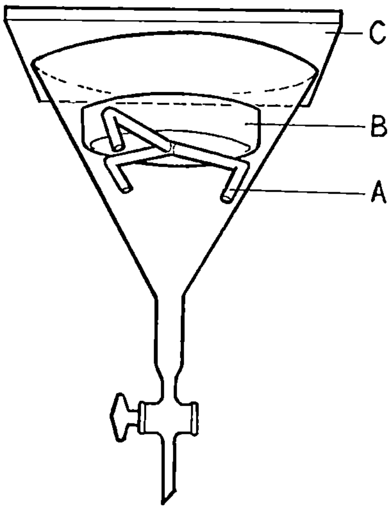

Fig. 1. Chamber for the culture and collecting of *P. redivivus*

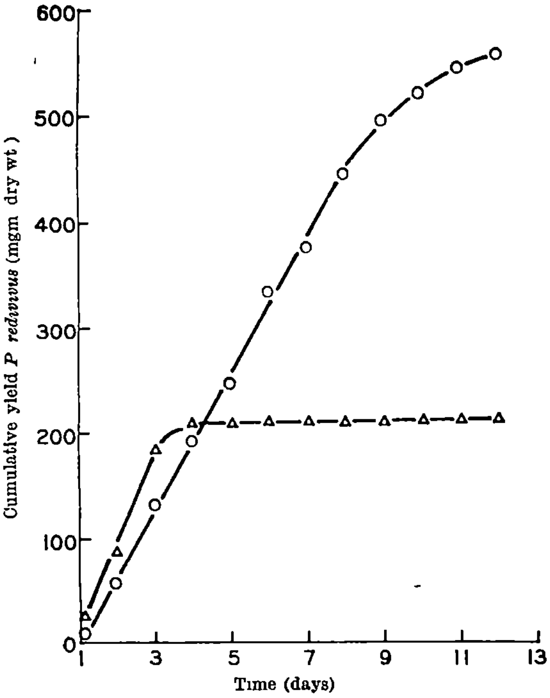

Fig 2 Influence of temperature on the yield of *P redivivus* O, 20° C , Δ, 28° C

were added to the dish (2 × 9 cm) The stopcock was closed and water was then added to the funnel until the liquid-level was 3–4 mm below the open end of the dish The moist oatmeal was inoculated with *P. redivivus* and the unit was closed using a ground-glass plate (*C*) as lid The dish was arranged in a manner such that it did not touch the wall of the funnel and was approximately 1 0 cm below the lid.

P. redivivus multiplied rapidly and after 3–5 days at 28° C or 7–8 days at 20° C numerous adults and larvæ moved out of the oatmeal, over the edge of the dish and into the water contained in the funnel. Since the density of nematodes exceeds that of water, the worms were concentrated above the stopcock by sedimentation The dry weight of nematode tissue yielded by chambers incubated at 20° and 28° C. was determined at daily intervals from the time of first harvest The results, illustrated in Fig 2, showed that 20° C. was the more suitable storage temperature Although development of *P. redivivus* was more rapid at 28° C , worm production at that temperature ceased after 4 days At 20° C nematodes were produced for 12 days and the total yield exceeded 550 mgm. Since a dry weight of 1 0 mgm. was equivalent to approximately 30,000 individuals, more than 16×10^6 worms were collected in 12 days from each chamber incubated at 20° C No attempt was made to collect or enumerate the many nematodes that remained in the oatmeal, but on prolonged incubation their numbers were depleted by sporadic migrations from the dish into the funnel

The chamber as described is efficient and convenient and serves simultaneously for the culture and collection of *P. redivivus* However, it can be sterilized or modified to meet specific requirements. The stem of the funnel can be refrigerated to maintain worms in a state of relative inactivity until collected Moreover, the stem can be elongated and filled with glass beads. Worms collected after entering the funnel and working their way down the bead column to the stopcock are relatively free of contaminating micro-organisms.

We thank J Postman and the New Brunswick Scientific Co (New Brunswick, New Jersey) for construction of the chambers This investigation was supported in part by National Science Foundation grants *G*5949 and *G*9749

Periodic Acid–Schiff Technique for the Demonstration of Extra- and Intra-cellular Stages of Gregarine and Coccidian Protozoa

DURING a histological investigation of gut structure in the rhynchocœlan *Lineus ruber*[1] it was noted that both extra- and intra-cellular stages of the gregarine *Urospora nemertes*, which infected approximately 75 per cent of the specimens examined, stained intensely with the periodic acid–Schiff technique[2]. The intra-cellular stages, in particular, are difficult to demonstrate by routine staining methods, but after periodic acid–Schiff treatment they are strikingly prominent and may be readily located in sections with the low-power objective

In view of the potential value to the protozoologist of this use of the periodic acid–Schiff technique its effectiveness with other gregarine species and the related group of parasitic protozoa, the Coccidia, was investigated In all cases every stage in the life-history gave a strong positive reaction and the four species of coccidians examined (*Eimeria tenella*, *E maxima*, *E acervulina* and *E. necatrex*, from the gut of the domestic fowl) were readily located even when only small numbers were present in the infected tissue. Particularly striking results were obtained with the gametocyte stage (Fig 1)

The choice of fixative does not appear to influence the reaction to periodic acid–Schiff to any significant extent and comparable results were obtained after

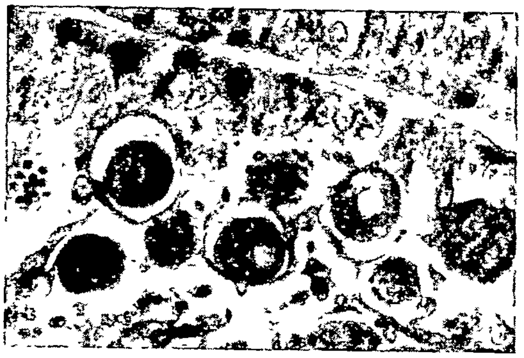

Fig 1 Transverse section of fowl cæcum showing macro- and micro-gametocytes of *Eimeria maxima* Trichrome periodic acid–Schiff (× 650)

fixation in Susa, 5 or 10 per cent neutral formalin or 90 per cent alcohol If details of host tissue are required, the periodic acid–Schiff may be followed by the celestin blue/hæmalum and orange *G* method[2] to give a full trichrome stain

I wish to thank Dr. Horton-Smith, Houghton Poultry Research Station, Houghton, Huntingdonshire, for supplying material infected with the four species of *Eimeria*

ENTOMOLOGY

Evaluation of the Activity of Some Diphenyl Compounds on Winter Eggs of the Fruit Tree Red Spider

For several years some red spider ovicides have appeared on the market Most of these compounds are active chiefly on the summer eggs, and far less active on the winter eggs of the fruit tree red spider *Metatetranychus ulmi* Koch. One of these compounds, 2,4,5,4′-tetrachlorodiphenyl sulphone (tetradifon), shows extremely high ovicidal and larvicidal activity on Tetranychids, but is not active on the winter eggs of *Metatetranychus ulmi* In the course of investigation of the past five years a large number of diphenyl compounds has been tested on tetranychids[1] Some of them have been examined for activity on the winter eggs and compared with some other compounds The latter experiments are reported here

Apple twigs bearing winter eggs of the fruit tree red spider were collected during winter and kept outdoors Before treatment the twigs were cut into pieces of about 4 in and then dipped into miscible oil–water emulsions The treated pieces were put into water-filled vials The whole was kept in climatically conditioned racks under continuous illumination at 20–22° C and 80–90 per cent relative humidity

A serious difficulty of these laboratory experiments is the high percentage of untreated eggs that do not hatch This percentage may vary between 30 and 80 after one month of incubation Hatching is especially reduced if heavily infested twigs are used, probably as a result of overpopulation Nevertheless, the differences between the various substances seem justified by their consistency under various levels of hatching in the batches

The reduction of hatching shown in the tables refers to the percentages calculated after Abbott's formula Table 1 shows the results of trials with tetrachlorodiphenyl compounds as compared with the known acaricides CPBS and 'Chlorbenside' Tetrachlorodiphenyl sulphone is not active at all, whereas the sulphide homologue is highly active The latter appears to be the best of the compounds examined

Table 2 summarizes the results obtained with the trichloro-diphenyl compounds and tetrachlorodiphenyl sulphide.

Table 1 Reduction of Hatching of Winter Eggs of *Metatetranychus ulmi* Koch after dipping of Egg-bearing Apple Twigs in Emulsions Mean Percentages of Three Experiments in 1957 and 1958

Compound	Concentration (p p m)	Percentage reduction
 (*V* 18)	500 250 125	7 10 5
 * (*V* 110)	500 250 125	7 14 0
 (V 101)	500 250 125	100 90 87
 (CPBS)	500 250 125	71 61 29
 * ('Chlorbenside')	500 250 125	64 66 79

* One experiment

Table 2 Reduction of Hatching of Winter Eggs of *Metatetranychus ulmi* Koch after dipping of Egg-bearing Apple Twigs in Emulsions Mean Percentages of Three Experiments (1959)

Compound	Concentration (p p m)	Percentage reduction
 (*V* 17)	1,000 300 100	0 0 0
 (*V* 114)	1,000 300 100	92 0 0
 (*V* 113)	1,000 300 100	98 61 0
V 101	300 100 30	100 98 97
50/50 mixture *V* 18/*V* 101	150/150 50/50 15/15	99 92 56

In a previous paper[2] it was shown that *V* 18, *V* 110 and *V* 101 were equally effective on eggs and larvæ of *Tetranychus urticae* Koch on bean plants When dipping eggs of *Tetranychus urticae* Koch in emulsions of these compounds, however, *V* 18 shows the highest ovicidal activity After hatching of the surviving eggs, the larvæ are killed by the deposit of all three compounds, so that the overall mortality is the same But if leaves bearing eggs of *Tetranychus* at the under side are treated on the upper side only, the highest egg-kill is obtained by *V* 101, and the least kill by *V* 18, whereas *V* 110 takes an intermediate position This result is evidently a consequence of the different penetration properties of the compounds

In this respect it is interesting that the highest activity on winter eggs of *Metatetranychus* is shown by *V* 101, which also has the best leaf-penetration In laboratory trials *V* 101 appears also more active than CPBS, which has been in use for the control of winter eggs of the fruit tree red spider for some years The addition of *V* 18 does not seem to influence the action of *V* 101

The same sequence of activity on the winter eggs is seen with the trichloro-compounds *V* 17, *V* 114 and *V* 113 (Table 2) Also in this case the sulphide homologue is more active than the sulphone, presumably as a result of the better penetration through the egg shell The activity, however, is far less than with *V* 101

A Technique for exposing Individual Flies on Insecticidal Deposits

A NUMBER of methods have been described for testing residual insecticides against various insects, and for the bio-assay of insecticide deposits on treated surfaces In general these entail confining the insects for testing under a transparent container on the treated surface for a certain time of exposure, and measuring the mortality after holding in clean cages for a further period Wiesmann[1] used halves of Petri dishes, while Hadaway and Barlow[2] used glass tubes, inverted funnels and 'Perspex' cylinders

One of the difficulties common to these methods, particularly when testing flying insects, has been to ensure that the insect remains in contact with the treated surface for the whole of the time of exposure According to the type of apparatus, one is advised to blow down the cylinder, or to rotate the tube in order to induce the insect to settle on the insecticide deposit

The method described below was evolved for the bioassay of treated leaf surfaces, using *Stomoxys calcitrans* as the test insect It has the advantages that the flies do not have to be anæsthetized or handled, and are forced to walk on the treated surface throughout the period of exposure, irrespective of the duration of this period

The apparatus used is shown in Fig 1 It consists of two squares of 'Perspex' (*A* and *B*) measuring 2 × 2 × 3/16 in, each having a central circular hole 1 in in diameter The two squares are held together by thin strips of 'Perspex' cemented along opposite edges, but leaving a space to allow a thin 'Perspex' shutter (*C*), 3 × 2 in, to slide between the squares At one end of the shutter is a hole 1 in in diameter, so that in one position of the shutter the holes in the three pieces of 'Perspex' are concentric A 3 × 1-in glass cylinder (*D*) is cemented into the hole in the 'Perspex' square (*A*)

A 3/16 in 'Perspex' disk (*E*) cemented to the end of a 4-in glass rod (*F*) slides smoothly inside the cylinder, through a cork-guide (*G*) The glass rod is fitted with an adjustable rubber ring (*H*) which determines the downward travel of the 'Perspex' disk

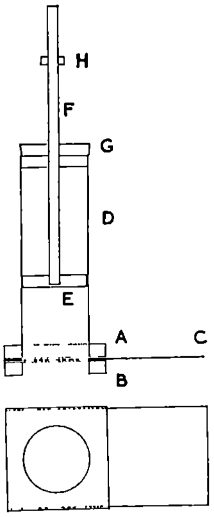

Fig 1

To use the apparatus, individual flies in 3 × 1-in. tubes are used A 3 × 1-in tube containing a single fly is fitted into the hole in 'Perspex' square *B* The tube containing the fly is darkened by holding in the hand, and the shutter opened, to allow the fly to pass into the apparatus, and the shutter again closed. This operation is performed with the circular disk (*E*) in the fully raised position

The apparatus is placed on the surface to be treated, the shutter opened to allow access to the treated surface, and the disk depressed to a pre-set position depending on the height of the test insect. Care must be taken to ensure that the fly is in a walking position on the treated surface In this final position it is impossible for the fly to turn over or walk on the wall of the cylinder

At the end of the period of exposure, the disk is raised to allow the fly to move off the treated surface, and the shutter then closed The fly can now easily be transferred to a holding cage

Other advantages of this method are (1) With practice, exposures can be performed very quickly, for example, with *Stomoxys calcitrans* it is in the order of the exposure period plus 15 sec (2) The smooth undersurface of the 'Perspex' disk causes no damage to the dorsal surface of the insect (3) The apparatus can be dismantled and cleaned by rinsing and swabbing with alcohol Acetone, benzene and similar solvents cannot be used as they cause crazing of the 'Perspex', and loosening of the cemented joints This disadvantage would be overcome if the apparatus were made entirely of glass (4) The apparatus can be made easily and cheaply in any laboratory (During the preparation of this communication for publication, it was learnt that a similar apparatus had been described by Kernaghan of Northern Nigeria, at a recent meeting of the International Scientific Committee for Trypanosomiasis Research at Jos)

GENETICS

Primary Embryonal Sex Ratio in Normal Pregnancies determined by the Nuclear Chromatin

MANY attempts have been made to establish a sex ratio for embryos of a younger gestational age Unfortunately, external genitals are an unreliable index for this purpose before the 5-cm stage Former investigations were based on histological examination of gonadal tissue[1] Recently, Tricomi *et al* [2] determined the ratio of male to female embryos by examining the placental tissue obtained by curettage for the treatment of incomplete abortions Their investigation was based on the observations of Graham[3] and Glenister[4], who noted the presence of the sex-chromatin in the trophoblastic cells before gonadal differentiation Park[5] was able to demonstrate that a morphological sex difference is present in the trophoblastic cells of 10–12-day-old embryos

The accepted secondary sex ratio of man the world over is 106 males to 100 females All data available now indicate that more males than females are lost during the early months of pregnancy Tricomi *et al* [2] examined 242 abortion specimens and found a ratio of 160 100

The primary sex ratio, that is the ratio which prevails at the time of fertilization, is not yet known The investigators mentioned accept an incidence of abortions of 10 per cent and by using a weighted mean they assume that the primary sex ratio may approximate 111 100, male to female

Since all investigations until now were carried out on placental tissue obtained from curette material of incomplete abortions, it seemed to us worth while to examine the distribution of sexes in normal early pregnancies

Fresh placental tissue obtained from 300 medical abortions in apparently normal early pregnancy was investigated Identification of the sex-chromatin mass was carried out according to the usual histological method. One hundred cells from each specimen were examined at an approximate magnification of 1,000 (oil immersion) The percentage of the sex-chromatin positive cells for female tissue ranged from 30 to 80, that for male from 1 to 8 Preliminary investigations established the reliability of the procedure[6]

165 of our specimens have been classified as male and 135 as female This result gives a ratio of 122 100, male to female Though the material is too small a series to be conclusive, the results of our investigations indicate a greater incidence of the male sex in the primary ratio than that calculated by Tricomi *et al* [2]

Since theoretically there should be as many Y-bearing as X-bearing sperm, the ratio at the time of conception should be 100 100 Why an egg should be fertilized more frequently by a sperm with Y-chromosome would then have to be explained

A Rare Phenotype within the *Gm* System

IN 1956 Grubb[1] published the discovery of a serologically demonstrable γ-globulin factor, which was found to be inherited as a Mendelian dominant Since then several related factors apparently belonging to a common hereditary system, the *Gm* system, have been demonstrated At present the system comprises the following factors· $Gm(a)$ (ref 1), $Gm(x)$ (ref 2), $Gm(b)$ (refs 3,4) and *Gm*-like (ref 5)

Disregarding *Gm*-like, which has not been found in Caucasians, the following phenotypes have been reported $Gm(a+x+b+)$, $Gm(a+x-b+)$, $Gm(a+x+b-)$, $Gm(a+x-b-)$ and $Gm(a-x-b+)$ The phenotypes $Gm(a-x+b+)$, $Gm(a-x+b-)$ and $Gm(a-x-b-)$ have not been encountered in spite of rather extensive investigations

According to the study material factors $Gm(a)$ and $Gm(b)$ appear to be Mendelian dominants, being controlled by allelic genes $Gm(x)$ also behaves as a Mendelian dominant, but until now has only been demonstrated in sera exhibiting the $Gm(a)$ factor also In work involving $Gm(a)$ and $Gm(x)$ typing in adults from a series of Danish paternity cases one example of the phenotype $Gm(a-x+)$ was encountered The serum sample belonged to a healthy woman, A P , and the result was checked by examining a new blood sample at a later date The distribution of *Gm*-phenotypes in the series is shown in Table 1

In order to clarify the significance of the unusual phenotype an investigation of the kindred of A P was undertaken The result of the *Gm* typing is shown in the pedigree (Fig 1)

It is seen that the quite common phenotypes in the P-generation give rise to the rare phenotype

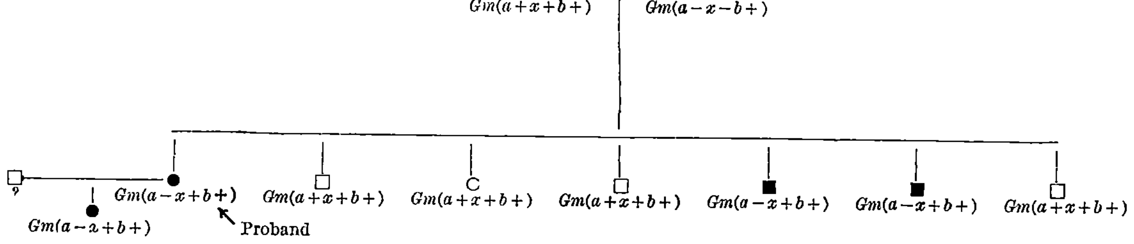

Fig 1

Table 1

Phenotype	No	Percentage
$Gm(a+x+)$	201	24 2
$Gm(a+x-)$	272	32 7
$Gm(a-x-)$	358	43 0
$Gm(a-x+)$	1	0 1
Total	832	100 0

$Gm(a - x + b +)$ in 3 out of 7 sibs in the F_1 generation and in the serum of the single representative of the F_2 generation This may well be explained by the assumption of a rare gene—or closely linked gene combination—*bx*, beside the frequent gene *ax*, the genotype of the father of the proband being *ax*/*bx*

Our thanks are due to Dr M Harboe, Rikshospitalet, Oslo, who checked the results of our *Gm* typing

Glucose-6-Phosphate Dehydrogenase Activity in Papuans

During a recent investigation into hæmolytic and other anæmias in Papuans the glucose-6-phosphate dehydrogenase (G-6-P D) activity of erythrocytes was estimated in 45 cases Blood was collected into heparin, and on several occasions into acid–citrate dextrose solution, and dispatched by air to Melbourne, arriving the same day The G-6-P D activity was estimated in the Biochemistry Department of the Peter MacCallum Clinic, Melbourne, by the method described by Hsia[1] By this method normal readings are 150–210 units/100 ml The enzyme appears to be relatively stable for at least a week, provided the cells remain intact The highest values were obtained in cases of thalassæmia major, acute hæmolytic anæmia of undetermined cause, and congenital hæmolytic anæmia of unknown cause There was no significant difference in the results obtained, whether A C D solution or heparin was used as an anti-coagulant The twelve subjects used as controls all gave readings within the accepted range of normality

Three examples of deficient activity were found The first was a Papuan adult male, who denied any possibility of racial admixture and appeared to be a typical Papuan from the Rigo district, a few miles from Port Moresby He was suffering from an attack of hæmolytic anæmia of undetermined cause when first seen on June 12, 1960 Electrophoresis of the hæmoglobin showed no abnormality and the alkaline-resistant hæmoglobin test and the direct Coombs test were both negative No G-6-P D activity was found at this time This result was not due to inhibitors, because the addition of blood from a case of thalassæmia major (518 units/100 ml) gave the expected values About two months later 8 units/100 ml of enzyme activity were found and in a further six months the result was 11 units/100 ml Although the patient was given 30 mgm of 'Primaquine' daily for 10 days no evidence of hæmolysis was obtained He stated that his brother had died one year previously from an attack of what seemed to be hæmolytic anæmia He denied that either of them had eaten beans or taken any drug apart from 'Camoquin' at any time

The two other patients with low values of G-6-P D were children One was suffering from thalassæmia major, for which his spleen had been removed His G-6-P D values on three occasions were 56, 46 and 36 units/100 ml The other child was suffering from anæmia apparently due to tuberculosis infection and the G-6-P D value was found to be 66 units/100 ml It has not been possible to confirm this result

It is probable that anæmia which is determined by genetical factors is not nearly as common in New Guinea as is anæmia due to parasitic and nutritional factors However, the finding of thalassæmia[2] and deficiency in G-6-P D in the Territory suggests that further attention should be given to investigating genetical factors

VIROLOGY

Cyclic Events in the Viral Cycle

The polio virus is able to develop only within given limits of temperature The simplest reason for this seems to be that low and high temperatures block viral development by altering the metabolism of the host cell Yet mutants of the polio virus can be obtained which thrive at these low or high temperatures at which the original type is unable to multiply the sensitivity of viral development to temperature is thus controlled by the genetic constitution of the virus Moreover, it was discovered that one mutational event shifts the whole curve expressing the sensitivity of viral development to temperature towards the left or the right psychrosensitivity decreases when thermosensitivity increases and vice versa[1]

The polio virus is able to develop normally if submitted to supra-optimal temperatures during the first part of the cycle only or to infra-optimal temperatures during the second part only Infra-optimal temperatures, which do not block the second part, interfere with the primary phase whereas supra-optimal temperatures, which do not block the first part, interfere with the secondary phase The polio virus is in fact, able to complete its development at high and low temperatures both incompatible with viral multiplication, provided they alternate in the right sequence during one growth-cycle

The effects of infra-optimal temperatures are increased by heavy water, the effects of supra-optimal temperatures decreased In the presence of heavy water the whole curve expressing the sensitivity of viral development to temperature is shifted heavy water decreases the apparent temperature[2]

The fact that a single mutation modifies at the same time in opposite directions the psychro- and the thermo-sensitivity and affects the events taking place during the early phase as well as during the late one, leads to the hypothesis that both phases are controlled by one viral molecule Things happen as if this molecule would undergo reversible structural alterations, the equilibrium of the reaction being shifted by temperature changes

$$A \underset{\text{Supra-optimal temperatures}}{\overset{\text{Infra-optimal temperatures heavy water}}{\rightleftharpoons}} B$$

The state A would allow the completion of the primary phase only, the state B the completion of the secondary phase only Infra-optimal temperatures, by shifting the probability of the molecular structure towards B, prevent the completion of the early phase Supra-optimal temperatures, by shifting the probability of the molecular state towards A, prevent the completion of the secondary phase The effect of deuteration shows that hydrogen bonds are involved in the reaction $A \rightleftharpoons B$

The optimal temperature for viral development probably corresponds to the transition temperature of the reaction at which both states of the alleged viral molecule are equally represented Infra- and supra-optimal temperatures decrease or block viral development by shifting the equilibrium, thus favouring one of the states at the expense of the other The completion of the viral cycle would thus imply a reversible cyclic alteration of a metastable molecule[3]

During the life-cycle of a cell a certain number of molecules, or molecular complexes such as mitotic fibres, genes, chromosomes, undergo reversible alterations of structure On the other hand, vegetative functions, that is, the activity and the biosynthesis of enzymes, are regulated by feed-back mechanisms depending in the last analysis on structural molecular changes It is felt that reproductive and 'cyclic' functions must also be under the control of some feed-back regulating mechanisms Metastable molecules able to undergo reversible structural alterations could be responsible for these mechanisms[4]

Multiplication of Mouse-adapted Influenza Virus in Mouse Lungs after Infection with Very Low Doses

WE studied the dynamics of the infection with influenza virus in mice after intra-nasal administration of extremely low doses White mice were infected with the mouse-adapted Em_2 strain of the $A1$ type influenza virus The virus, used in the form of infected allantoic fluid, showed LD_{50} titres of $10^{5\ 1}$ and $10^{5\ 45}$ 0 1 ml , respectively, as estimated by intra-nasal inoculation of white mice, and a $TCID_{50}$ titre of $10^{4\ 88}$ and $10^{5\ 52}$ 0 1 ml , respectively, as determined in suspended chlorio-allantoic membrane tissue cultures[1]—herein designated as Horváth's *TC* Mice weighing 16–18 gm were inoculated under light ether anæsthesia intra-nasally in individual experiments (altogether 6 experiments in 3 independent series) with 0 05 ml of infected allantoic fluid, containing $10^{-2\ 12}$–$10^{0\ 88}$ $TCID_{50}$ 0 1 ml , in other words, in each case with a lower dose than 1 mouse LD_{50} Starting with the first day after inoculation, 3 mice were killed daily and from their lungs 10 per cent suspensions in Horváth's[1] nutrient medium were prepared. The suspensions were clarified by centrifugation at 2,500 r p m for 10 min and serial 10-fold dilutions of them inoculated into Horváth's *TC* The cultures were incubated at 35° C for 72 hr and the reproduced virus detected by hæmagglutination test on plastic plates[2] The results are shown in Fig 1 It can be seen that the multiplication of the virus in the lungs depends on the dose of the virus administered and shows a cyclic character After administration of the lowest dose (0 0038 $TCID_{50}$ in 0 05 ml), virus was first detected three days after infection It is still present on the fourth day, but thereafter disappears and is not detectable up to day 12 After administration of a 10-times higher dose the virus appears in the lung also on day 3, it is not detectable for the next five days and appears repeatedly on day 9 or 10 after infection The higher the dose administered, the shorter the time intervals

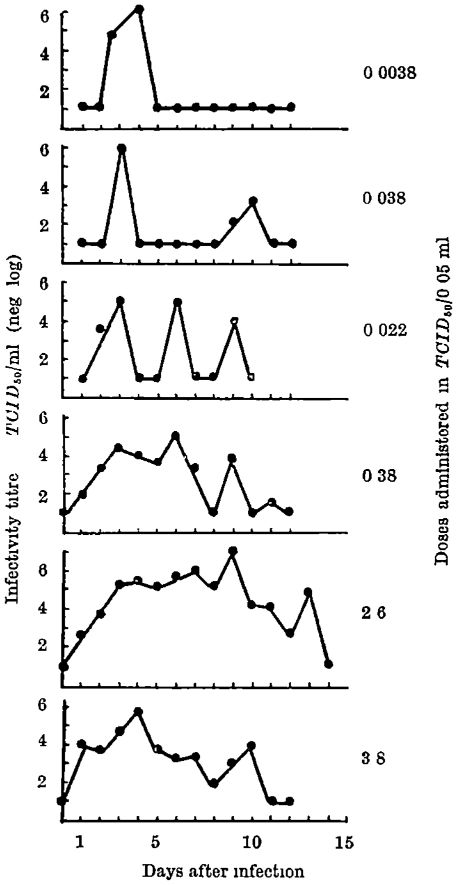

Fig 1

of the cyclic appearance and disappearance of virus in the lungs. After infection with 2·6 $TCID_{50}$ and 3·8 $TCID_{50}$ in 0·05 ml., respectively, a complete disappearance of virus from lungs was not detected during the whole observation period, although even in these cases an appreciable variation in infectivity titres was seen. It is to be noted that the first disappearance of virus and/or a marked lowering of its titre occurred in all experiments 4–5 days after infection. Virus-neutralizing antibodies were not detected in sera of mice for 10–14 days after infection.

We supposed that the disappearance or the marked drop in the infectivity titre of the virus in mouse lungs was due to an interferon-like substance, formed as a consequence of the virus infection. Therefore, 0·1 ml. of undiluted suspensions, in which no virus could be detected, were inoculated into Horváth's *TC* and incubated at 35° C for 24 hr. Thereafter the cultures were treated with a heterologous influenza virus (*A*, *PR*8). We found that after 72 hr incubation the infectivity titre of the added virus was lowered—in comparison with controls—by 90 per cent. Virus-containing lung suspensions were tested for the presence of an interferon-like substance. The suspensions were kept at 4° C for six weeks. During storage the virus was inactivated, for no virus reproduction could be detected after inoculation of such suspensions into Horváth's *TC*. Then Horváth's *TC* was inoculated with these suspensions and treated with homologous (Em_2) and heterologous (*PR*8) virus, respectively, in the same way as mentioned above. In these cases also 90–100 per cent decrease in infectivity titres—in comparison with the controls—were observed. Lung suspensions of non-infected mice, to which Em_2 virus was added *in vitro* and stored also for six weeks at 4° C., did not inhibit the reproduction of the added virus at all. It must be noted that also in these control lung suspensions the virus was inactivated completely during storage. We designate the substance formed in mouse lungs on infection with influenza virus and inhibiting the multiplication of added virus as an 'interferon-like substance', although it is very probable that the interference phenomenon observed in our experiments was caused by Isaacs's[3] interferon, taking into account the results published by Isaacs and Hitchcock[4].

The observed cyclic reproduction of influenza virus in mouse lungs is in agreement with Wagner's[5] hypothesis concerning the interaction of virus and interferon in permanently infected tissues. We suggest that when non-lethal doses are used on mice, the interferon produced prevents the aggressive spread of infection by occupying most of the susceptible cells in the vicinity of the primary focus of the infection. The possibility of a similar interaction of virus and interferon should be assumed after infection of human beings with influenza virus. Interferon could prevent, in some cases, the manifestation of the infection until specific antibodies are formed.

AGRICULTURE

Nitrogen-fixing Blue-Green Algæ in Australian Rice Soils

A FEATURE of myxophycean algæ is the capacity of certain members of the class to fix elemental nitrogen. Blue-green algæ are widely distributed in Nature. They are known to be particularly abundant in regions devoted to the cultivation of rice where the activities of nitrogen-fixing species probably make significant contributions to the maintenance of soil fertility[1,2]. Australia offers excellent opportunities for research. Previously, these have not been exploited even though 46,000 acres are sown to rice annually in the temperate Murrumbidgee Irrigation Area and extensive tracts of country are being developed for rice production in tropical Northern Australia.

As a first step, I have undertaken a survey to determine the distribution of nitrogen-fixing blue-green algæ in the rice areas of Australia and to build up a culture collection for use in laboratory work.

During a visit to Darwin in February 1960, a number of samples was collected from the developing commercial rice crop at Humpty Doo, from the experimental plots of the Commonwealth Scientific and Industrial Research Organization in the same area, and from the two Northern Territory Administration experimental rice stations at Beatrice Hill and Marrakai. Humpty Doo and Beatrice Hill are on the heavy alluvial clays of the Adelaide River and Marrakai is on the somewhat lighter soils of the 'bull dust' plains[3].

The samples were collected in sterile bottles in various situations including supply ditches, at the water surface in the rice crops, from the rice plants and from the submerged soil surface. Every effort was made to ensure that the material was representative of the areas surveyed. No more than five days elapsed between collection of the samples and their return to the University of Sydney.

It is of interest to note that, while blue-green algæ apparently capable of nitrogen-fixation were isolated from almost every sample, their presence in the field was not always obvious. Although typically gelatinous colonies of *Nostoc* were found sometimes to be abundant in the rice fields, they were not common. At present, no simple explanation can be offered for their uneven distribution. In general, algal development was most marked where the movement of the irrigation water was reduced to a minimum and its turbidity was low. Nitrogen-fixing species were not found in the experimental plots possibly because the level of soil nitrogen had been raised considerably by fertilizer applications.

Uni-algal cultures were obtained by routine culture techniques using a range of media both in the liquid form and solidified with agar. Those capable of continued growth on a nitrogen-deficient medium were retained. The composition of this medium, a Winogradsky nutrient solution modified by Acierto (personal communication) and known as No. 5, is KH_2PO_4, 0·25 gm., $MgSO_4.7H_2O$, 0·125 gm., $NaCl$, 0·125 gm., $FeSO_4.7H_2O$, 2·5 mgm., $MnSO_4.4H_2O$, 2·5 mgm., $NaMoO_4.2H_2O$, 0·25 mgm., $CaCO_3$, 5·5 gm.; double glass-distilled water, 1 l., pH 7·2–7·4.

The Northern Territory collection comprises some 36 cultures, none of which has been identified fully

Only two genera are represented, *Nostoc* and *Anabaena*, although one isolate may be a species of *Cylindrospermum* Four isolates have been obtained in a bacteria-free state In December 1960, a survey was conducted in the Murrumbidgee Irrigation Area of New South Wales The samples collected are being treated in the same manner as those from the Northern Territory Already one culture, a species of *Anabaena*, has been obtained free of contaminants

Algæ with probable nitrogen-fixing capacities were found to be a minor element of the algal flora under these conditions However, species of *Anabaena* were almost ubiquitous *Nostoc* was not widespread and representatives of other genera, reported to be nitrogen-fixing, were not found It should be noted that heavy dressings of ammonium sulphate are applied to the soils and that copper sulphate is introduced commonly into the irrigation water in concentrations up to 5 p p m This practice has been adopted, in fact, to control the growth of algal 'scum', largely *Spirogyra*, *Lyngbya* and *Phormidium*, which interferes significantly with the early growth of the rice seedlings

Gelatinous colonies, closely resembling those of a *Nostoc* found in the Northern Territory, were found only occasionally floating in supply ditches and in the rice fields Subsequent examination has shown these algæ to be a species of *Gloeotrichia* It will be of interest to determine whether this organism is capable of nitrogen fixation The Kimberley region of Western Australia, where rice is also being grown, has not yet been surveyed However, several soil samples from that area have been examined It is not regarded as significant that nitrogen-fixing algæ could not be found in this material Attempts are at present being made here to study some of the factors affecting the growth and fixation of nitrogen by several of the bacteria-free isolates in the collection

Financial support for this work is being provided by a research grant from the University of Sydney During the survey, assistance was given by the personnel and officers of both private and government bodies I am grateful to them

Control of the Army Worm on Grazing in Kenya

Infestations of *Laphygma exempta* Wlk (Lep - Noctuidae) on natural grazing present a problem in control because conventional tractor or aerial spraying is uneconomical, and aerial drift spraying is impractical on many farms due to their small area and irregular shape, and to the localization of cleared paddocks between strips of uncleared vegetation Such infestations have therefore been considered uncontrollable and have been left to complete their cycle with a consequent severe loss of grazing The development of the exhaust sprayer for the control of *Schistocerca gregaria* (Forsk)[1,2] offered a cheap and speedy method of control and six tests with this appliance were performed by us on an outbreak in 1959

The sprayer was mounted on a four-wheel-drive vehicle fitted with a governor control which enabled it to be driven at a speed of 5 m p h , and to give an emission-rate of 3–4 gall of spray material a mile The spray nozzle was mounted 6 ft above the ground and the spray plume was emitted vertically upwards so that, with the vehicle travelling across wind, a drift of 100–150 yd was obtained in quite light breezes A standard formulation containing 20 per cent dieldrin in heavy oil was used in the first test, but thereafter crude formulations of DDT in light oil mixed 1 1 with engine oil were used in order to reduce toxicity hazards to operators and to stock

The results of the tests are summarized in Table 1 together with data on air movement and vegetation. Assessments have been recorded visually because this was the only method used in tests 1 and 2, while in 4 a post spraying count was obviously unnecessary, and in 5 and 6 reductions of a fairly high order had occurred on the controls In test 3, a pre-spraying count gave an estimate of four larvæ/ft ^{2} while 72 hr after spraying the estimated populations (based on sixty samples of one foot square from each plot in an area between 7 and 40 yd downwind of the spray track) were

Treatment	Larvæ/ft ^{2}
Control	3 78 ± 0 58
Single application	1 37 ± 0 20
Double application	0 87 ± 0 20

The post spraying counts were intentionally biased on the treated plots, samples being taken in the thickest grass cover where initially more larvæ would have congregated, but even ignoring this bias, the reduction is very satisfactory

The failure in test 4 may be attributed to a combination of factors The very slight air movement was

Table 1

No	Insecticide (per cent)	Wind	Vegetation	Result after 72 hr	
				Sprayed area	Control
1	Dieldrin 20	Light	Grass, occasional trees	Heavy reduction	Slight reduction
2	DDT 12 5	*c* 5 m p h	Good grass cover, no bushes	Heavy reduction	No change
3	DDT 12 5 DDT 12 5 × 2*	*c* 5 m p h *c* 5 m p h	Good grass cover, no bushes Good grass cover, no bushes	Heavy reduction Very heavy reduction	No change No change
4	DDT 12 5	Negligible	Very thick grass cover, numerous tall trees	No change	No change
5	DDT 15 0	*c* 5 m p h	Sparse grass, some bushes	Very heavy reduction	Rather heavy reduction
6	DDT 15 0	Light	Sparse grass, no bushes	Heavy reduction with numerous dead larvæ	Heavy reduction, no dead larvæ

* Two runs in opposite directions were made along the same track in order to double the rate of application

severely interrupted by the numerous trees so that dispersion of the spray was unsatisfactory. Secondly, the heavy grass cover, in places 9 in. deep, caused dilution of the spray in terms of quantity per unit volume of vegetation.

In test 5, the results were confused by a nuclear polyhedrosis which caused a pronounced reduction on the controls. Although the decrease was greater on the treated area, the spray was obviously applied to a debilitated population and had only enhanced the action of the disease.

Test 6 was difficult to assess, as heavy reductions had occurred on both treated and untreated areas. However, on the control, the reduction was due entirely to pupation and no dead larvæ could be found on the surface; on the treated area, although pupation may have had some effect, many dead larvæ were found on the surface. The treatment may therefore be regarded as having caused a diminution in numbers.

The distribution of live larvæ after treatment accorded well with the observed distribution of spray recorded by Courshee[3]. In tests 2, 3 and 5, no deaths due to spraying occurred within 5 yd. of the spray track; mortality then increased to a peak at 30–50 yd. where very few live larvæ could be found, and beyond this limit decreased more slowly to become negligible 100–110 yd. from the spray track.

Should further tests fulfil the promise of those conducted, we believe the exhaust sprayer will have great value in the control of *L. exempta* and other 'army worms' on grazing. Its use is limited by the nature of the vegetation only in that the presence of too many trees interrupts air movement and too thick a grass cover causes excessive dilution. Its value lies in its low capital cost, low running costs, speed, and manœuvrability.

We envisage two uses for the sprayer: (1) it can be used to provide a barrier between infested and uninfested grazing along a wide front; (2) it can be used to eliminate infestations from paddocks by parallel spray runs at intervals of 75–100 yd. In this latter case, using a cost of 20*s.*/gall., a rate of application of 4 gall./mile, and a distance between runs of 75 yd., the spray would cost 3*s.*/acre plus the running costs of the vehicle.

We are grateful to the Director of the Desert Locust Survey, Nairobi, for the loan of the exhaust sprayer, and for the advice given by him and his staff on its use.

SOIL SCIENCE

Influence of Some Organic Salts on the Absorption of Potassium by Vermiculite

A MARKED effect of the ammonium ion on release and fixation of potassium by vermiculite has been shown by many workers. The presence of ammonium ions in an extracting solution inhibits the removal of potassium which has been absorbed or fixed in vermiculite. The fixation of potassium by vermiculite is also reduced if the solution contains ammonium ions. The effect of the ammonium ion on potassium reactions is presumably due to the similarity of the two ions with respect to their size and chemical reactivity. Both ions are known to have an optimum ionic diameter for fixation within the vermiculite lattice. In the presence of ammonium ions the vermiculite lattice apparently is contracted so that potassium ions can neither enter nor leave the internal vermiculite surfaces.

The influence of other nitrogen compounds on potassium absorption by vermiculite was considered. The term 'absorption' is used here in preference to 'adsorption' since most of the effects noted here are associated with the internal surfaces of the vermiculite mineral. The compounds used in this work were amines of various kinds which may be considered in a sense as analogues of the ammonium ion in that one or more of the hydrogen atoms around the nitrogen are replaced with organic groups of various kinds. The substitution of organic groups for the hydrogens of the ammonium ion of course results in great changes in the properties of the ion.

Two types of investigations were made. One was concerned with the effect of the organic salts on the rate of potassium absorption by vermiculite, the other with the effect of organic salts on the amount of absorption under conditions where equilibrium could be approached. The vermiculite used in this work had a cation exchange capacity of 160 m.equiv./100 gm.

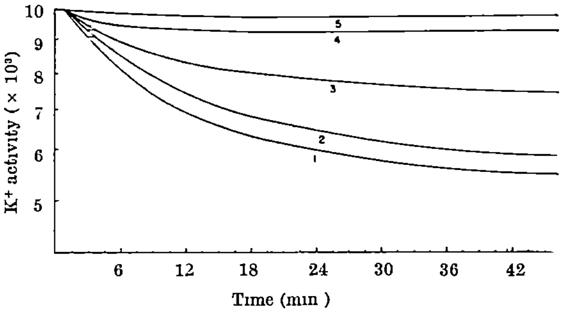

Fig. 1. Potassium activity in the presence of 0·25 gm. of 150–250μ diameter vermiculite as a function of time at 20° C. 1, No other salt; 2, 1 m.equiv. of *n*-butylamine hydrochloride; 3, 0·1 m.equiv. 2,4-diaminophenol dihydrochloride; 4, 1 m.equiv. aniline hydrochloride; 5, 1 m.equiv. 2,4-diaminophenol dihydrochloride

Fig. 1 shows the effect of some organic salts on the activity of potassium in the presence of vermiculite as a function of time. The activity measurements were made continuously with the 78137 *V* cationic electrode produced by Beckman Instruments, Inc., in combination with a Beckman Zeromatic *p*H meter and a Sargent recorder. The potassium chloride solution was stirred continuously with a magnetic stirrer. After the recorder deflexion was static, the organic salt was added. There was only a small effect of the organic salts on the potassium ion activity since the amount added was not enough to affect the activity coefficient of the potassium ion a great deal. Also the electrode was insensitive to the organic ions used although it was found to be sensitive to the presence of ammonium ions. At zero time 0·125 gm. of vermiculite was added. A short lag time of about 1 min. is apparent in Fig. 1 before the potassium started disappearing from solution. This lag time was noted

Table 1 001 Spacings of Vermiculite after Contact with Potassium Chloride in the Presence of Various Salts

Compounds	M equiv of compound present	Vermiculite (gm)	M equiv of KCl present	Hr contact	001 spacing (Å)
None	—	0 25	0 5	2	12 1 and 10
2,4-Diaminophenol dihydrochloride	1 0	0 25	0 5	2	14 5
2,4-Diaminophenol dihydrochloride	0 1	0 25	0 5	2	14 3 and 12 6
Aniline hydrochloride	1 0	0 25	0 5	2	14 5
n-Butylamine hydrochloride	2 0	0 25	0 5	2	12 1 and 10
n-Butylamine hydrochloride	1 0	0 25	0 5	2	12 1 and 10
n-Butylamine hydrochloride	0 1	0 25	0 5	2	12 1 and 10
p-Phenylene diamine dihydrochloride	0 25	0 125	0 25	48	14 5–13 0
Histidine hydrochloride	0 25	0 125	0 25	48	13 8–12 3
Ammonium chloride	0 25	0 125	0 25	48	11 3 and 10
Lysine hydrochloride	0 25	0 125	0 25	48	11 3 and 10

in all cases and is probably the time required for the complete wetting of the mineral The magnesium ion was initially the saturating cation on the exchange complex of the vermiculite, the electrode being insensitive to this ion

The main observation to be made is that *n*-butylamine hydrochloride (curve 2) had little effect on the rate of absorption of potassium as compared with the rate when no organic salt was present (curve 1) On the other hand, 2,4-diaminophenol dihydrochloride (curves 3 and 5) and aniline hydrochloride (curve 4) greatly affected potassium absorption The 2,4-diaminophenol dihydrochloride added at the 0 1 m equiv -level (curve 3) reduced absorption of potassium vermiculite much more than did 1 0 m equiv of *n*-butylamine hydrochloride (curve 2) The 001 spacings of vermiculite obtained by X-ray diffraction 2 hr after the absorption reactions began are given in Table 1

Table 2 shows the amounts of potassium absorbed from solution by sodium-saturated vermiculite in the presence of various organic salts, ammonium chloride, and in the instance when no foreign salts were present These analyses were made on the solution phase with a Coleman flame photometer after 48 hr were allowed for absorption Large differences are apparent in the effects of organic salts on potassium absorption Particularly noteworthy is the fact that the *n*-butylamine hydrochloride had no effect whatsoever on potassium absorption at either of the two concentrations Also, as noted in Table 1, the 001 spacing of the lattice has contracted in exactly the same manner as where only potassium chloride was present On the other hand, some of the amines. particularly those with a cyclic molecular structure, greatly inhibited the absorption of potassium. Apparently the number of electrical charges per molecule was not too important since the aniline hydrochloride was about as effective as 2,4-diaminophenol dihydrochloride and para-phenylenediamine dihydrochloride in preventing potassium absorption Of the three amino-acid salts examined, histidine monohydrochloride was the most effective in inhibiting absorption Histidine possesses a ring structure while the other two amino-acids used are linear in form Histidine was almost as effective as the ammonium ion in preventing potassium absorption.

Table 2 Absorption of Potassium by Vermiculite in the Presence of Some Salts*

Salt	M equiv K absorbed/100 gm Salt/KCl ratio 0 1	 1 0
n-Butylamine hydrochloride	120	120
2,4-Diaminophenol dihydrochloride	108	36
Aniline hydrochloride	106	32
p-Phenylenediamine dihydrochloride	108	28
Tetramethylammonium chloride	118	100
Histidine monohydrochloride	112	58
Arginine monohydrochloride	108	96
Lysine monohydrochloride	120	88
Ammonium chloride	106	52
None	120 m equiv K^+/100 gm absorbed when no other salt was present	

* Absorption by 0 125 gm vermiculite in 200 ml of 1 25 × 10^{-3} *N* KCl after 48 hr at 20° C Each figure is the average of analyses of duplicate samples with extremely low variation between duplicates

Apparently the organic molecules which affect potassium absorption do so in a manner different from that of the ammonium ion Table 1 shows that the 001 spacing of the vermiculite collapsed to spacings of 11·3 and 10 Å in the presence of ammonium chloride However, the lattice remained pretty well expanded in the presence of the organic molecules which effectively prevented absorption Those organic molecules which did not greatly affect potassium absorption allowed a greater amount of potassium to enter the internal surfaces This resulted in a greater degree of contraction of the lattice as shown by the smaller values of the 001 spacings The potassium thus entrapped in the internal surfaces of the contracted lattice of the vermiculite was fixed and was not exchangeable under ordinary conditions of cation exchange

Since the vermiculite lattice was fully expanded in the presence of those organic cations which most effectively prevented potassium absorption, these ions undoubtedly prevent the entrance of potassium ions into the internal surfaces of the vermiculite structure This could be accomplished if the energy of adsorption of the organic ion were so large that the potassium from the solution phase could not exchange with the organic cation at the edges of the mineral. The potassium thus would not be able to move into the interlayer spaces Undoubtedly the mechanism of cation movement into the lattice is diffusion along cation exchange sites[1] In order for this to occur, the potassium must be able to exchange with other ions on the cation exchange complex If the cation exchange complex were 'clogged' with ions which potassium could not displace, the potassium would be unable to enter the internal vermiculite surfaces

In soils, a large number of different kinds of organic molecules appear as the result of the decomposition of organic matter Some of the organic molecules used in this work were more effective than the ammonium ion in preventing potassium absorption, while histidine, a possible product of decomposition of organic matter, was almost as effective as the ammonium ion Organic molecules may play an important part in the release and fixation of potassium by vermiculitic clays in soils The complete lack of effect of the *n*-butylamine ion on potassium absorption was anomalous since all the other compounds used in these experiments had some effect This amine apparently did not compete with the potassium for cation exchange sites

The apparent interaction of organic compounds in potassium reactions with vermiculite may be of importance in soils containing this mineral Fixation. and possibly release of potassium, may be modified by the presence of certain organic compounds

Thursday, November 9

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr H Judith Milledge "Form and Colour in Nature" *

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W 1), at 4 30 p m —Mr M J Lighthill, F R S "Sound Generated Aerodynamically" (the Bakerian Lecture)

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W 1), at 5 p m.—Dr Wm T Stearn "Some Puzzling Linnean Abbreviations", Mr P. R O Bally "The Retreat of Nature in Modern East Africa"

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W C 2), at 5 15 p m —Dr Harold Heywood "New Developments in the Use of Solar Energy"

UNIVERSITY OF LONDON (at King's College, Strand, London, W C 2), at 5 30 p m —Prof J Meixner "On the Theory of Linear Passive Systems".* (Last of three Special University Lectures)

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMATIC CONTROL GROUP (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Brains Trust on "Automatic Control" (Inaugural Meeting)

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W 1), at 7 p m —Dr R S Teeble "Applications of Microwave Spectroscopy"

RADAR AND ELECTRONICS ASSOCIATION (in the Lecture Hall of the Royal Society of Arts, John Adam Street, Adelphi, London, W C 2), at 7 p m.—Dr W. F Hilton "Space Communications Part 2 Orbits and their Economics".

ROYAL INSTITUTE OF CHEMISTRY (at Croydon Technical College, Fairfield, Croydon, Surrey), at 7 30 p m.—Mr R B Collins "Modern Colour Photographic Processes".

Friday, November 10

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Prof F Fenner (Australian National University) "Myxomatosis—a Study of Evolutionary Changes in an Infectious Disease" *

UNIVERSITY OF LONDON (at the Royal Holloway College, Englefield Green, Surrey), at 8 15 p m —Mr William Cooper "Science and Literature"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 9 p m —Prof W S Bullough "Modern Research on the Skin of Mice and Men"

Saturday, November 11

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Dr E J Lindgren "Reindeer Farming in Europe, Asia, and North America" *

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ASSISTANT LIBRARIAN (graduate with some library experience)—The Secretary and Registrar, The University, Highfield, Southampton (November 11)

LECTURER or ASSISTANT LECTURER IN PURE MATHEMATICS—The Registrar, The University, Sheffield (November 11)

LECTURER or ASSISTANT LECTURER (preferably a specialist in the field of human geography with first-hand experience of a major overseas area outside Europe) IN GEOGRAPHY—The Registrar, The University, Leeds 2 (November 13)

SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (honours graduate with appropriate training and research experience), to work as a member of a team undertaking research on hill sheep nutrition—The Secretary, Hill Farming Research Organisation, 48 Palmerston Place, Edinburgh 12 (November 13)

LECTURER in EXPERIMENTAL PHARMACOLOGY—The Secretary of University Court, The University, Glasgow (November 15)

LECTURER IN PSYCHOLOGY at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, November 15)

ASSISTANT LECTURER or LECTURER IN ANIMAL HUSBANDRY—The Registrar, The University, Liverpool, quoting Ref CV/T (November 18)

LECTURER IN CYTOLOGY IN THE DEPARTMENTS OF BOTANY AND ZOOLOGY in the Faculty of Science—The Registrar, The University, Manchester 13 (November 18)

LECTURER or ASSISTANT LECTURER IN STATISTICS—The Registrar, The University, Sheffield (November 18)

SCIENTIFIC ASSISTANT (with at least G C E at "O" level in four subjects, including geography, with an interest in biology and a capacity for neatness and precision), for recording and mapping reported movements of locust swarms, copying-maps, and generally assisting in the geographical work of a small team—The Director, Anti-Locust Research Centre, 1 Princes Gate, London, S.W 7 (November 18)

LECTURER (with an interest in electronics or telecommunications) IN ELECTRICAL ENGINEERING at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 29)

CHAIR OF PHILOSOPHY IN THE SCHOOL OF GENERAL STUDIES, Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, November 30)

LECTURERS IN THE DEPARTMENT OF PHYSICS, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W.1 (South Africa and London, November 30)

PROFESSOR OF EXPERIMENTAL PHYSICS—The Registrar, The University, Nottingham (November 30)

READER or SENIOR LECTURER IN ARCHÆOLOGY at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 30)

LECTURER IN SEDIMENTARY PETROLOGY, to initiate and direct research on sedimentation in Cardigan Bay and St George's Channel, as part of an investigation into the origin and geological history of this region—The Registrar, University College of Wales, Aberystwyth (December 15)

LECTURER or ASSISTANT LECTURER IN THE HISTORY OF SCIENCE at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 31)

AGRICULTURAL OFFICERS (male, with a degree in agriculture or horticulture and at least two years postgraduate experience) IN THE DEPARTMENT OF AGRICULTURE, Tanganyika, for extension work among both African and non-African farmers and experimental work on agricultural stations—The Director of Recruitment, Department of Technical Co-operation, Carlton House Terrace, London, S.W 1, quoting RC 213/145/01/C1

ASSISTANT CHEMIST (male or female, with H N C in chemistry or biochemistry or an equivalent qualification), for routine and development work—The Secretary, Wright–Fleming Institute of Microbiology, St Mary's Hospital Medical School, London, W 2

BIOCHEMIST (Basic grade) IN THE DEPARTMENT OF ENDOCRINOLOGY—The Hospital Secretary, New End Hospital, London, N W 3

COCOA OFFICER (male, under 45, with a degree in agriculture, preferably in cocoa extension or development work) IN THE DEPARTMENT OF AGRICULTURE, British Solomon Islands Protectorate, to assist in cocoa development and extension of cocoa planting and processing—The Director of Recruitment, Department of Technical Co-operation, Carlton House Terrace, London, S W 1, quoting RC 213/18/02/C1

FISHERIES OFFICER (male, qualified biologist with an honours degree in a natural science, preferably zoology, and experience in research work) in Tanganyika, to investigate the ecology of inland waters in relation to fish production—The Director of Recruitment, Department of Technical Co-operation, Carlton House Terrace, London, S W 1, quoting BCD 63/8/012/C1

HEAD (man or woman, honours graduate, preferably in physics) OF THE SCIENCE DEPARTMENT—The Headmistress, Sherborne School for Girls, Dorset

RESEARCH ASSISTANT (British Empire Cancer Campaign) (biochemist, preferably holding a Ph D , with experience in enzymology), to work on the effects of steroids on tissue metabolism—The Department of Chemical Pathology, Royal Free Hospital, London, W C 1

RESEARCH OFFICERS (FISHERIES) (male, under 40, with an honours degree in natural sciences or equivalent qualification, together with at least one year's postgraduate experience in appropriate research work) IN THE CO-OPERATIVE DEVELOPMENT AND FISHERIES DEPARTMENT, Hong Kong, for duty with a research team investigating the fisheries of the South China Sea, and to supervise the work of Assistant Research Officers—The Director of Recruitment, Department of Technical Co-operation, Carlton House Terrace, London, S W 1, quoting RC 289/68/01/C1

RESEARCH OFFICERS (with a first- or second-class honours degree in chemistry, biochemistry or chemical technology, or equivalent qualification, plus at least two years postgraduate experience) with the Federal Government of Nigeria, to carry out laboratory research and development work on Nigerian raw materials—The Recruitment Attaché, Nigeria High Commission, 9 Northumberland Avenue, London, W C 2, quoting Ref E 14/1

SENIOR LECTURER (man or woman) IN EDUCATION—The Principal, Radbrook College, Shrewsbury

CONTROL OF GOVERNMENT EXPENDITURE ON RESEARCH

THE Council for Scientific and Industrial Research, since its constitution some four years ago, has been concerned with the most effective means of budgetary control of scientific research in Britain In its 1958 report the Council pointed out that, while it was possible to estimate research needs fairly accurately two years ahead, this could only be done provisionally five years in advance, and, accordingly, the Council sought as much flexibility as possible in allocating the funds at its disposal A year later the Council stated that the Treasury had agreed that, without prejudice to the rest of the five-year plan to which the Council seeks to work, the Council might enter into commitments for research grants at a substantially higher level than was possible with the sums provided in the plan and that this level should be reviewed year by year

In the Council's latest report, this policy was taken a stage further and the introduction was announced of an experimental scheme which should be more adaptable to rapid and unpredictable change Under it the Council proposes each year to try to forecast its needs for five years in advance and to agree with the Treasury, subject to approval by Parliament, first the expenditure for the following year, secondly, reasonably firm estimates for the two succeeding years, and thirdly, less-definite estimates for the fourth and fifth years This means that each year the estimates will be raised and brought forward one year, so that expenditure of each year will be planned against a fairly clear indication of probable expenditure in the years immediately following and with some regard to longer-term plans Major departures from the estimates for the second and third years would only be made if there were important unforeseen changes in the scientific or financial situation

This scheme seems to meet one comment made by the Select Committee on Estimates in its Fifth Report for the Session 1957–58, reviewing the work of the Department, when the Committee expressed the view that the timing of the termination of a piece of research could be as important as the timing of its initiation, and welcomed the Department's practice of regular reviews, not tied to the approval of the annual programmes, working independently of the advisory boards of the establishments Strong support for this more flexible policy is now forthcoming from the Committee which, under the chairmanship of Lord Plowden, reported last June on the *Control of Public Expenditure** This support is perhaps the more significant, first because although the Plowden Committee was not appointed to deal specifically with scientific or technical expenditure, it quickly distinguished the difficulties which characterize the control of such expenditure to-day, and secondly, because the difficulties encountered by the Council for Scientific and Industrial Research arise not simply from the mounting cost of scientific work but also from the effect of interlocking decisions taken elsewhere, as in educational policy, or in the fields of fuel, power, communications, space research, and the like

Under the traditional system in Great Britain, as it developed in the nineteenth century and has continued throughout the lifetime of successive Governments to the present day, the tendency is for decisions on expenditure to be taken piecemeal It is increasingly apparent that, where science and technology are concerned especially, this system is wasteful and liable to cause frustration and waste of resources of finance and material as well as of man-power This is fully recognized by the Plowden Committee, and the core of its proposals is the development and use by Government of long-term surveys of expenditure and resources.

The report is, in fact, a State paper of outstanding significance which deserves—and indeed demands—close study by all who are concerned with the public finance of research and development and the most effective allocation of available resources It is a sequel to an earlier report on Treasury Control of Expenditure from the Select Committee on Estimates in 1958, and the Committee was appointed in the summer of 1959 Several confidential reports have already been submitted to the Chancellor of the Exchequer Mr Selwyn Lloyd, and his predecessor, and the present report is a consolidation of those suitable for publication and discusses more especially the principles and practice of the control of public expenditure It should stimulate exactly that constructive thinking and foresight which are imperative in dealing with many of the proposals for research and development projects to-day. In the judgment of the Committee, the crucial questions are not those of detail—the precise nature of the organization and chains of command within and between Departments, important though these are The real problems are the wider issues of the purpose which the Government organization is attempting, its attitudes, what it regards as important, and its approach to its work on all matters involving public expenditure Such issues are not always clear-cut, nor do they lend themselves readily to specific recommendations, but the scientist or administrator who reads this report side by side, for example, with the concluding passages of Sir Charles Snow's *Science and Government*, may find it a suggestive experience, for the whole report is designed to indicate fruitful lines of development in the future

At the outset the Committee pays a handsome and deserved tribute to the work of the Civil Service which scientists should note. Changes, both in scope and character, in the activities of Government during the past two decades have produced strains in traditional structures and practices, and Lord Plowden and his colleagues have been impressed by the way the Civil Service has adapted itself to deal with these changes In particular, notable progress has been made in inter-departmental co-operation there is a growing realization that in place of single departments dealing with individual problems in comparative isolation, the public interest requires a team pursuing its common objectives with a single purpose. This attitude of mind, and the readiness to initiate changes to improve control of expenditure, were manifested throughout the discussions between the Committee and the permanent secretaries and other officials of the major Departments Furthermore, members of the Committee with experience of industry and commerce, and the specialist advisers who joined them for the purpose, consider that the scale and quality of effort directed to the provision of management services in Whitehall compare favourably with standards outside Departments with nation-wide organizations appear to be conducted with real appreciation of the scope for application of management services

---

* *Control of Public Expenditure* Pp 33 (Cmnd 1432) (London H M S O, 1961) 1*s* 9*d* net

The report deals, first, with the system of making decisions about Government expenditure, next, with the responsibilities of the Departments and of the Treasury in handling expenditure, and thirdly, with the question of Parliamentary control; while a final section contains some concluding observations on the future management of public expenditure The central problem is that of how to bring the growth of public expenditure under better control and contain it within such limits as the Government may think desirable This is the matter to which the Plowden Committee devoted most attention, and it is important that it should be clearly understood that its report is concerned with the control of expenditure within the limits laid down by policy, and not with the use of finance to concert policy In practice, the piecemeal decisions which the Plowden Committee criticizes can have the effect of confining or impeding policy, and the definite conclusion is reached that decisions involving substantial future expenditure should always be taken in the light of surveys of public expenditure as a whole, over a period of years, and in relation to the prospective resources Admittedly, judgments of the relative importance of one kind of expenditure or another may differ, but much of the criticism of Government expenditure in the scientific and technological field would lose its force if more care were taken to provide public opinion with the means for sound, informed judgments

The new situation is attributed to the social, political and economic changes of the past two decades. Supply expenditure is now 22 per cent of the gross national product, compared with 12 per cent in 1930 and 6 per cent in 1910, while the public sector of the economy as a whole now employs about one-quarter of the total labour force and public expenditure of all kinds represents about 42 per cent of the gross national product Moreover, its increasing complexity, including the cost of advanced technological projects and scientific research, the financing of commercial risks that the private sector cannot take, aid of many kinds to under-developed countries and social insurance schemes of unprecedented scope, involve commitments several years ahead Further, the Budget is now seen as a sophisticated process in which the instruments of taxation and expenditure are used to influence the course of the economy, and the main weight of Parliamentary and public pressure is for innovations and improvements which cannot be effected without increases in public expenditure

To meet this situation, the Plowden Committee favours a reconstruction based on four elements. regular surveys of public expenditure as a whole, over a period of years ahead, and in relation to prospective resources, decisions involving substantial future expenditure being taken in the light of these surveys, the greatest practicable stability of decisions on public expenditure, so that long-term economy and efficiency throughout the public sector have the best possible opportunity to develop, improvements in the tools for measuring and handling public expenditure problems, including in particular major simplification of the form of estimates, modernization and clarification of the Exchequer accounts, and more widespread use of quantitative methods in dealing with these problems throughout the public service; and more effective machinery for taking collective decisions and the bearing of collective responsibility by Ministers on matters of public expenditure

One advantage of stability in expenditure policy noted in the report is regarded as the most important of all, although often overlooked. Such stability encourages sound planning by the Departments before the Government decision is sought. There is less danger of projects being rushed to decision to take advantage of a favourable event without being first subjected to adequate financial examination or measurement against other projects or means of securing the same purpose That, and failure to fit the project into a rational expenditure pattern, can lead to great waste, and the major proposals in the first two parts of the report are intended to strengthen the organization against faulty decisions of all these types On that ground alone they deserve close study by the scientist, for it is frequently in situations that arise out of scientific advance or technological change that the Government is required to act quickly and effectively and in the face of what appears to be great urgency, fanned by Parliamentary and public opinion Apart from improving the control of public expenditure, they could provide a real safeguard against such pressure leading to undue support in one sector of science or technology rather than another

The Committee's proposals are also designed to lead gradually to greater public interest in the priorities of expenditure, to stimulate academic thought about it, and to greater awareness of the implications and choices involved in policies as they come forward. The Committee emphasizes, in conclusion, the importance of building up an informed public opinion on the whole subject Public opinion has probably now come to accept that public expenditure and private expenditure both have their place in the national life, and that what is required is a balance between them There are differences of opinion as to where that balance should be, nor is the balance easy to find, for insufficient is known as to the relation of public expenditure to the issues of growth and solvency of the national economy Any Government, however, may find it difficult to maintain whatever balance it believes to be right in the face of the pressures, always powerful, to increase public spending in the modern community, and the best system and most up-to-date techniques of control will only succeed if public opinion is actively stimulated and enabled to take a balanced view of the alternative uses of national resources that are put forward, and to bring to the consideration of problems of public expenditure and resources the same qualities of common sense and realism that the average household shows all the time in handling its own affairs

As regards the tools of control of expenditure, proposals for a new lay-out for the Estimates have already been made by the Committee and these were published in a Treasury Memorandum included in the Third Report from the Estimates Committee for the Session 1960–61* The Government has already accepted the Plowden Committee recommendation for these changes, and the present report merely directs attention to one feature of the new lay-out, which includes for the first time for each Vote a statement showing how the total is divided between the categories used in the analysis in the National Income and Expenditure Blue Book The Treasury has also begun a review of the form of Exchequer accounts, but generally the Plowden Committee received the impression that insufficient study had been given both inside and outside Whitehall to the effect of the size and composition of public expenditure on the growth and solvency of the national economy, nor have clear criteria been established to permit a rational choice to be made between different kinds of expenditure

Developments envisaged in this report will call for a wider application of mathematical techniques, statistics and accountancy to problems of public expenditure, and there may also be scope for the use of the techniques generally described as operational research Stress is laid on the advantage of seizing every opportunity for interchange of ideas and experience in management with people in industry Further, since Parliament and public opinion no longer apply as systematic a restraint to public expenditure as they did in the past, the Plowden Committee suggests that some improvement is required in the arrangements to enable Ministers to discharge their collective responsibility for the review of public expenditure as a whole. Apart, however, from its stress on the importance of efficient management, the report makes some comment on Parliamentary control, though it does not go deeply into the relations between Parliament and the Executive in the control of expenditure Here its main purpose is to show how Parliament's influence and authority can best be brought to bear constructively and in this respect it is the complement of Basil Chubb's book under the same title, just as the major part of the report is a natural counterpart of Prof S H Beer's study, *Treasury Control*

There is thus much in this report that needs careful study by those concerned with the organization of Britain's research effort, whether in the purely scientific or the technological field The report supports some of the proposals of the Select Committee on Estimates in its Sixth Report for the Session 1957–58, but it would be interesting to see the report of Sir Claude Gibbs's committee on managing and controlling research projects The emphasis on the interlocking of public expenditure, for example, should be particularly noted, while the affirmation that in terms of administration it is unwise ever to attempt to make reductions or expansions in public expenditure by a process of equal percentage subtractions or additions all round will be warmly welcomed Departments cannot sensibly be treated equally, and steady or falling expenditures require just as careful examination as those which may be rising

In view of these pronouncements and the further emphasis on stability of expenditure, it is startling to find that the Council for Scientific and Industrial Research has suddenly, following the measures announced by the Chancellor of the Exchequer on July 25, suspended five major new grants that are imminent In the statement making this announcement, which concerns the grants for the nuclear reactors for Scottish universities, and for the Universities of Liverpool and Manchester jointly, and the University of London, respectively, and for two radio telescopes for the Universities of Manchester and Cambridge, the Council expresses concern that, in view of the exceptional rate of expansion in numerous fields, the demands on its funds for 1962–63 are likely to exceed the planned resources Until consideration of the detailed estimates for 1962–63 is complete, the Department is unable to enter into new major commitments

The manner in which the announcement was made, however, suggests that an element of high politics has prevailed, all the more in that, as noted already, the Department has hitherto been almost unique among Government departments in using the system of estimates of expenditure for five consecutive years in advance On the face of it, the Council, whether yielding to higher pressure or not, is departing from its own practice and flouting the unequivocal recommendation of the Plowden Committee Much, of course, depends on how long the suspension proves to be The projects are all the outcome of discussions between the universities and the Department, and it will not escape notice that meanwhile the radio-telescope for the Radar Research Establishment at Malvern is unaffected Long delay with the projects could warp development in two fields of science in which Britain has established a leading position It is, in any event, difficult to reconcile the announcement with the need to consider long-term requirements as well as the present situation which the Plowden Committee rightly stresses An early examination of the position by, and an authoritative statement from, the Minister for Science, who apart from this should be studying the Plowden Report with some care and urgency, seem imperative

---

* Third Report from the Estimates Committee together with part of the Minutes of Evidence taken before Sub-Committee A, and Appendix Session 1960–61 Pp vi+58 (London H M S O, 1961) 4s 6d net

That is the more important if the informed public opinion on which the Plowden Committee rightly insists is to be built up, for full and accurate information is an essential basis for public confidence and sound judgment The point is the more significant in that in what is probably the weakest passage of the report, the Plowden Committee swings right against its concluding emphasis on informed public opinion and appears to endorse a policy of withholding from publication the long-term surveys of expenditure, prospective development of income or economic resources Unless the maximum information is supplied, informed discussion of the issues is impossible neither the perspective nor the basis for sound judgment is available, and Lord Hailsham might well reflect as regards the recent announcement by the Council for Scientific and Industrial Research, that in the case of departures from accepted policy, frankness and full publicity are the more essential Secrecy is no basis either for confidence or sound judgment

PARASITES OF MAN

Introduction to Parasitology, with special reference to the Parasites of Man.

By the late Prof Asa C Chandler and Prof Clark P Read Tenth edition Pp xii+822 (New York and London John Wiley and Sons, Inc , 1961) 78*s*

THE appearance of yet another edition of this well-known book will be welcomed by all parasitologists, but their welcome will be greatly saddened by the knowledge that Asa Chandler, whose long life was devoted to the study of parasites and to the alleviation of the suffering caused by them to man and other animals, died while he was in the act of preparing this new edition His great achievements in research and the devoted service he gave to human and veterinary medicine, and also to biology in general, will always be remembered by workers in these fields all over the world, for Chandler laboured, and was well known, in many countries, and the long list of his publications proves not only the width of his biological interests but also the practical value of the detailed work he accomplished

In 1918 he embodied his knowledge and experience in a book entitled *Animal Parasites and Human Disease*, the fourth edition of which was, in 1930, rewritten to provide a general introduction to parasitology , and the value of this second work was proved by the demand for further editions of it, its title being changed, in 1940, to its present form Now, in this tenth edition, we are given the revision prepared by Prof Clark Read, who has succeeded Prof Chandler in the chair of biology at the Rice Institute, Houston, Texas Prof Clark has, he tells us in his preface, taken over full responsibility for the chapters on the Protozoa and the helminths, that is to say, for 512 of the 796 pages of text, and he has rewritten the chapters on the arthropods with the aid of notes left by Prof Chandler

The result is a volume which fully maintains the high standard of the earlier editions It deals primarily with the parasites of man, but references are also made to parasites of domesticated and other animals, especially to those which are important in one way or another to human life and affairs A notable change, which some readers will perhaps regret, is the deletion of the chapter on spirochætes, these organisms being now treated in a chapter on arthropod-borne organisms other than Protozoa, which also deals with the viruses, bacteria, *Rickettsiae* and the group of organisms of uncertain systematic position, such as *Anaplasma, Eperythrozoon, Grahamella, Bartonella and Haemobartonella* Systematics have never been emphasized in this book, though necessary classifications, not always those favoured by English workers, are given, together with keys for the identification of species The book has, in fact, always been remarkable for its exposition, in lively but not abstruse language, of the principles of parasitology, though it has always contained at the same time a great deal of detail cunningly woven into the text Prof Clark has maintained this combination of attractive style and detail and the text is now as up to date as any book, in these days of very rapid advances in knowledge, can hope to be. The references appended to each chapter and the list given of journals in which advances of knowledge are recorded, add, as the good index and the abundant illustrations also do, to the value of the book Prof Clark is to be congratulated on his careful and competent completion of what must have been a difficult job G LAPAGE

TREES OF CONSEQUENCE

The Eucalypts

Botany, Cultivation, Chemistry, and Utilization By A R Penfold and J L Willis (World Crop Books) Pp xx+551+61 plates (London Leonard Hill (Books), Ltd ; New York Interscience Publishers, Inc , 1961) 80*s* net

SOMEONE reviewing a recent world conference in Brazil on eucalypt-growing made the rather sombre observation that the Earth is becoming covered with eucalyptus trees The first specimen known to science was collected less than 200 years ago at Botany Bay on Captain Cook's first voyage, and now plantations throughout the world are estimated to cover 3½ million acres The award of a volume in the series of World Crop Books is a mark of recognition of this success-story The genus owes its progress equally to its versatility and its utility One species or another can be provided to suit a wide range of habitats, often growing with remarkable vigour and sometimes in places which other trees find discouraging

The genus *Eucalyptus* is reckoned as having more than 500 recognizable species, of which many are of economic value In discussing eucalypt as a crop-plant, it is essential that we be clear what species we are concerned with, and inevitably much of this book is taken up with botanical descriptions and means of distinguishing one species from another The first few chapters contain an account of the genus, the characters of stem, flower and fruit. This leads up to sub-division of the genus and classification of the species, in which the system devised by Blakely is adopted.

The central part of the book deals with the eucalypts as crop-plants, their cultivation, their introduction as a forest-crop in many countries, the diseases and pests to which they are subject In discussing its uses, the authors acclaim the genus as the most valuable source of hardwood in the world, good for structural work, for furniture, for sporting goods (Can those forceful Australian cricket-bats be made of eucalyptus?), for plywood and for fuel No less remarkable in the genus is the wide range of essential oils, on which the authors write with particular knowledge, and from which are derived such varied products as antiseptics, inhalants, perfumes, sheep-dips and stain removers

In the last, and by far the longest, chapter an attempt is made briefly to describe each species, what it looks like, where found, what conditions it needs, and what it is good for The book includes some maps to show where eucalypts grow, an extensive bibliography, a good subject index, and some plates of uneven merit The authors write clearly and competently, handling in orderly fashion a great mass of information This book will prove a valuable guide to all who have to do with the production or products of this great genus, the stature of which as a world crop seems certain to grow mightier yet

COMPUTER DESIGN

Computer Logic

The Functional Design of Digital Computers By Dr Ivan Flores (Prentice-Hall Electrical Engineering Series) Pp xii+458 (London Prentice-Hall International, Inc, 1960) 45*s*

Design Fundamentals of Analog Computer Components

By Prof R M Howe Pp x+268 (Princeton, N J D Van Nostrand Company, Inc, London D Van Nostrand Company, Ltd, 1961) 7 50 dollars, 56*s* 6*d*

THE legend on the dust cover of the first of these books reads "How computers are put together—how they work—how to use them" This describes the book better than the title It is not a text-book on computer design, but is addressed to the general scientific reader of whom a minimum is required in the way of engineering and mathematical background Nevertheless, it contains a very solid treatment of logical design, the binary system, adders, multipliers, control units, input and output devices, magnetic tape, and so on, all will be found described here, together with the usual ration of Boolean algebra and formal logic More attention is paid than in similar books to the mechanical details of input and output equipment

Only a small part of the book is concerned with programming, but this part I found unsatisfactory It seems a mistake, now that modifier registers are the order of the day, to introduce the reader first to the old-time procedure for modifying instructions in the arithmetic unit The last chapter, on programming a particular scientific problem, is a veritable museum piece, and leads one to think that the author must have been entirely insulated from the development of programming techniques It exhibits the most primitive form of machine language coding possible, in which even the conversion of relative addresses in sub-routines to absolute addresses must be done by the programmer himself before his programme is punched In these days, even if a programmer does not use some form of automatic programming, he may expect to have the assistance of a more or less elaborate input programme which provides, among other facilities, automatic relative addressing The book would have been better without the last chapter

The purpose of the second book is to give users of present-day analogue computers some idea of how these machines came to be designed as they were The author believes, quite rightly, that a complete understanding of the capabilities of an electronic analogue computer cannot be obtained without a considerable knowledge of the component details and how they affect the computer solutions The book contains chapters on systems design, component accuracy, d c amplifiers, multipliers, function generators, recorders and miscellaneous equipment An important and valuable feature of the book is the large amount of detailed and comparative design information given about some of the better-known commercially available analogue computers The book is very well written, and those not themselves working in the analogue field may find it interesting as showing the remarkable way in which analogue computers have developed from the primitive devices that they were ten years ago to their modern form

THE BACTERIAL CELL

Synthesis and Organisation in the Bacterial Cell

By E F Gale (Ciba Lectures in Microbial Biochemistry, 1959). Pp vii+110 (New York and London. John Wiley and Sons, Inc, 1959) 3 50 dollars, 28*s*

ACCORDING to *The Times* of August 14, the National Union of Students reported in a memorandum to the Committee on University Teaching Methods that they have received complaints of lectures in universities being ill-prepared, badly presented and giving only what is already available in books One wonders to what extent these criticisms apply to teachers of biochemistry Biochemical research is so prolific and occasionally so disturbing even to basic concepts that an unrevised text-book more than ten years old is scarcely more useful to a final honours student than last term's cell-free bacterial extract It is possible that there exist lecturers who fear that "to be intelligible is to be found out"[1], but the same writer also affirmed that "the truth is never pure and rarely simple"[2]

These three eminently intelligible lectures by Dr Ernest F Gale are concerned with synthesis and organization in the bacterial cell, the truth about which grows increasingly complicated, but he selects, discusses and condenses into a small volume those findings from a vast accumulation of recent research publications which are of real significance The style is lucid, the topics stimulating and the book beautifully presented thus, all readers will admire the electron micrograph of Plate I and the fluorescent micrograph of Plate III. These lectures are a model of how to tackle one difficult task of a lecturer to final-year students, although no doubt such students made up only a very small proportion of his American audience.

This task was to re-assess the findings of ten years ago in the light of those made in the past two. For example, Dr. Gale shows that although many experiments concerned with amino-acid incorporation into disrupted *Staphylococci* contributed to our present knowledge of protein biosynthesis, some of the results were bewildering. Now, they may be interpreted readily since knowledge of the chemical nature of the cell wall has advanced and it is realized that certain amino-acids may be incorporated into substances other than true protein. The lecture reported in Chapter 1 deals with the structure of the bacterial cell, with an account of the cell wall and membrane, and Chapter 2 deals with amino-acid incorporation. Chapter 3, on nucleic acid and protein synthesis, is stimulating but the data are already in need of a second reappraisal. Since the lecture was delivered, the ribosomes in which bacteria are so rich and which excited so much interest a few years ago seem no longer to hold their central place in metabolism as templates for protein synthesis. "Ribosomes are non-specialized structures which synthesize, at a given time, the protein dictated by the message they happen to contain"[3]. As a consequence of the discovery of this type of RNA called 'messenger', Dr. Gale's convenient nomenclature of rna and RNA, according to the size of the molecule, will need revision. It is certain that present discoveries will lead to a tremendous spate of new publications, some of which will no doubt appear to be contradictory, and it is to be hoped that Dr. Gale will be persuaded to survey the field of protein biosynthesis again in about a year's time if only to lighten the burden of the harassed lecturer and his critical, if not angry, young audience.

The book contains few errors. A glucosyl residue in Fig. 2 lacks a hydroxymethyl group, while the apt quotation from Sir Thomas Browne omits whales from the list of prodigious pieces of Nature given in the first authentic edition of *Religio Medici* (1643) and states that the civility of the little citizens more nearly ('more neatly' is correct) "sets forth the wisdome of their Maker".

POLYMER CHEMISTRY

Preparative Methods of Polymer Chemistry

By Wayne R. Sorenson and Tod W. Campbell. Pp. viii + 337. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1961.) 79*s*.

THE polymer chemist in search of a good method for the laboratory preparation of a particular polymer has in the past been obliged in many cases to carry out a tedious and time-consuming search through *Chemical Abstracts*, all too often with the frustrating result that the desired information is contained in an inaccessible journal. The appearance of a laboratory handbook which collects details of the great majority of polymer-forming reactions and preparative data for a very wide range of polymers will therefore be noted with interest and probably also relief by workers in all branches of this subject.

This cannot have been an easy book to write. The field to be covered is very extensive indeed, it is expanding rapidly, and its sub-division into types of polymer or reaction is not always straightforward. Experimental methods in the literature range from the most meticulous high-vacuum techniques with highly purified materials down to the crudest 'cooking together' in air of commercial-purity reagents, so that the authors must have devoted a lot of thought to selecting the most suitable standards of procedure to adopt in a book of this type. There exists also the difficult problem of the reliability of various published preparations—How is this to be judged? It is therefore greatly to the authors' credit that satisfactory solutions to all these problems have been found.

After a short introductory chapter, some fifty pages are devoted to experimental techniques for the preparation, fabrication and characterization of polymers. The remainder of the book consists of detailed methods of preparation, divided into chapters headed "Polycondensation and Hydrogen Transfer Reactions", "Addition Polymers from Unsaturated Monomers", "Ring Opening Polymerization", "Non-classical Routes to Polymers", and "Synthetic Resins". Each sub-section, containing a number of representative preparations, is preceded by a brief theoretical introduction outlining the principles and mechanisms involved, and giving numerous references to sources of more detailed theoretical treatment. The experimental procedures, although mainly directed to polymer preparation, include quite a few well-chosen examples of reactions on polymers.

The book has many features which deserve favourable comment. The importance of purity of materials is stressed in Chapter 2 and again on numerous occasions throughout the book. The potential danger in many polymerizations is emphasized repeatedly, and where any particular preparation involves special hazard from the type of reaction or the poisonous nature of the materials, this is clearly stated in bold type. The book is very comprehensive, but on those occasions where topics are considered outside its scope, references to other sources of information are given. The lists of references at the ends of the chapters are most extensive, totalling more than five hundred. The methods included are of a high enough standard (with few exceptions) to satisfy everyone but the most demanding research worker, who can easily modify the procedures to suit himself. The details given in the preparations are not the over-abridged accounts which appear in some of our more space-conscious journals, but include numerous helpful comments. The information is thoroughly up to date, few of the latest types of polymer-forming reaction are omitted, except (understandably) in the field of inorganic polymers. In addition to a very good general index, there are indexes by initiator system, reaction system and functional groups. I was impressed also by the clear type, attractive layout and good binding. There are very few misprints.

This is a book which most polymer chemists would find useful. It would also be helpful in connexion with undergraduate courses on practical methods of polymer chemistry. It is an important addition to polymer literature which I recommend highly.

I. C. MCNEILL

Proceedings of the Natural Rubber Research Conference

Kuala Lumpur, 1960 (Sponsored by the Rubber Research Institute of Malaya, with the support of the Government of the Federation of Malaya and the Rubber Producers' Council of the Federation of Malaya) Pp x+986+xix (Kuala Lumpur Rubber Research Institute of Malaya, 1961) 53*s* 8*d*

THIS volume constitutes a comprehensive review of present-day research relating to natural rubber From the opening address the conference faced up to progress in competitive synthetic rubbers and showed from the papers collected in this volume the impressive and many-sided research activities designed to maintain and expand natural rubber production

The longest section, 436 pages, deals with scientific study of *Hevea brasiliensis* with the view of encouraging it to ever greater production of latex Several papers in each sub-section deal with nutrition of the tree, stimulation of latex yield on tapping, ground cover and weed control on the plantation, breeding and selection, pests and diseases A shorter section follows on the production of dry rubber with more stable properties and on modifying its properties at the latex stage or in the manufacturer's factory , a paper herein on factory processing of synthetic *cis*-polyisoprene indicates an absence now of an ostrich-like attitude towards such a synthetic competitor Chemistry and technology of latex occupy most of the remainder of the book

The book is likely to be found by botanists and biochemists to have interest in the individual reports themselves, and as an object lesson in the concerted effort on the one plant both from many disciplines and from many countries Larger libraries collecting the literature of rubber will no doubt obtain it and many rubber technologists will find it interesting to browse through W F WATSON

Elements of Functional Analysis

By L A Liusternik and V J Sobolev Translated from the Russian by Anthony E Labarre, Jr , Herbert Izbicki, and H Ward Crowley Pp ix+227 (New York Frederick Ungar Publishing Company, London Constable and Co , Ltd , 1961) 55*s* net

IN 1936, Liusternik wrote a report on fundamental concepts in functional analysis His summary of methods and results was expanded by Sobolev into a course of lectures, and the resulting account of the elements of functional analysis grew into the Russian edition of this book The date of the Russian edition is not stated, most of it has the air of having been written fifteen or twenty years ago, and the general style and outlook is similar to that of Gelfand, Raikov and Shilov in their work on normed rings (about 1946) which at the time led many mathematicians to appreciate the power of the new methods There is an isolated reference to a paper published in 1958 and a few others to publications of the late 1940's

The first four chapters are devoted to spaces and operators They are clear and concise, and as useful an account as can be found anywhere of what every young functional analyst should know The leading ideas are necessary not only to the functional analyst but also for research in almost any field Chapter 5 introduces the reader to the methods of spectral theory by bounded self-adjoint operators, this will form a good background to the large amount of recent work The mention of non-linear analysis in the title of Chapter 6 leads the reader to expect interesting and important developments, but the chapter is mainly concerned with rather heavy theorems on implicit functions and the calculus of variations J C BURKILL

Theoretical and Experimental Physics

By Dr H G Jerrard and Dr D B McNeill Pp xiv+624+6 plates (London Chapman and Hall, Ltd , 1960) 75*s* net

THIS book is primarily a manual of laboratory work in physics, but has the advantage that it also contains a considerable amount of the relevant theory and about fourteen hundred useful references as well It should be of great value to university students who are studying physics to the pass-degree level and also, in parts, to those taking an honours course in physics

Chapters 1 and 2 are essentially an introduction to the remainder of the book The former has three sections dealing with the representation of experimental results by means of graphs, experimental errors and units (including rationalized M K S units) Chapter 2 is a very useful one and is devoted to a general description of some of the standard apparatus and equipment used in a modern physics laboratory, it is divided into three parts, dealing with optical, electrical and more general apparatus

The remaining chapters, 3–20, then describe experiments in mechanics, properties of matter, heat, acoustics, geometrical optics, physical optics, electricity, electronics and magnetism The presentation in these chapters is a very novel one The right-hand pages contain a description of the experiments while the left-hand pages contain, in smaller type, material of a more advanced nature meant to amplify the work described on the right-hand pages The material on the left-hand pages may be omitted if the reader so desires

The appearance of the book is to be welcomed and it should prove stimulating to both students and to those who teach them D H TREVENA

Bibliography and Index of Geology and Allied Sciences for Wales and the Welsh Borders

1897–1958 By D A Bassett Pp 376 (Cardiff National Museum of Wales, 1961) n p

THIS bibliography covers works on geology and allied sciences that either deal specifically with Wales and the Welsh Border country, or contain references to the geology of these regions The period covered is 1897–1958 Earlier works are listed in several published bibliographies the titles of which are given by the compiler

The book is divided into a number of sections, the principal ones being a list of books, papers, etc , an author-index, and a subject-index There is also a useful section listing unpublished higher degree theses on the geology of Wales The first of these sections is further subdivided chronologically into sections for each year This does not make for ease of reference if, for example, one wishes to consult all the works of a single author, Again, the compilation of a subject-index is a task which must inevitably be affected by the personal equation This one is no exception, and it would be easy to fault it As a whole this bibliography seems somewhat over-elaborate, but nevertheless as a work of reference it will undoubtedly prove valuable to all workers in the field of Welsh geology V A EYLES

A SURVEY OF NEW PENICILLINS

By Prof. ROBERT KNOX
Guy's Hospital Medical School, London, S.E.1

SINCE Fleming's discovery of penicillin in 1929[1] and its later development by Florey and Chain and their collaborators[2] many new antibiotics have been discovered, some of them active against organisms not affected by penicillin, others with a broader spectrum of antibacterial activity. But penicillin (benzyl penicillin or penicillin G) is still in many ways the best. It is effective in minute doses against sensitive organisms, is often bactericidal, almost completely non-toxic, and does not show the rapid development of resistant mutants often seen with other antibiotics such as streptomycin. However, penicillin G is rapidly excreted and comparatively ineffective by mouth, it is liable to give rise to hypersensitivity reactions, sometimes fatal, and the range of its activity is limited—for example, many Gram-negative organisms are insensitive to it. Although most species of organisms do not become rapidly resistant to penicillin G either *in vitro* or *in vivo*, penicillinase-producing staphylococci all over the world have become an increasingly serious menace, especially in hospitals.

For many years it has been known that different types of penicillin were produced by *Penicillium chrysogenum* when cultural conditions were varied. When appropriate precursors were added to the fermentation liquor, as in the production of benzyl penicillin, chemical and microbiological assays of the penicillin formed were in agreement, but when the precursor was omitted from the fermentation liquor a substance was formed which gave the chemical reactions of a penicillin but had much less antibacterial activity. Kato[3] suggested that this was the penicillin nucleus which Sakaguchi and Murao[4] had claimed could be obtained by splitting benzyl penicillin with an amidase. Sheehan[5] reported that he had synthesized the nucleus, 6-aminopenicillanic acid, but the chemical synthesis was difficult and the yields were low. In 1959, Batchelor, Doyle, Nayler and Rolinson[6], at the Beecham Research Laboratories, isolated pure 6-aminopenicillanic acid from fermentation liquors to which no precursor had been added[7–12]. This was a discovery of the first importance and has deservedly been recognized as a major step forward in chemotherapy, both for its practical results and for its theoretical interest. 6-Aminopenicillanic acid could now be obtained in high yield from fermentation liquors with no added precursor. As a result of this work new penicillins are being produced at bewildering speed. Some of these represent important advances in chemotherapy, others are not quite in that class but may have real advantages in special conditions, while others are interesting more because of their theoretical possibilities or because they may serve as prototypes for better models in the future. But there has been a good deal of overlapping and confusion and in some cases the differences are only marginal. It is therefore worth while to survey the present situation and to consider what in fact has been achieved, what reasons there are for expecting further achievements in the future and what light these penicillins may throw on the mode of action of penicillin and the origins of penicillin resistance.

The New Penicillins

It was early realized that there were many penicillins which showed differences in antibacterial activity, for example, penicillin X (*p*-hydroxybenzyl) or K (*n*-heptyl penicillin). But it was soon accepted that the most active for general purposes was benzyl penicillin or penicillin G. At that time when we referred to the 'penicillin' type of antibacterial spectrum we meant the spectrum of penicillin G.

From 1953 onwards penicillin V or phenoxymethyl penicillin came into use[13–15]. It is acid-stable and effective by mouth. It has much the same spectrum of antibiotic activity as penicillin G, but there are differences, some of which may be important.

The first 'synthetic' penicillin was phenoxyethyl penicillin or phenethecillin ('Broxil', 'Syncillin')[16–18]. Like penicillin V it is effective by mouth. The relative merits of phenethecillin and penicillin V have been disputed. Phenethecillin gives higher blood levels than penicillin V, but against most sensitive species of organisms its *in vitro* activity is less. However, phenethecillin is more active *in vitro* than either G or V against some strains of penicillinase-producing staphylococci[19–24].

Shortly after this the discovery of methicillin ('Celbenin')[25–34] was announced. Methicillin was the first penicillin with considerable activity against large inocula of both penicillin G-sensitive and resistant staphylococci. The value of this discovery can scarcely be exaggerated. Methicillin has found an accepted place in the treatment of resistant staphylococcal infections[35]. It has also great theoretical interest. Besides being highly resistant to the action of staphylococcal penicillinase, it is a powerful inducer of the enzyme. Staphylococci are thus stimulated to form the enzyme by an inducer which they cannot use as a substrate and therefore cannot destroy. Methicillin, however, has its defects. Although adequate blood levels can be obtained its antibacterial activity against staphylococci is of the order of 1–4 μgm./ml. as compared with about 0.02 μgm./ml. for the activity of penicillin G against sensitive staphylococci. Methicillin is not effective by mouth and injections are sometimes very painful, though this difficulty can be overcome[35].

Phenoxypropyl penicillin (*PA* 248, Pfizer, Ltd.)[36] was reported to be slightly more active *in vitro* than phenethecillin against penicillinase-producing staphylococci. But it does not approach methicillin in activity against large inocula of these. Against other coccal infections it seems to have about the same activity as other oral penicillins such as penicillin V or phenethecillin.

Recently, new ground has been broken by the announcement that 6[D(–)α-aminophenylacetamido] penicillanic acid or α-aminobenzyl penicillin ('Penbritin')[37–40] has been synthesized at the Beecham Research Laboratories and tested experimentally

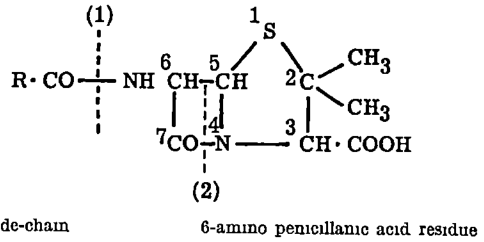

Fig 1 General formula of a penicillin (1) Site of action of penicillin amidase (splitting the amide linkage) (2) Site of action of penicillinase (giving rise to penicilloic acid)

and clinically It shows considerable activity against many organisms against which penicillin G is relatively ineffective, including many of the Gram-negative coliform organisms such as *E coli* itself, *Proteus*, *Salmonella*, *Shigella* and *H influenzae* It is thus the first broad-spectrum penicillin and is therefore of great practical and theoretical importance[41] Clinically it promises to be useful in the treatment of urinary infections and chronic bronchitis and in many gastro-intestinal infections, especially typhoid fever Its spectrum of activity is similar to that of the tetracyclines and chloramphenicol It has considerable activity against the cocci and other organisms naturally sensitive to penicillin G

The penicillins so far discussed have all shown sufficient promise to justify their commercial production for clinical use Two other substances should be mentioned here because of their great theoretical interest and importance 6-Aminopenicillanic acid itself, the penicillin nucleus, is the starting point for the synthesis of many new penicillins, either chemically or by means of amidases which occur in many species of micro-organisms Amidases can also hydrolyse penicillins into the free side-chain and 6-aminopenicillanic acid[42,43] This type of action is quite distinct from the opening of the β-lactam ring which occurs when 6-aminopenicillanic acid is acted on by penicillinase These two types of enzymic action are shown in Fig 1

Cephalosporin C [44] has a nucleus, 7-aminocephalosporanic acid, which consists of a β-lactam ring, fused, not with a thiazolidine ring as in 6-aminopenicillanic acid, but with a 6-membered sulphur-containing dihydrothiazine ring Cephalosporin C and related substances have some of the properties of penicillins Cephalosporin C itself like methicillin is very stable to staphylococcal penicillinase and is also a powerful inducer of the enzyme But its antibacterial activity is very low Although recently considerably more active derivatives of cephalosporin C have been obtained the activity is still less than that of penicillin G

Some of the main characteristics of these penicillins are summarized in Table 1

Different 'Functions' of Penicillin

There are at least seven 'functions' or activities of a penicillin to be considered—toxicity, activity in the presence of protein, acid-stability, production of hypersensitivity, stability to penicillinase, ability to induce penicillinase and finally antibacterial activity. To be of real clinical value, a penicillin must if possible be non-toxic, active in the presence of protein, capable of producing adequate levels in blood in therapeutic doses, and, if it is to be given by mouth, acid-stable The new commercially produced penicillins have all these properties—except methicillin, which is ineffective by mouth So far as is known, patients hypersensitive to one penicillin are likely to be hypersensitive to another, but more clinical and experimental evidence is needed It is not even certain how frequent hypersensitivity to the older penicillins really is Some reports have suggested that allergic reactions, many of them serious, are becoming more frequent[45] A recent survey[46], however, shows that of 35,496 patients attending clinics for penicillin injections only 255 (7 2 per 1,000) showed reactions, and only 9 patients showed moderate or severe 'anaphylactic' reactions But the frequency of reactions increased up to 66 per 1,000 in patients receiving large doses for several days

Antibacterial Activity, Penicillinase Stability and Induction of Penicillinase in Different Penicillins

The three functions of antibacterial activity, of stability to penicillinase and of capacity to induce penicillinase can to some extent be segregated in different penicillins[47] This segregation gives the facts on which some useful working hypotheses may be based It will be useful to start by comparing the antimicrobial activity of these different penicillins in terms of their stability to penicillinase (Table 1) With staphylococci sensitive to penicillin G it seemed at first as though the more easily a penicillin was split by penicillinase the greater was its antibacterial activity But the correlation no longer holds with α-aminobenzyl penicillin, which is much more easily hydrolysed by penicillinase than penicillin V or G, yet rather less effective against sensitive staphylococci With penicillinase-producing staphylococci, at first sight it seems that the more resistant it is to penicillinase the more effective will a penicillin be With large inocula this is true, but not with small Small, and sometimes even moderate, inocula of these are

Table 1

MAIN FEATURES OF DIFFERENT PENICILLINS

Structural Formula R =	Name	Antibacterial Activity Gram+ cocci	Penase+ staph	Gram neg rods	Hydrolysis by staphylococcal penicillinase	Induction of staphylococcal penicillinase
	Benzyl, G	+++	–	(±)	++	+
	Phenoxymethyl, V	+++	–	–	++	+
	Phenoxyethyl (phenethecillin, broxil, syncillin)	+++ –	(±)	–	++ –	+±
	Phenoxypropyl (PA 248)	+++ –	(±)	–	++ –	+±
	2 6 dimethoxyphenyl (methicillin, celbenin, staphcillin) (BRL 1241)	+	+	–	–	++
	α-aminobenzyl (BRL 1341)	++	–	+	+++	+
–	6-aminopenicillanic acid	(–)	(–)	(–)	(±)	(+±)

more sensitive to phenethecillin or phenoxypropylpenicillin than to either penicillin G or methicillin, despite the fact that both are slightly more stable than penicillin G and very much less stable than methicillin to staphylococcal penicillinase. A penicillin stable to one penicillinase is not necessarily stable to others. Methicillin is only slowly attacked by staphylococcal penicillinase but is more vulnerable to *B. cereus* penicillinase and probably to penicillinases from some strains of *Proteus*[48] (though it has not yet been proved whether destruction of methicillin by *Proteus* is due to an amidase or a penicillinase). The only highly active 'Gram-negative' penicillin so far available, α-aminobenzylpenicillin, is the most susceptible of all to staphylococcal penicillinase[47].

There is a closer correlation between the stability of a penicillin to penicillinase and its capacity to induce the enzyme in that species (see Table 1). With 6-aminopenicillanic acid itself both the rate of hydrolysis by staphylococcal and *B. cereus* penicillinase and its ability to induce enzyme formation seem to vary considerably with the conditions used. For example, Steinman's[49] figures do not agree with those of Batchelor *et al.*[11], who found that the *p*H for maximal speed of hydrolysis was different for 6-aminopenicillanic acid and penicillin G, and that at their respective *p*H optima both substrates were split at much the same rate. As regards inducing ability, it is necessary to distinguish between the concentration required for maximal or half-maximal induction and the total amount of enzyme finally formed. But while the relative 'efficiency' of 6-aminopenicillanic acid and penicillin G as inducers of penicillins is likely to depend greatly on the conditions used, for example, *p*H, evidence so far available[47,49] suggests that neither is as good an inducer as methicillin.

Structural Basis for the Activity of Different Penicillins

With several enzymes, notably succinic dehydrogenase[50–52] and cholinesterase[53], a good deal is known about the relation of molecular structure to specificity of action. Similarly, the new penicillins are already beginning to give a clearer picture of the relation between the different aspects of penicillin activity. Considering first the enzyme-substrate aspect, we may picture a penicillin molecule diagrammatically (Fig. 2) as having a number of specific groups which become anchored to complementary groups on the 'active patch' of the enzyme penicillinase. If the fit between the penicillin and the enzyme is good enough then carbon atom (7) is pulled away from nitrogen atom (4) (Fig. 1), the β-lactam ring is opened, the penicillin is hydrolysed, and another penicillin molecule takes its place in apposition to the active patch of the enzyme, and so the process continues. A penicillin resistant to penicillinase is one in which sufficiently close contact cannot be achieved for the sequence of reactions which result in the splitting of the β-lactam ring. This might be because other groups such as the two methoxy groups in methicillin cause steric hindrance, or, as in cephalosporin C, because the molecule is not quite of the right shape for the necessary contacts to be made with receptors on the enzyme surface all along its length. For induction, however, there may not be the need for 'multi-point' contact but only for 'anchoring' at a small number of key-points (*I* in Fig. 2). The immediate precursor of the penicillinase molecule or indeed perhaps the molecule itself may be regarded as having active groups on its peptide backbone corresponding to complementary groups on the penicillin molecule. One of these might be the C=O group at C (7), others may be at the ends of the penicillin molecule. In the uninduced enzyme the apposition between these complementary pairs of groups is inaccurate. The actual process of induction may consist of 'straining' the molecule of penicillinase (or enzyme-forming site)[54] so that now the corresponding groups on the enzyme and the penicillin can be anchored, perhaps by hydrogen bonds[52], perhaps in other ways. An inducer which is stable to penicillinase then would be one which can strain the enzyme molecule so that it is now capable of hydrolysing any penicillin which has the necessary groups on its molecule. But the penicillinase-stable inducer itself will not be hydrolysed because it lacks these or because other groups on its molecule prevent contact with the corresponding receptors on the enzyme molecule. The enzyme once induced will maintain its activity so long as it is presented with a penicillin—either with one which it can hydrolyse or with one which continues to maintain the enzyme in the induced state. Pollock[55] studied the capacity of different penicillins and penicillin derivatives to induce the formation of penicillinase in *B. cereus* and established some of the structural requirements for induction. The value of such comparisons will be greatly increased as new penicillins become available.

The interactions occurring at the specific site may be regarded then as involving two main steps. In the first, the inducer exerts on the pre-enzyme, on the enzyme-forming system, or on the actual enzyme the same forces that the substrate exerts on the enzyme (or the enzyme on the substrate). Thus both a substrate and inducer are, as it were, 'conditioned' for the next stage—the splitting of the β-lactam ring. But with an inducer which is not a substrate the actual splitting does not occur for the reasons already suggested.

It is less easy to construct a convincing model of the antibacterial activity of different penicillins. Cooper[56] has suggested that the process of attachment of penicillin to the receptor site in the penicillin-sensitive cell is associated with the opening of the β-lactam ring, in other words with a penicillinase-like reaction. It is not known whether the receptor with which the penicillin reacts is a precursor of the enzyme penicillinase, or the enzyme itself, or a 'penicillin-binding component' or enzyme-forming system which reacts with the penicillin molecule in such a way that either the penicillin destroys the cell or the cell destroys the penicillin[55,56]. Whichever of these alternative theories we adopt it seems clear that similar if not identical receptors are involved in penicillinase induction and activity and in the antibacterial action of penicillin. I have already suggested that for efficient hydrolysis of a penicillin to occur by means of the enzyme penicillinase there must be 'multi-point' contact all along the molecule with the corresponding active centres on the enzyme surface. Similar, though not identical, closeness of fit may be necessary for antibacterial action, and the type of antibacterial action may be determined by the closeness of fit at different sites. Two of these seem to be especially important—the 'amide' carbon and the first carbon beyond it on the side-chain.

Fig. 2 represents diagrammatically the ways in which these different properties of a penicillin may be related and suggests the following hypothesis The capacity to induce is a property of all penicillins and it depends partly on the length of the molecule When induction occurs the surface of the enzyme or the enzyme-forming system is strained so that it is brought into intimate contact with the two ends of the molecule and with carbon (7) in the β-lactam ring The induced enzyme can be regarded as being under some sort of tension, and it is only when it is brought into intimate contact in this way with these key-points that the rest of the molecule is able to exert its hydrolytic effect Fig 2(1*a*) shows the situation that may exist with benzyl penicillin when it is brought into apposition with an active penicillinase For maximal Gram-positive activity the area marked in the diagram must be brought into apposition with a cell 'receptor', which may be the same as a receptor on the enzyme surface, for maximal Gram-negative activity the area marked Gram-negative must be brought into apposition with the corresponding 'Gram-negative' area The penicillinase-stable methicillin can still induce, but splitting of the β-lactam ring is impossible (Fig 2(2)) There is still room for some Gram-positive activity with penicillins of this kind but the Gram-negative activity must necessarily be lost, in other words, the very steric hindrance which makes a penicillin of this kind resistant to penicillinase will make it ineffective against the Gram-negative organisms which have a receptor surface which must be brought into close contact with one of the side-chains attached to the carbon next to the aromatic ring This activity is greater when one of the hydrogens in penicillin G is replaced by NH_2 (Fig 2(1*b*)), which brings about close contact with the 'Gram-negative' site

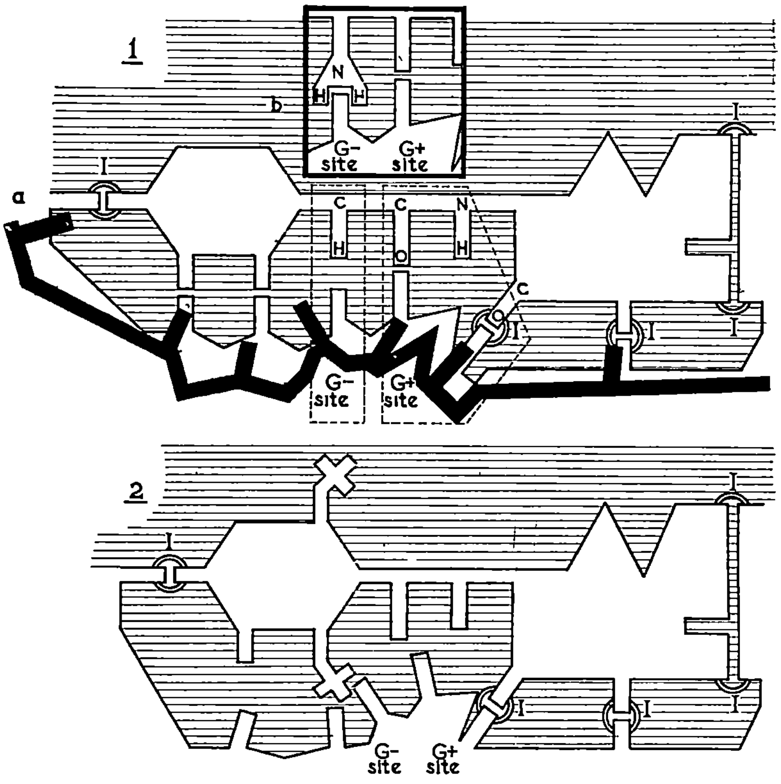

Fig 2

At the cellular level, there have been many theories about the site of the action of penicillin Many of the earlier observations can be explained in the light of recent evidence that penicillin interferes with the incorporation of amino-acids into the cell-wall and thus with the synthesis of cell-wall mucopeptide[57] Rogers and Jeljaszewicz[58] have shown that the order of effectiveness of different penicillins is the same for both antibacterial activity and interference with cell-wall mucopeptide synthesis

Resistance to Penicillin in Micro-organisms

With penicillin G clinically significant resistance is almost unknown except with the staphylococcus Other organisms such as hæmolytic streptococci, pneumococci, meningococci and others have remained fully sensitive to penicillin G In staphylococcal infections clinical failure is associated with the emergence of penicillinase-producing strains[59,60] These, though capable of destroying large quantities of penicillin when once the enzyme has been induced, are inherently sensitive to it and may be destroyed by it if they cannot produce penicillinase quickly enough On the other hand, in the laboratory it has proved easy to develop 'inherent' resistance of a non-penicillinase type in many different species of micro-organisms by serial sub-culture in gradually increasing concentrations of penicillin It is uncertain whether a similar non-penicillinase type of resistance is likely to be of clinical significance in any infections except perhaps for the gonococcus[61] It is also uncertain exactly how the penicillinase-producing types of staphylococci which are clinically so important actually arose It is doubtful whether there is any proved case of the emergence of penicillinase-producing staphylococci of the same phage type from an originally sensitive strain during the treatment of an individual patient with penicillin Thus penicillin shows the apparently paradoxical features of slow *development* of resistance and rapid *spread* of 'resistant', that is penicillinase-producing, strains by 'cross-infection'

It will therefore be particularly interesting to see what happens with new penicillins With methicillin a survey was carried out by Jevons at the Public Health Laboratory, Colindale[62] Of 4,430 strains from different regions only one showed increased resistance to methicillin So far it seems that methicillin-resistant mutants occur even more rarely than did penicillin G-resistant mutants in the early days of penicillin They have not so far been found to destroy methicillin In this respect they are rather more like the penicillin-resistant mutants produced by selection in the laboratory than naturally occurring penicillinase-producing strains Experiments we have carried out in our laboratory[63,64] have shown that staphylococci resistant to methicillin, whether naturally or by artificial selection in the laboratory, also show 'inherent' resistance to all other penicillins tested But with a mutant naturally resistant to about 25 µgm /ml of methicillin which showed 'inherent' resistance to penicillin G, further selection of mutants resistant to 1 000 µgm /ml of methicillin was not accompanied by any further increase in resistance to penicillin G More information is needed about the clinical importance and virulence of such mutants[65] and about cross-resistance in different penicillins

So far we have considered penicillin resistance almost entirely in staphylococci, but the new 'Gram-negative' penicillin, α-aminobenzyl penicillin, will raise some new problems Rolinson and Stevens[37] have pointed out that there is evidence for a penicillinase type of resistance in some strains of *E coli, Proteus vulgaris* and *A aerogenes* It is clear now that each new penicillin as it is produced creates special problems of its own Accurate information can be obtained only if careful records are collected in a number of different centres as a base-line for comparisons in the future

Conclusion

The isolation of 6-aminopenicillanic acid has already led to the discovery of penicillins with new properties and has given a new impetus to antibiotic therapy. The search for new antibiotics has become something more than an empirical screening of many groups of organisms for some new kind of antibiotic activity Deliberate and rational modifications to the penicillin molecule by the addition of specific side-chains have produced penicillins with different types of spectrum, and although the type of spectrum could not have been foretold from knowledge of molecular structure, once certain types of activity had been found, further modifications of the molecule could be made leading to improved activity of the kind desired There still remain groups of organisms untouched by any of the new penicillins, for example, mycobacteria, pseudomonads and viruses But the broad spectrum activity of a penicillin such as α-aminobenzyl penicillin raises some hopes that further modifications may produce other broad-spectrum penicillins, even perhaps some with antiviral activity. Quite apart from these practical results the isolation of 6-aminopenicillanic acid has opened up a fascinating field for research The specific activity of different penicillins has raised many new questions about the so-called penicillin type of antibacterial spectrum and about the nature of penicillin resistance, and at the same time it has helped to provide some of the answers, which may be of great value in relation not only to penicillin and other antibacterial drugs but also to the specificity of enzymes and their biosynthesis The diagram (Fig 2) represents an attempt to put into concrete form some of the conclusions which logically follow from the facts known at the present time It must inevitably be inaccurate in part and may even be regarded as a caricature of the facts If it does nothing more than arouse constructive criticism it will have served its purpose

TRANSFER OF STRATOSPHERIC FISSION PRODUCTS INTO THE TROPOSPHERE

By D H. PEIRSON

Health Physics Division, Atomic Energy Research Establishment, Harwell

MOST programmes of fall-out measurement are designed primarily to provide a regular inventory of the radioactivity from nuclear test explosions with the purpose of computing the radiological dose to human populations. In addition, the radioactive debris during its passage through the atmosphere serves as a valuable tracer of meteorological processes.

The significant parameters in this meteorological tracer experiment fall into two classes. Measurements are made of the concentration in air or in rain-water of (*a*) the long-lived fission products, as an index of the rate of fall-out, and of (*b*) the ratio of short-lived to long-lived fission products to give the 'age' of the debris, that is, the ratio of mixing between debris from recent and earlier test explosions. The mixing ratio is derived from comparison of the measured fission product ratio with that calculated for a fresh mixture. The data for several of these tracers is assembled in Table 1, using the yields from fission by 14-MeV neutrons of uranium-238 published by Cunninghame[1] and by Ford and Gilmore[2].

Table 1 FISSION PRODUCT DATA

Fission product	Half-life	Fission product ratio	Value of ratio at date of fission
Cæsium-137	30 years	Sr^{89}/Sr^{90}	185
Strontium-90	28 years	Zr^{95}/Cs^{137}	145
Cerium-144	285 days	Ce^{144}/Cs^{137}	~ 28
Zirconium-95	65 days		
Strontium-89	50 days		

The present discussion is concerned with the mixing between fission products from the 'polar' stratospheric injections at 75° N in October 1958 and those from earlier injections, in particular from 'equatorial' injections at 11° N about June 1958. Evidence relevant to the transfer of fission products from stratosphere to troposphere will be presented in three forms, describing the variation of the fall-out parameters with latitude, time and with altitude. This evidence is based on measurements made at Harwell, which are in substantial agreement with the results of work reported elsewhere, notably in the United States by Lockhart *et al*[3,4].

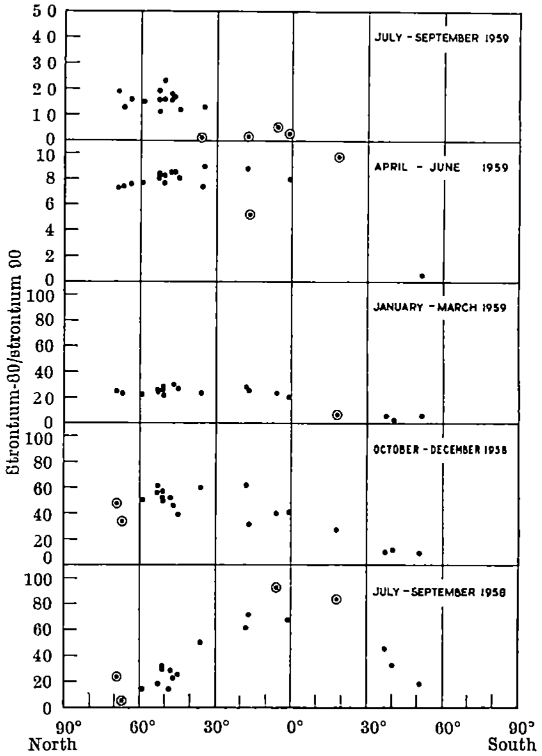

Fig 2 Ratio strontium-89/strontium-90 in rain-water v latitude, 1958–59
[O, Uncertain ratio due to low activities]

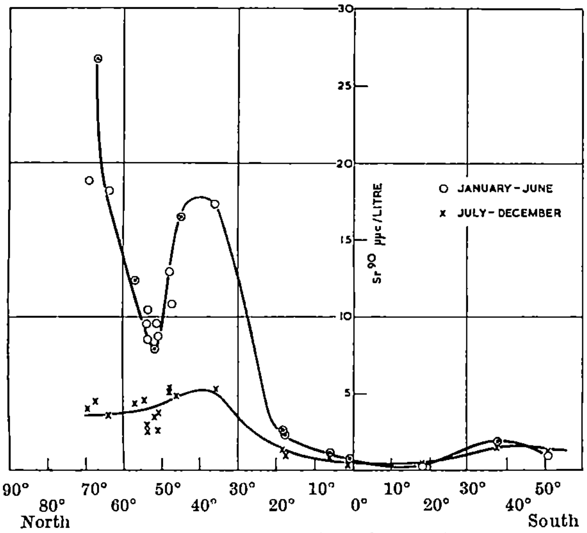

Fig 1 Mean strontium-90 content of rain-water, 1958–59

Variation with Latitude

The variation with latitude of the strontium-90 content of rain-water has been published by Crooks *et al*[5] for the period 1957–59. The main features of the variation, averaged over this period, is the rise to maximum values in the northern hemisphere in sub-tropical latitudes and above 60° N. The relative distribution varies with season as in Fig 1, which shows the mean concentrations of strontium-90 during the months January–June and July–December. Although the equatorial minimum is maintained throughout the year, the distribution above 30° N is comparatively uniform during the second half of the year.

A qualitative impression of the origin of the fission products during 1958–59 may be obtained from a study of the ratio strontium-89–strontium-90 in the same rain-water samples[6]. The variation of this ratio with latitude is shown in Fig. 2 for three-monthly periods from July 1958 to September 1959

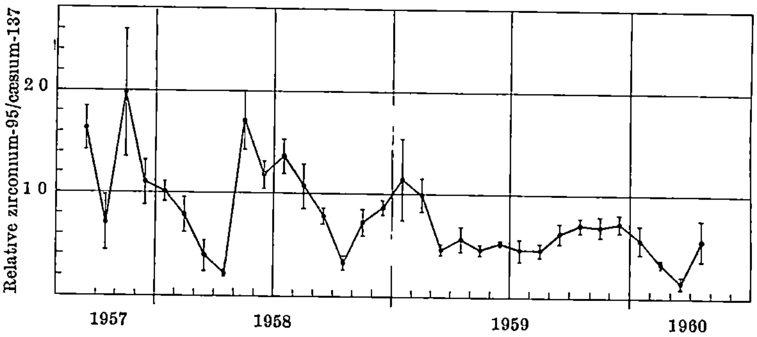

Fig 4 Ratio zirconium-95/cæsium-137 at 47,000 ft relative to 4,000 ft

From October 1958 the ratio strontium-89 – strontium-90, and hence the ratio of polar to equatorial debris, remained substantially independent of latitude in the northern hemisphere In the period July–September 1958, however, stratospheric fall-out from injections of fission products near the equator increased the ratio strontium-89–strontium-90 at low latitudes in both hemispheres

The content of strontium-89 in samples collected during this period is assigned to a stratospheric source because of the behaviour of the ratio[6] strontium-89–strontium-90 with time In the southern hemisphere, the ratio decreases from June 1958 according to radioactive decay The same observation can probably be applied to samples collected in the northern hemisphere, although in this case the record is confused by the arrival of fresh radioactivity from the test explosions of October 1958 If the strontium-89 were primarily tropospheric, it would disappear more rapidly, at a rate consistent with a tropospheric residence-time of 30 days[7]

Variation with Time

A periodic variation in fission product concentrations has been demonstrated[5,8] for samples taken from the troposphere and from rain-water in temperate latitudes of the northern hemisphere It was suggested by Stewart *et al* [9] that the observed periodicity is consistent with the meridional circulation in the stratosphere postulated by Brewer[10] to explain the low water content of the temperate stratosphere Recently, Goldsmith and Brown[11] have suggested that this ciculation is confined to the lower stratosphere. Martell[12] attributed the seasonal increase mainly to rapid fall-out from Russian stratospheric injections at high latitudes in the immediately preceding autumn and winter However, the spring maxima in 1955, 1960 and in 1961 followed autumns without stratospheric injection, and it can be shown that a peak remains in 1959 after the effect of stratospheric injections during the previous autumn has been subtracted[8] It is therefore probable that the seasonal cycle has a meteorological origin.

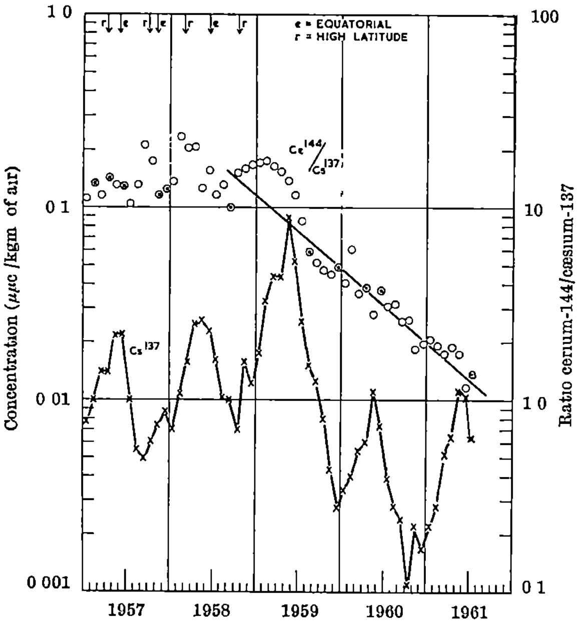

Fig. 3 Concentration of cæsium-137 and cerium-144 in air near ground-level at Chilton, Berkshire

In considering the variation with time of the isotope ratios, it has already been noted[8] that at ∼55° N the ratio zirconium-95–cæsium-137, in the case of tropospheric samples, and the ratio strontium-89–strontium-90 (rain-water samples) decreased according to radioactive decay, indicating uniform mixing of new and old debris, during the first six months of 1959. About June 1959 a discontinuity occurred in the isotope-ratio curves This effect is repeated in the record[6] of cerium-144–cæsium-137, shown in Fig 3, which extends the observations in air near ground-level at Chilton (Berkshire) until mid-1961. Owing to uncertainty in the fission yield data, there is not exact agreement in the proportions of polar and equatorial debris calculated from the various isotope ratios Nevertheless, using the cerium-144–cæsium-137 results, it is clear that whereas during January–June 1959 the proportion in these samples of long-lived debris produced by the Russian polar injections of October 1958 was about 70 per cent, for the period from mid-1959 until mid-1961 this proportion decreased to a value not greater than 20 per cent. This lower proportion was maintained through the subsequent spring peaks in 1960 and 1961, although the individual fission product activity varied by a factor of about five between spring and autumn

Variation with Altitude

This evidence is less general than the previous forms, in that the observations at the upper altitudes are restricted to the vicinity of the United Kingdom In January and February 1959 the ratio of polar to equatorial debris (measured by zirconium-95–cæsium-137) in the lower stratosphere at 47,000 ft and ∼55° N was similar[8] to that observed later in the troposphere. During the remainder of the year (Fig 4), the ratio zirconium-95–cæsium-137 was significantly higher in the troposphere than in the lower stratosphere[8], implying a higher proportion of polar debris in the troposphere

A Model of the Transfer Mechanism

The observations summarized above provide, in combination, a set of conditions that must be satisfied by any model of the transfer between stratosphere and troposphere One possible model will be described

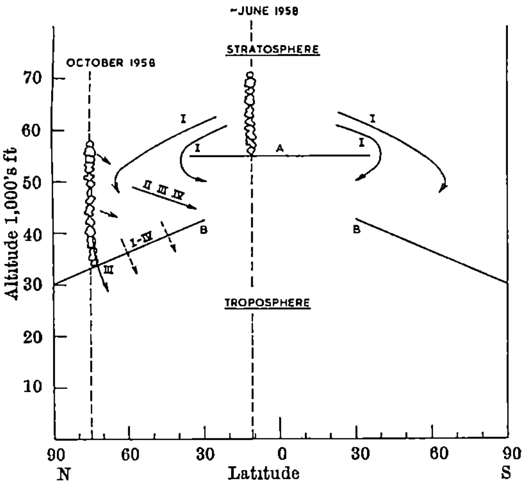

Fig 5 Transfer from stratosphere to troposphere

A, equatorial tropopause
B, temperate-polar tropopause
I, July–September 1958
II October–December 1958
III, January–March 1959
IV, April–June 1959

that attempts to explain the behaviour of the debris from the stratospheric injections in 1958 ('Hardtack') at 11° N about June and Russian at 75° N. during October Because the measurements of fission products are reduced to monthly average values, the model cannot account for short-term meteorological changes.

The movement of the debris is illustrated in Fig 5, which is a schematic diagram of the atmosphere showing stratosphere and troposphere separated by nominal tropopauses, equatorial and temperate-polar. Stratospheric fission products from the equatorial injection passed readily through the gap between equatorial and temperate tropopauses (Period I of Fig. 5) On the other hand, the polar debris appeared in the troposphere only after reasonably complete mixing with older debris the mode of entry during the autumn of 1958 (II) appears to be mainly through the same gap, but also possibly through the temperate-polar tropopause

It is only during the early months of 1959 (III) that a significant route appeared at high latitudes in the temperate-polar tropopause, in temporary competition with the gap between equatorial and temperate tropopauses Since the area of a band of latitude decreases with increasing latitude, it should be noted that the high concentrations occurring polewards of 60° N refer to only a small proportion of the total activity of the fission product The timing of this phenomenon is in accordance with the Brewer–Dobson circulation, in which the lower stratosphere is supplied in mid-winter by a subsidence of cold polar air. Despite the two possible paths of entry during this period, tropospheric samples were of such uniformity in the ratio of fission products (Fig 2) that the two streams must have arisen from a well-mixed source of equatorial and polar debris The mixing of debris must have occurred either in the lower stratosphere or in the troposphere If mixing occurred in the troposphere, under the influence of a tropospheric circulation system, then it is difficult to reconcile the uniform distribution of the ratio strontium-89–strontium-90 with the non-uniform distribution of strontium-90 (Figs 1 and 2) It is necessary, therefore, to postulate that mixing took place in the lower stratosphere to account for uniformity of the ratio of fission products, and that the distribution of individual fission products with latitude is probably controlled by the points of entry through the tropopauses, assisted by the tropospheric circulation system

In spring and early summer 1959 (IV), the exchange through the temperate-polar tropopause diminished, leaving the gap between equatorial and temperate tropopauses as the dominant path of entry. By this time the source of polar debris was largely exhausted and the supply to the troposphere contained a higher proportion of equatorial fission products

This new mixing ratio was maintained from mid-1959 through 1960 and into 1961 (Fig 3), apparently undisturbed by the Brewer–Dobson subsidence that would occur in the winters of these years This more recent evidence suggests that any residual polar debris (October 1958) was stored higher in the stratosphere with equatorial debris from 'Hardtack' (1958), and probably from earlier test explosions such as 'Redwing' (1956) and even 'Castle' (1954) The polar debris appeared as a small fraction of the well-mixed tropospheric samples collected during 1960 and 1961 This fraction, calculated from the ratio cerium-144–cæsium-137, is consistent with a date of origin lying between November 1957 and February 1958 A similar calculation made by Parker and Crookall[13] for samples collected during 1960 gave a mean date of origin in April–May 1958 The two sets of experimental ratios of fission products are in good agreement. the difference in estimated date is due to the assumption of different fission yields for the two isotopes

It was observed that during most of 1959 the proportion of polar debris sampled in the lower stratosphere over the United Kingdom was lower than in the troposphere It is difficult to fit this evidence into the scheme proposed in Fig. 5 Since it may represent a local anomaly, it is sufficient at present to note that in the latitudes of the United Kingdom the stratosphere and the troposphere maintained separate identities during this period This suggests that the two regions of the atmosphere are supplied from reservoirs of radioactive debris by separate routes and that there is little local mixing between them Alternatively, the difference in isotope ratio could be explained by a wash-out mechanism in the troposphere that favoured selective removal of older debris, or by selective filtering in the air-sampling apparatus From other evidence both these explanations are unlikely

Conclusion

The variations of certain fall-out parameters, namely, the concentration and ratio of fission products, have been summarized in relation to latitude, time and altitude These phenomena are influenced by the mechanism of transfer of fission products from the stratosphere into the troposphere

A speculative model of this mechanism has the main features that follow, based upon the behaviour of fission products injected into the stratosphere in the summer and autumn of 1958

Debris from the polar injection was well mixed with other debris before entry to the troposphere The tropospheric circulation system may contribute to the distribution pattern of the debris with latitude, although this appears to be controlled by the points of entry through the tropopauses

Well-mixed debris escaped in the early months of 1959 through the temperate-polar tropopause at latitudes greater than 60° N This escape was probably associated with subsidence of stratospheric air, according to Brewer and Dobson, and suggests a virtual disappearance of the troposphere at these latitudes

Most of the polar debris appeared in the troposphere during the first six months of 1959 A small residue from the polar injection may have lodged above the lower stratosphere This residue would have been brought down, together with older debris, during subsequent winter subsidences, and appeared as a well-mixed fraction of the fission product concentrations measured during 1960 and 1961

The proportion of polar debris in the lower stratosphere above the United Kingdom in 1959 was lower than in the troposphere This effect may be restricted in extent and have no great significance in a global model

ELECTRICAL POWER DEVELOPMENT

THE annual meeting in June of the British Electrical Power Convention was held, as has been customary in recent years, at Eastbourne, under the presidency of Sir John Pickles, chairman of the South of Scotland Electricity Board In his presidential address he gave emphasis to the theme of the Convention—"Electricity in the Prosperity and Welfare of the Nation" The address was in the form of a review and prospect of the electricity supply industry in Britain from A D 1880 to 2000

Sir John considered that there would be a doubling of consumption in the ten years to 1970 and that this rate of increase would be maintained, with a further doubling by 1980, or 1985 at the latest This implies an increase in the country's installed generating plant capacity, at present 32,000 MW , up to 100,000 MW , the greater part of this probably being nuclear There would probably be 1000-MW single generating sets, and their operation, together with that of their boilers, would be controlled by computers In transmission a 750-kV system seems not unlikely Sir John concluded by referring to the possibilities of direct conversion of heat to electricity without the intervention of a steam cycle, attention being focused on thermionic, thermo-electric and magnetohydrodynamic generation The latter, comprising direct generation by the passage of hot gas through a magnetic field, is the most promising Nuclear fission may well prove highly suitable as a heat source

The second speaker, Sir Christopher Hinton, chairman of the Central Electricity Generating Board, described the British electricity distribution system from the inception of the 132-kV grid, which was intended for the transfer of energy between the large self-contained areas under conditions of difficulty or emergency Much expert opinion at that time held that it would be impossible to interconnect the complete system without leading, under conditions of rapidly changing demand, to major power flows which could not safely be handled Notwithstanding this, the London control engineers interconnected all the separate areas by means of the grid "to see what would happen" The interconnected system—the largest in the world controlled from one centre—has worked ever since Various extensions and reinforcing interconnexions have been added, giving additional security and flexibility

Work carried out at the formation of the British Electricity Authority and the area boards under the Electricity Act of 1947 showed a sound case for siting new generating plant near coalfields This implied the provision of a higher voltage transmission system superimposed on the existing grid A transmission voltage of 275 kV was selected, this being the next higher International Electrotechnical Commission standard It was considered that this voltage is not so high as to lead to possible insulation difficulties in the atmosphere of Great Britain Tower clearances, however, allow for up-rating in the future to 380 kV —the next higher level—when insulation problems have been solved So the 275-kV super grid system in Britain was formed, developing mainly into ring mains of double-circuit lines connecting large-capacity generating stations and substations with transformation, usually to 132 kV Transmission is by no means the junior partner of generation it is perhaps dominant, for without the present highly developed transmission system—planned with foresight and wisdom by the old Central Electricity Board and those associated with it—the modern 2000-MW generating station would be impracticable

Sir Christopher Hinton reported that the maximum demand on the system so far was 24,449 MW , on December 13, 1960, and he suggested that this might be trebled in fifteen to twenty years time The heaviest concentration of power stations would be in the central coalfields, with others in North Wales, the Severn Estuary, the Bristol Channel, the central south coast, the Thames Estuary, south-east Kent and the East Anglian coasts He showed a map giving the distribution of power expected in the mid-1970's, when the maximum demand is likely to be 70,000 MW and the projected 400-kV supergrid fully operative Nuclear generation should by then account for 30 per cent of the total consumption, indigenous fuel and oil consumption being roughly doubled The movement of coal long distances by rail should virtually have ceased by this time, and sea-borne supplies reduced to roughly half their present value As the load grows beyond 70,000 MW in the years after 1975, it is possible that a 700-kV. 'large mesh' network will be superimposed on the 400/132-kV system

Sir Christopher continued by explaining the many factors not susceptible of control by the area boards which make accurate forecasting of future needs very difficult. He referred to shifts of population, town planning legislation and Government decisions on residential and industrial development. Forecasting is simple on a national scale and difficult on a local scale.

About 40 per cent of the area of England and Wales is subject to restriction of some sort or other on the ground of amenity; but opposition to the construction of transmission lines and equipment is sometimes just as severe in industrial towns. Yet a transmission system of the present type is vital to British industry and essential if the very large stations (small in number and of high efficiency) are to be built. Although the public would not tolerate the ever-increasing extension of the network to a stage rightly described as a 'wirescape', underground cables for all additions to the network are out of the question on ground of cost. (A figure of about £100 million a year would be involved, representing 6*d*. on the standard rate of income tax, or 20 per cent on the bulk tariff.) The solution, perhaps a compromise, is to place underground the lower-cost distribution systems and leave the very high-voltage transmission system in the form of lines on towers. The latter must be accepted as canals, railways and motorways are, but the design of the structures must be the most graceful that can be devised and their routing must be most carefully planned. Sir William Holford set out in a paper to the Royal Society of Arts valuable rules relating to the siting of transmission lines. Switching stations, too, are now being most carefully considered. Sir Christopher Hinton concluded by emphasizing that the problem of visual amenity is one of the greatest facing the industry.

Mr. R. R. B. Brown, chairman of the Southern Electricity Board, presented a paper entitled "Some Aspects of Efficiency and Economy in Distribution". He reported that the national investment in distribution assets stands at more than £1,000 million, and additional expenditure at the rate of about £100 million annually is necessary to meet the expanding needs of the nation. Mr. Brown showed ways in which investment economies have been and will be achieved; and he dealt with tariff structures devised to encourage the full and efficient use of distribution systems. An interesting point made in connexion with standardization was that less than a hundred thousand consumers out of some 16 million now receive direct current supplies; consumers served by non-standard alternating current systems number about 1,500,000.

A paper by Dr. A. E. Grauer, chairman and president of the British Columbia Electric Co., Ltd., was on "The Electrical Power Industry in Canada". Canada, with a population of only 18 millions, is one of the world's largest producers (and consumers) of electric power. On a total output basis, she is behind the United States and the U.S.S.R., but on a par with the United Kingdom. Canada is second only to Norway on a *per capita* basis. Much of Canada's power is, of course, hydro-electric, and in Quebec power-rates are less than a third of the Canadian-American average. In Ontario and Manitoba they are about half the average in the United States. Canada's impressive power growth has been predominantly due to important power-consuming industries, smelting aluminium, refining copper, nickel and titanium and manufacturing inorganic chemicals. This growth has helped to open up new territory and expand Canada's world trade.

It is interesting that primary jurisdiction over natural resources, including water, was given to the Provincial Governments rather than to the Federal Government, and this, together with the huge areas of most of the provinces, has resulted in electrical utilities each essentially operating within one province. There are no electrical utilities which are national in scope.

Much of Canada's land mass (in area almost equal to China, which is itself second only to the U.S.S.R.) is virtually uninhabited, and population has tended to concentrate in a few areas strung mostly along the southern border and separated from each other by hundreds of miles. Almost a third of the population lives in the southern tip of Ontario. Nearly ten million Canadians occupy an area less than that of the United Kingdom.

The manner in which the electric power industry is organized varies a great deal from one province to another. In some provinces there is practically no private ownership, in others practically no public ownership; in others there is a mixture of both. The sizes of the utilities differ considerably, from Ontario Hydro, with a total capacity in excess of 6,000 MW, to quite small undertakings. Publicly owned utilities are usually run by a small commission reporting directly to the Cabinet. Investor-owned utilities operate under a Public Utilities Act administered by a Commission appointed by the Provincial Government. Fair rates are set by the Commission.

Canadians used, in 1959, 4,300 units of electrical energy per residential customer as compared with 3,700 units in the United States and about 2,000 units in the United Kingdom. One possible reason is that about 80 per cent of Canadians live in single or duplex dwellings. Also, the straight block-rate, with no demand charge, is almost universal, except for house heating. Off-peak tariffs are not used in Canada; industry works mainly on a three-shift system. It is interesting that Dr. Grauer's Company estimates each customer's bill for a ten-month period, sends him a bill each month for a tenth of this amount, and then balances the books by a payment of the difference either way at the end of the period.

Regarding rate of growth of electrical consumption, a relatively low figure might be expected from an already high consumption. Estimates point to an average figure of more than 6 per cent per annum and require the construction of more than 50,000 MW of new capacity by 1980. It is expected that most of the money to finance this will continue to be raised in Canada. This does not necessarily apply to the Peace River (British Columbia) and Hamilton Falls (Labrador) developments. It would appear that here are opportunities for British investment in Canada.

Canada's commercial water-power potential is considered by Dr. Grauer to be 70,000–80,000 MW; the present installed turbine capacity is about 20,000 MW. The largest undeveloped hydro resources are in Quebec and British Columbia, with Newfoundland and Manitoba following. Canada and the United States have, of course, signed a treaty respecting the Columbia River and construction is expected to start in 1962, with output of electrical energy by 1966.

Dr. Grauer made some interesting remarks concerning the development of thermal generation. The latter is necessary in some main industrial centres because of the existing full development of nearby water resources and because of the increasing costs of more remote hydro development. Steam-electric generation near the load centres is tending to cost less, improvements in design offsetting inflation. The margin of cost between hydro and thermal generation is thus narrowing steadily. A large coal-burning base load plant on the waterfront of Toronto can deliver electric power at a cost only about fifty per cent higher than can the new hydro-installations at Niagara and on the St. Lawrence Seaway. (About 1920 thermal electric power cost three to five times as much as hydro-electric power in southern Ontario.) Provinces using thermal generation in the future will be Alberta, Saskatchewan (with cheap fossil fuels and natural gas), Ontario (with almost fully developed hydro-resources she is importing coal from the United States) and British Columbia (with cheap residual oil and natural gas). Gas turbine plants are being built in sizes from 2,000 to 25 000 kW., but are unlikely to be used extensively because of their heavy fuel consumption compared with that of large steam turbines.

Canada has several large research reactors in operation, being particularly interested in heavy-water moderated systems fuelled by natural uranium. (Heavy water has been produced in Canada and could be again. Uranium is found in abundance.) The large conventional resources still available in Canada make it likely that nuclear power will first be commercially developed elsewhere, with southern Ontario as an exception to that statement in view of its present need to import coal from the United States.

Dr. Grauer made some useful comments on long-distance transmission and the possibilities of a national power grid. Most transmission in Canada is at 230 kV., with 360 kV. being introduced in recent years. Distances of transmission have not exceeded about 250 miles, but much longer distances are in prospect. Ontario Hydro is planning 500 miles of 460-kV. line. The Peace River proposal envisages 600 miles at 500-600 kV., and tests are under way, both in Canada and the United States. Present thinking in the U.S.S.R. is that distances less than 600-800 miles are more efficiently met with alternating current, while for distances greater than this, direct current is more efficient. Canada's distances are similar to those in the U.S.S.R. However, potential developments are so placed relative to population centres that few distances of greater than 600 miles are contemplated. Three large potential hydro-situations in the far north are about a thousand miles from the chief market and their development will presumably await the d.c. transmission of the future. Dr. Grauer believes that a national power grid, for a number of reasons (not the least being that natural gas in large pipe-lines can be transported for less than one-third the cost of transporting electrical energy over the highest voltage lines) is more likely to evolve over a period of time from regional systems stronger and more highly developed than exist to-day.

The final paper of the conference, presented by Mr. S. F. Steward, director of the British Electrical and Allied Manufacturers' Association, was entitled "British Electrical Manufacture in the National Economy". The British Electrical and Allied Manufacturers' Association, the trade association of the electrical industry in Britain, is this year celebrating the fiftieth anniversary of its foundation. The main aim in establishing the new trade association in 1911 was "to foster some order and regulation in the trading of its constituent firms". It is interesting to note that within a year or two of the Association's foundation the annual report invited "the earnest attention of members to industrial and scientific research as one of the bedrocks of commercial supremacy".

Early attention was given to the legal conditions applicable to contracts for heavy plant, and, in association with the Institution of Electrical Engineers, model general conditions were drawn up which, when published in 1914, became the first standard text of its kind in the world. Technical and commercial co-operation, publicity and export promotion were early recognized as main functions of a trade association. Standards were issued as early as 1913 for the use of member firms, priority being given to the standardization of electrical machinery.

Mr. Steward reviewed in considerable detail the development of the electrical industry throughout five decades, emphasizing the extent to which electrical manufacture has become a key industry. About ten per cent of the total United Kingdom export of manufactured goods represents electrical equipment. The total number of employees in the industry is nearly 800,000, 28 per cent of this number being engaged in the manufacture of electrical machinery and 38 per cent on electronics and telecommunications equipment. Electrical manufacture is the largest industrial employer of scientists and technicians. In 1959 the industry employed 13,380 qualified scientists and engineers.

The drawing up of conditions of contract and contributions towards the establishment and maintenance of standards continue to be important activities of the Association. Of increasing importance is the collection and dissemination of statistics and information, the study of trends and of overseas competition. "A trade association must be a realistic partnership of competing concerns, not with the purpose of restricting competition but to secure the best use of an industry's resources and to provide the basis for the full development of initiative and enterprise".

A. J. ELLISON

OBITUARIES

Prof. M. L. Anderson

THE death of Prof. M. L. Anderson, of the chair of forestry in the University of Edinburgh, occurred on September 6 at Bristol, while he and Mrs. Anderson were on a visit to their married daughter.

Mark Louden Anderson was born on April 16, 1895, at Kinneff in Kincardineshire. He had the misfortune to lose both parents when he was only eleven years old. He entered the forestry course at the University of Edinburgh in 1912, but saw service throughout the First World War, first in the Argyll and Sutherland Highlanders and the Black Watch, and then in the Machine Gun Corps, winning the Military Cross in 1918. Returning to Edinburgh, he graduated B.Sc. (Forestry) in 1919, and five years later was awarded the D Sc degree for a thesis on tree form and volume studies

Prof Anderson was appointed to the Forestry Commission and as a research officer he had much to do with early experiments in planting on peat, provenance of species trials and the selection and measurement of sample plots His work was conducted with that depth of vision so necessary in practical research It was unfortunate that he had to give up this particular work when he did, but Eire gained his services and there he eventually became director of forestry This was followed by five years on the staff of the Department of Forestry, University of Oxford It was then his intention to take up a post offered by the Australian Forest Service, but instead he returned to the University of Edinburgh to be professor of forestry, a post which he occupied with distinction for ten years

Prof Anderson was an enthusiastic forester who showed his keenness in a variety of ways He enjoyed being in the forest, and he regretted when ill-health prevented him from visiting again the Continental forests, where he admired the practice of good sylviculture and sound management At any time he would discuss forestry matters and even provoke controversy for the fun of enjoying the outcome As a teacher, Prof Anderson was never verbose His great knowledge was readily available to the keen forester, no matter what the latter's rank was He believed that a good forester should have a proper basic knowledge and know how to observe. He had a wonderful gift for languages, most of which were self-taught, and he tried by his numerous translations from French, German, Danish, Norwegian, Swedish, Finnish and Russian books and papers to bring important works of Continental foresters to the English-speaking world Knuchel's *Planning and Control in the Managed Forest*, Kostler's *Silviculture*, Larsen's *Tree Genetics*, Petrini's *Forest Economics* and Tamm's *Northern Coniferous Forest Soils* are some of the larger translations Prof Anderson's *The Selection of Tree Species* is a very valuable guide for the British forester and it is now in its second edition Not long before he died, Prof Anderson completed the manuscript of his monumental work, *A History of Scottish Forestry*—the product of some thirty years of painstaking research It is to be hoped that financial difficulties will be overcome to allow this encyclopædic work to be published

Another aspect of Prof Anderson's keenness to stimulate an interest in forestry and to try to raise its general standard was the zeal and time he gave to forestry societies He was an ardent member of the Royal Scottish Forestry Society and recently its honorary secretary and the creator of its Silvicultural Group, a founder member of the Society of Foresters of Great Britain and also of the Forestry Society in Eire He was also a regular contributor to *Nature*

But forestry did not occupy all Prof Anderson's very full life He found great delight in transcribing old Scots records, and in this he took infinite care to obtain accurate results from folios which, at times, were rather difficult to decipher As a result of this work he was a regular contributor to the *Dictionary of the Older Scottish Tongue* His *Proverbs in Scots* were published in 1957, another example of painstaking work on a manuscript dating from the first quarter of the seventeenth century

Prof Anderson will be remembered as a great forester, an ardent Scot, a man respected for his integrity, his capacity for hard work, his willingness to help others, his friendliness and his great determination

Prof Anderson leaves a wife, two sons and a daughter, to whom our sympathy is extended

C J TAYLOR

Dr. W. A. MacFarlane, C B E.

THE sudden death on August 19 of Dr W A MacFarlane, managing director of the National Industrial Fuel Efficiency Service and president of the Institute of Fuel, at the age of fifty-three, came as a severe shock to his many friends and is a grievous loss to fuel technology in Great Britain

Although Angus MacFarlane was by training, and in his early work, a 'pure' chemist, the major part of his varied life was concerned with the efficient use of fuel After a brilliant career at Oxford, where he was a student of Sir Harold Hartley at Balliol, he spent two years at the University of California as a Commonwealth Fund Fellow carrying out research in physical chemistry for which he was awarded the degree of Ph D

On his return to Britain in 1934, after eight years in academic life, he joined the staff of the Fuel Research Station of the Department of Scientific and Industrial Research and thus first came into contact with fuel technology During the four years at East Greenwich his main contribution was the initiation of the Department's work on the Fischer–Tropsch process, which was destined to become one of the major research programmes of the Fuel Research Board, and to continue for a total period of some twenty-five years In 1938 MacFarlane left the Fuel Research Station to become senior research chemist to the London, Midland and Scottish Railway Co at the invitation of Sir Harold Hartley, then vice-president of the Company This move naturally led him into wider fields, but he was soon to return to fuel, for in 1941, after the formation of the Ministry of Fuel and Power, he was appointed the first director of fuel efficiency In this position he made an important contribution to the War effort by ensuring that every ton of coal was directed where it was most needed and used to the best advantage

After seven years at the Ministry, MacFarlane was appointed to the British Embassy at Washington as director of the United Kingdom Scientific Mission and attaché for scientific questions During his six years in Washington he did a great deal to foster and cement Anglo-American friendship and co-operation in the scientific sphere and there must be very many who, like myself, remember with gratitude the efficient help and warm hospitality he always extended to British scientists visiting the United States

In view of his earlier work at the Ministry, the selection of MacFarlane as director of the National Industrial Fuel Efficiency Service on its formation in 1954 was an obvious one, and the undoubted success of this organization in conserving fuel and reducing costs to the fuel user offers testimony to his efficient management His services to the nation were recognized when he was made a C B E in 1958, and his election to the presidency of the Institute of Fuel in 1960 is evidence of the high esteem in which he was held by his fellow fuel technologists

MacFarlane combined a sound scientific knowledge with an ability to appreciate clearly and rapidly the practical and economic aspects of a problem He had the gift of inspiring loyalty and affection in those working under him, and his intellectual gifts and genial personality won for him a very wide circle of friends by whom he will be sadly missed

He leaves a widow and four children

C C Hall

Mr. H. V. Griffiths, M.B.E

The sudden death of H V Griffiths on June 28, at the age of fifty-nine, came as a shock to his many friends and colleagues

As engineer-in-charge of the British Broadcasting Corporation's Receiving and Measuring Station at Tatsfield, he was widely known both in Britain and overseas as an authority on radio reception, propagation and frequency measurement He represented the B B C on a number of technical committees concerned with these subjects, about which he has written from time to time in *Nature* and other journals

Like many of his colleagues in the early days of radio, Griffiths started his career as a ship's radio operator, but his interest was in the technical, rather than the operational, aspects of his work, and it was not long before he entered the engineering field He joined the B B C in 1924 as an assistant maintenance engineer and later became a member of a team of engineers to work on the first short-wave broadcast transmitter used at Chelmsford by the B B C He also co-operated with Marconi engineers in the study of diversity reception on short waves

He was appointed engineer-in-charge at the Tatsfield Receiving and Measuring Station in 1933 and over the years he built up for Tatsfield a reputation for accuracy and reliability which has made the Station a world-wide name in radio His work was recognized when he was made M B E in 1958

Among his many other interests was astronomy He was a Fellow of the Royal Astronomical Society and was keenly interested in man-made satellites and their future possibilities in the field of world-wide radio communication He took an active part in monitoring the transmissions from the first *Sputnik*

H. V. Griffiths will be greatly missed by his many friends and colleagues, who will remember him not only for his expert knowledge, which he was always ready to pass on to others, but also for his sincerity and kindly patience and, above all, his enthusiasm for his work

L W. Turner

NEWS and VIEWS

Iodine-131 in Milk in Britain

The first results of an investigation of iodine-131 in milk, which has been in progress at the Agricultural Research Council Radiobiological Laboratory since weapons tests were resumed by the U S S R , were released on October 24 simultaneously with a general statement by the Medical Research Council (see *Nature*, November 4, p 400) A further statement from the Agricultural Research Council (dated November 1) summarizes more recent measurements Milk from twenty depots in central and southern England, Wales, Scotland and Northern Ireland is now being collected daily and examined for levels of iodine-131. This represents a considerable expansion of the sampling which has been carried out during the past six weeks at eight sites in different regions (see Table 1) These measurements enable the general trend throughout the United Kingdom to be assessed

Table 1 Levels of Iodine-131 in Milk produced at Eight Sites in Different Parts of the United Kingdom

Week commencing	$\mu\mu c$ Iodine-131/litre
September 16, 1961	85
September 24, 1961	109
October 1, 1961	138
October 8, 1961	150
October 15, 1961	114
October 22, 1961	158
Mean for six weeks (September 16–October 28)	126

Information on regional differences of iodine-131 is now obtained each week by analysing samples collected from more than 200 depots which handle more than 40 per cent of the total milk produced throughout the United Kingdom The samples are combined in proportion to the quantity of milk handled by the depots from which they are obtained so that the average level throughout a zone can be ascertained The present results are summarized in Table 2

Table 2 Levels of Iodine-131 in Milk produced throughout the United Kingdom

Mean results for samples collected on October 2, 16 and 23, 1961

Zone	$\mu\mu c$ Iodine-131/litre
1 Northern England	111
2 North-West England	100
3 East and East Midland	82
4 West Midland	106
5. Wales	174
6 South and South-East England	99
7 Mid-Western England	96
8 Far Western England	143
9 Scotland	178
10 Northern Ireland	161
Country-wide mean weighted for production	121

The country-wide mean of 126 μμc per litre for the six weeks ending October 28, which is shown in Table 1, represents about one-eighth of the total quantity of iodine-131 which would give rise to the annual average of 130 μμc per litre specified by the Medical Research Council The results in Table 2 show that, on a regional as well as a national basis, the iodine-131 which has hitherto entered milk represents but a small fraction of that which would give rise to the level specified by the Medical Research Council Further statements will be released at intervals until the levels of iodine-131 in milk have decreased appreciably

Theoretical Physics in the University of Sussex : Prof R. J Blin-Stoyle

Dr R J Blin-Stoyle has been appointed to the chair of theoretical physics in the new University of Sussex He attended Alderman Newton's Boys' School in Leicester, and received a senior scholarship at Wadham College, Oxford, in 1943, but before taking this up in 1946 was commissioned into the Royal Signals and served as lecturer in the College of Radio Communications at Mhow, Central India He received a B A (1949), D Phil (1951) and, during 1951–53, held a Pressed Steel Fellowship at Oxford. After a year as lecturer in mathematical physics in the University of Birmingham he took up his present post at Oxford as senior research officer in physics Since 1956 he has also been a Fellow and lecturer at Wadham College During 1959–60 he served as visiting professor of physics at the Massachusetts Institute of Technology and the University of California

Prof Blin-Stoyle is widely recognized as one of the ablest young theoretical nuclear physicists He has made valuable contributions to the theory of nuclear structure, with special emphasis on nuclear moments and β-decay His main object in this work is to use the nuclear properties to learn about more fundamental things. such as the possible charge dependence or parity non-conservation of nuclear forces, and the nature of weak interactions He has also been concerned with the theory of quantum fields and reactions of polarized nuclei He is much appreciated as a tutor and lecturer as well as for his research work and, although his departure will be sadly felt in Oxford, he should have greater possibilities at Sussex for implementation of his progressive ideas on the teaching of physicists His appointment promises much for the future development of physics at the new university.

Engineering Group of the United Kingdom Atomic Energy Authority

Mr. J B W. Cunningham

Mr James Bernard William Cunningham, who resigns as managing director of the Engineering Group of the U K Atomic Energy Authority as from January 20, 1962, was born in Middlesbrough, Yorks, on December 9, 1911 During 1928–39 he served as an apprentice with Cochrane and Co, Ltd, Middlesbrough, and Stanton Ironworks Co, Ltd, Middlesbrough, rising to works manager. During 1939–44 he was assistant works manager at Dewrance and Co, Ltd, London, and during 1944–47 was works manager at Pegsons, Ltd., Coalville Mr Cunningham then joined the Department of Atomic Energy of the Ministry of Supply at Risley, Lancs, as senior engineer (supply) In 1948 he became assistant chief engineer (design) and then was promoted to deputy chief engineer (design) in 1950, and chief engineer (design) in 1953 He continued to hold this post on the formation of the U K Atomic Energy Authority a year later and in 1956 was appointed deputy director (reactors) and in 1957 deputy director (industrial power) In the following year he became director of industrial power, and in 1959, on the division of the Industrial Group, Mr Cunningham became deputy managing director (technical) of the Production Group He was appointed to his present post in April this year.

Mr H V. Disney, C.B E.

Mr Harold Vernon Disney, who is to succeed Mr J B W. Cunningham as managing director of the Engineering Group of the U K Atomic Energy Authority, was born in Ruddington, Notts, on July 2, 1907 He was educated at Ilkeston and at University College, Nottingham After apprenticeship with G R Turner, Langley Mill, Notts, Mr. Disney went as a designer to International Combustion, Derby, in 1931 He joined Imperial Chemical Industries (Alkali), Ltd, Northwich, in 1935 as a design engineer on chemical plant projects In 1940 he was seconded by Imperial Chemical Industries for special duties on the construction of Ministry of Supply propellent and filling factories, and in 1944 became deputy director (filling factories supply) Mr Disney was a member of the original team which started the Department of Atomic Energy at Risley in February 1946 and was appointed chief engineer, services and supply, in 1947. In 1950 he became chief design engineer for the diffusion plant at Capenhurst, and in 1957 was promoted to deputy director (defence plants) at the U K Atomic Energy Authority He was appointed director of engineering of the Industrial Group in May 1958, becoming director of engineering of the Development and Engineering Group in July 1959 and deputy managing director of the Engineering Group in 1961 As from November 1, and until he takes over full responsibilities, he will be managing director (designate) of the Group.

Royal Society of Edinburgh : Officers for 1961–62

At the annual statutory meeting of the Royal Society of Edinburgh, held on October 24, the following officers and members of Council were elected *President*, Prof E L Hirst, *Vice-Presidents*, Dr T R. Bolam, Dr. Douglas Guthrie, Dr. A W Greenwood, Prof R A Rankin, Dr C. E Lucas, Prof J A Macdonald, *General Secretary*, Prof Norman Feather; *Secretaries to Ordinary Meetings*, Dr Mowbray Ritchie, Prof A E Ritchie, *Treasurer*, Dr J. R Peddie, *Curator of Library and Museum*, Dr. R Schlapp, *Members of Council*, Prof H A Bruck, Dr. H R Fletcher, Prof. G L Montgomery, Prof. W. L Weipers, Prof. J H Burnett, Prof C F. Davidson, Prof D. C Pack, Dr A. B Stewart, Prof Jack Allen, Dr S. C Curran, Dr. G H Mitchell, Dr Magnus Pyke.

Jubilee of the Atomic Nucleus

There have been speculations on the nature of atoms since the days of the ancient Greeks, but the first firm foundation on which modern ideas are built was the nuclear theory put forward by Rutherford in Manchester in 1911. Jubilee celebrations and an international conference were held in Manchester recently, and now the Science Museum has set up a small group of exhibits to illustrate various theories of atomic structure and Rutherford's great contribution The exhibits are on view in the Atomic Physics Section of the Museum They include a group of models of atoms as visualized by J J Thomson before Rutherford's theory, a further group illustrating Rutherford–Bohr atoms; several historic photographs relating to Rutherford's great Manchester period of research, and a working mechanical model illustrating how the observed scattering of α-rays by heavy atoms led him to the inescapable conclusion that the atom must have a small 'hard core' (which is now known as the nucleus) This nucleus itself is now being investigated with all the powerful and elaborate apparatus of modern physics and engineering The Science Museum exhibit makes no attempt to illustrate the many practical applications of our knowledge of the structure of the atom, as these will be dealt with in a full-scale special exhibition, "Atoms at Work," which will be staged in the Museum by the United Kingdom Atomic Energy Authority in March 1962

Centenary of Plastics 1862–1962

A joint committee of the Plastics Institute and the British Plastics Federation has been set up to organize a number of events in connexion with a

Centenary of Plastics 1862–1962 It was at the International Exhibition in London in 1862 that Alexander Parkes showed for the first time to the public "a new material and manufacture which from its valuable properties had induced the inventor to patent the discovery in England and France and to devote his attention for the last 10 years to the development of the capabilities and application of this beautiful substance to the Arts" In the case shown at the Exhibition were a few illustrations of the numerous purposes for which, according to Parkes, 'Parkesine' might be applied These included medallions, salvers, hollow ware, tubes, buttons, combs, knife handles, pierced and fret work, inlaid work, bookbinding, card cases, boxes, pens, penholders, etc. Parkes received a prize medal for his exhibit 'Parkesine' contained no camphor, an indispensable component of the later material celluloid, and while Parkes mentioned camphor in his patent of 1865 he did not appreciate its unique properties There can be no doubt, however, that 1862 saw for the first time the material which led directly to the modern form of celluloid The programme to be organized by the Joint Committee will include open days in firms in the plastics industry and special meetings and lectures throughout the centenary year (1962–63), culminating in the International Plastics Exhibition to be held at Olympia during June 12–22. 1963

Personnel Management Salaries

DURING the summer of 1956 the Institute of Personnel Management carried out a survey of salaries paid to members. This was undertaken because the Institute had been frequently asked by individual members, and by companies filling vacancies, about salaries paid to personnel officers and other members of personnel departments To collect this information, questionnaires were sent to companies throughout Britain and senior personnel officers were asked to complete these on behalf of their personnel staff. A report based on this survey was issued at the beginning of 1957. This report proved to be of great value both to individual members and also to companies filling vacancies or setting up personnel departments The Institute has now taken a further and more extensive survey to obtain an up-to-date review of members' salaries in Britain (Personnel Management Salaries Report of a Survey undertaken in February/March 1961 Pp 32. London Institute of Personnel Management, 1961. 21*s*) Of the 2,900 questionnaires sent out to practising personnel officers, approximately 1,250 questionnaires were returned, of which 1,222 were included in the final analysis The personnel officers completing the questionnaire can be regarded as representative of the Institute members as a whole The report consists of eighteen tables which give salaries paid under a number of different headings, including salaries according to positions held, age group, type of company, industry, area, length of time with the firm, and number of employees

The National Mineral Collection, Ottawa

A NATIONAL Mineral Collection, containing specimens from Canada and all over the world, has been established at Ottawa through the co-operation of two Federal Government departments The Collection will consist of two series a systematic reference series to be maintained by the Geological Survey of Canada, within the Department of Mines and Technical Surveys, with H R Steacy as curator, and a display series, in the National Museum, under the curatorship of Colonel E Taylor The Museum is within the Department of Northern Affairs and National Resources A single catalogue, to be prepared and maintained by the Geological Survey, will cover the whole Collection Both Departments already possess substantial collections of minerals, accumulated since the Geological Survey was formed in 1842 The number of specimens in the keeping of the Survey is estimated at 50,000 Among them are rare gold nuggets and precious stones, as well as large pieces of silver—one of them 3½ ft long—found by geologists, prospectors, and mining crews in many parts of Canada The curators of both series will endeavour to expand and to improve their series year by year The Collection now has specimens representing about 30 per cent of the world's known mineral types—a valuable aid to training and research in geological science and exploration

Recent Developments in Medical Treatment

A WELCOME sign of how clinicians are adapting themselves to the changing outlook in medicine is shown in the current issue of the *Practitioner* (187, No 1120, October 1961) This is a special issue dealing with advances in treatment, and three of the contributors do not concern themselves with 'treatment' in the narrow sense of the term The contributors in question deal with advances in pædiatrics, general practice, and public health, the inclusion of the latter subject indicating that preventive medicine is an integral part of the practice of medicine The reasons why the other two subjects have been dealt with in a particular way are given by the contributors themselves "The Holistic conception of child life within the family circle", according to Prof W S Craig, "is fundamental to pædiatric thought, and a knowledge of human relations, and of the art of consultation and physical examination, must continue to provide the foundations of pædiatric teaching". "Too often", according to Dr Richard Scott, "advance is halted by our failure to apply existing knowledge It would appear that, as in many other spheres, so also in medicine are we more skilful in advancing knowledge than in applying it" That 'treatment', in the narrower sense of the term, is not overlooked is well exemplified by the other fifteen articles in the symposium

The Perkin Centenary Trust: Awards

APPLICATIONS for the awards of the Perkin Centenary Fellowship and Scholarships are invited by the Trustees. *The Perkin Centenary Fellowship* is offered for one or two years for the purpose of higher study of any subject approved by the Trustees Candidates will be required to show either that they have had experience in an industrial firm or other institution concerned in the manufacture or the application of colouring matters, or that their intended field of study has a direct bearing on these subjects The value of the Fellowship is £750 per annum with an additional grant of up to £100 per annum towards certain designated expenses It is tenable, from October 1962, at any university, technical college or other institution approved by the Trustees *The Perkin Centenary Scholarship* two such awards are offered, each for two years, to enable candidates employed in an industrial firm or other institution concerned with the manufacture or the application of colouring matters to receive an education at a university or technical college Each award will have a value of £350 per annum This may be increased, at the discretion of the Trustees, to £400 per annum, if the candidate appointed is required to live away from his normal place of residence Applications and inquiries should be addressed to the Secretary, Perkin Centenary Trust, c/o Chemical Society, Burlington House, London, W 1 Applications must be made by May 1, 1962

The U S Building Research Institute

THE Building Research Institute, a constituent part of the Division of Engineering and Industrial Research of the U S National Academy of Sciences–National Research Council, will become an independent technical society for the building sciences next year As Dr Detlev W. Bronk, president of the Academy–Research Council, remarked· "The Buckley report, which recommended in 1951 the establishment of the Building Research Institute within the Academy–Research Council, recommended also that the Institute be encouraged to work toward independent status It is truly gratifying that, within the span of a decade, the Institute has established itself as a uniquely effective instrument for the stimulation and correlation of interdisciplinary research in the building industry, the extraordinarily diverse interests of which otherwise depend on the attention of nearly 500 separate associations in the field"

Acoustical Society of America

DR LEO L BERANEK, president of Bolt Beranek and Newman Inc , of Cambridge, Mass , has been given the Wallace Clement Sabine Award of the Acoustical Society of America for his contributions to architectural acoustics The Pioneers of Underwater Sound Award has been conferred on Dr A B Wood, of the Admiralty Research Laboratory, Teddington. The officers of the Society are as follows *President,* Dr Laurence Batchelder, Raytheon Co , Burlington, Mass., *Vice-president,* Prof Robert T Beyer, Brown University , *President-elect,* Dr Robert W Leonard, University of California at Los Angeles, *Treasurer,* Herbert A Erf, Cleveland, Ohio, *Secretary,* Wallace Waterfall, American Institute of Physics, New York; *Editor-in-Chief,* Dean R Bruce Lindsay, Brown University.

Biological Engineering Society

AT the annual general meeting of the Biological Engineering Society, Prof. R F. Woolmer was re-elected president for the coming year, and Dr A. Nightingale, St Thomas's Hospital, London, S E 1, as honorary secretary. The following members were elected as members of council P E. K Donaldson, D Gordon, A Nightingale, G Pampiglione, W J. Perkins, J T Scales, B Shackel, A. M. Uttley, H S Wolff, B M Wright.

University News : Birmingham

THE following appointments have been made Dr J S Brimacombe, to be lecturer in the Department of Chemistry, Dr F. Rieband, to be lecturer in the Department of Mechanical Engineering, E D R Shearman, to be senior lecturer in electromagnetism in the Department of Electrical Engineering, Dr E C Grant, to be Research Fellow in the Department of Medical Biochemistry and Pharmacology

Edinburgh

THE following appointments to lectureships have been announced I W Sutherland (bacteriology); J Shepherd (electrical engineering), W. Dudgeon (senior lecturer in engineering), J A Linnet (engineering), Dr S Soundranayagan (engineering), H Montgomery (pathology), M B Smith (pathology), Dr. P D Mitchell (senior lecturer in zoology)

London

DR J. CLUNIE, lecturer at the Imperial College of Science and Technology, has been appointed to a readership in mathematical analysis tenable at that College

New York

NEW YORK UNIVERSITY has combined its two physics departments into a single all-University department and has appointed Prof Bruno Zumino, professor of physics, as its head The re-organization is one of the final steps toward unifying the departments at the several centres of this University. The two units involved in the change are the University Heights Physics Department, formerly in the College of Engineering, and the Washington Square College of Arts and Science Physics Department Each of the physics units under Dr Zumino's direction will continue to have its own chairman. Prof. Sidney Borowitz has been appointed chairman of the University Heights Department to replace Dr Lyle Borst, who has assumed a professorship in the all-University Department of Chemistry Prof Morris H Shamos will continue as chairman of the Washington Square College of Arts and Science Physics Department.

Announcements

THE Executive Council of the Commonwealth Agricultural Bureaux has appointed Dr V Armstrong, representing New Zealand, as chairman in succession to Mr C K Reheem, representing Pakistan Mr W G Alexander, representing the United Kingdom, has succeeded Dr V Armstrong as vice-chairman

DR A W BALDWIN, formerly an associate research manager of the Dyestuffs Division, Imperial Chemical Industries, Ltd , has been co-opted as a governor of the J A. Radley Research Institute, 220–222 Elgar Road, Reading

DR ROBERT PHYFE MADDEN, chief of the Spectroscopy Section, Physics Research Laboratory, in the Engineer Research and Development Laboratories at Ft. Belvoir, Va , has been appointed to the Atomic Physics Division of the U S National Bureau of Standards His new group is to develop absolute radiation standards for the far ultra-violet spectral region

THE ninth annual Western Spectroscopy Conference will be held at Asilomar, Pacific Grove, California, during January 25–26, 1962 Further information can be obtained from Dr. Donald G Rea, chairman, Western Spectroscopy Association, Space Sciences Laboratory, Leuschner Observatory, University of California, Berkeley 4, California

ERRATUM In the communication by M R Droop entitled "Evidence for a Sexual Phase in the Life-Cycle of an Amœba" in *Nature* of October 21, p 281, par 2, lines 1 and 5, the names *Heteramœba* and *Heterochromonas* should be interchanged.

PHILOSOPHY OF SCIENCE

THE sixth annual conference of the British Society for the Philosophy of Science was held at St Hugh's College, Oxford, during September 22–24 The four formal meetings and discussions, once again organized by Dr Mary Hesse (Cambridge), were attended by eighty members and guests

The theme of the first meeting, with Dr B A Farrell (Oxford) in the chair, was explanation in psychology The first of the two papers was read by Dr M Treisman (Oxford), who challenged the widespread belief that, whereas the physical and biological sciences use only public data, the psychologist also uses private data of immediate experience Dr Treisman's method was to select topics from the history of psychology to show that the modern psychologist has refined the vague descriptive analyses of the past and now uses concepts as precisely definable and as objective as those of the physicist The first illustrative topic he discussed was the analysis of instinct He contrasted McDougall's classification analysis, vague and merely descriptive, with the present-day model of instinctive behaviour in animals based on the work of Lorenz and Tinbergen Here there was little to dispute though the argument edged close to the controversial issue of reductionism His second topic was the history of the measurement of sensation he described the experiments of Fechner and of Stevens and Davis which led to the apparently conflicting laws $S = K \log I$ and $S = K I^n$ respectively, where S is the 'measure of sensation' and I is the intensity of the stimulus Dr Treisman argued that these laws could be reconciled but that the second was preferable because it had more explanatory power

Dr. J O. Wisdom (London School of Economics) widened the scope of the kind of psychological explanation to be considered by discussing the hypotheses used by psychoanalysts to explain patients' associations Such an explanation, he argued, requires to be tested clinically by observing the patient's response to a presentation of an interpretation embodying the hypothesis But, following Seeborn Jones, he indicated that two problems then arise Does the presented interpretation cause a change ? Is the interpretation true ? He proffered some new criteria to distinguish between an interpretation that causes a change by suggestion and an interpretation that is true

A long and lively discussion ensued. The chairman began by challenging the assumption implicit in Dr Wisdom's paper that the reports of the psychoanalyst could be regarded as objective data, but, for an hour, discussion was focused on Dr Treisman's reconciliation of the two laws of sensation, a reconciliation which failed to satisfy the mathematicians present Eventually there was a return to psychoanalysis What are its basic statements ? To what extent could the reports of the analyst about his subject be regarded as objective data ? But again the discussion returned to the measurement of sensation How could 'half a feeling' be measured ?, the physicists demanded Various solutions to the many problems raised echoed along the corridors of St Hugh's until well after midnight

At the next session the president, Prof R B Braithwaite (Cambridge), took the chair for a discussion on learning machines Dr F H George (Bristol), treading delicately over this philosophically thorny field, outlined some of his recent work He gave a lively description of his method of programming a *Deuce* computer so that one-half of the machine taught the other half to play an optimal game of noughts and crosses—a by no means trivial game, as the chairman had later occasion to emphasize. Dr George went on to explain more generally how a computer can 'learn' to generalize from its own experience and to symbolize or 'name' the processes it goes through He suggested that such performances give the computer qualities analogous to the insight and flexibility of human thought-processes

Prof D M Mackay (North Staffordshire) gave a thoughtful elaboration of Eddington's account of 'the two tables' extended to persons (and their brains) and to machines He first considered the transition from the micro-description of a mechanism to its behavioural description in such terms as 'controlling' and 'goal-seeking' He argued that such behavioural terms presuppose an under-specification of the physical situation which becomes meaningless when applied to mechanisms specified in atomic detail He then extended his analysis to 'game-playing' mechanisms and explained how the crucial difference between playing against and manipulating a machine lies in the nature of one's commitment towards it Finally, he extended his analysis to human beings, regarded as persons and as cell-mechanisms, and discussed the degree to which it is possible to switch from one view to the other when one is confronted by another human being

In the discussion Dr George was asked to elucidate some technical points, but members' questions mainly sought clarification of Prof Mackay's concept of under-specification, its relation to entropy and its implications for personal commitment in dialogue

The third meeting was devoted to a discussion of genetic coding and information theory, with Mr F T C Harris (Middlesex Hospital Medical School) as chairman. Dr I Leslie (Belfast) gave the first of two papers Using a helpful series of slides, he reviewed with modest impartiality some recent developments in the biochemical analysis of the processes by which information is transferred from the genes to the cellular sites of protein synthesis He explained the background to the present conflict of ideas about the way in which ribonucleic acid (RNA) acts as an intermediary in this transference In the 'classical' view much of the RNA is in the form of stable templates which are coded by DNA for the synthesis of specific proteins but recent experiments on bacteria and bacterial viruses suggest that some of the RNA acts as a 'messenger' which itself carries genetic information from the genes to the protein-synthesizing mechanisms

The second main speaker, Dr S Brenner (Cambridge), remarking that "philosophers are not really concerned with the facts", bounded gaily from Dr Leslie's well-laid factual foundations into genetic space He delighted the audience with bold speculative leaps and a frank analysis of his own approach to the problem He based his study of genetic coding, he explained, on two main principles: (1) that "anything useless must be wrong", and (2) that "there is no security problem in Nature", that is, Nature is no enemy striving to conceal the truth from us. He then attacked the view that the stable RNA of the ribosomes acts as a template and argued that the ribosomes are structures which synthesize, at a given time, the protein dictated by the attendant messenger. Thus he rejected two- and three-process models of transfer of information in favour of a one-process model which he claimed was universal.

The discussion was at first confined to thrust and counterthrust between the two experts, deftly provoked by the chairman. But gradually the audience gained sufficient confidence to intervene. Questions about the evolution and the controlling mechanisms of this complex system (for example: How do you make a cat ?) led to lively discussions. It slowly became apparent that though genetic coding was concerned with transfer of information, information theory itself had little to offer in solving the problems of genetic coding apart from providing some descriptive terms. As Dr Brenner put it in his final remark, "It's now just a matter of linguistics", that is, of reading the code.

The fourth and final discussion was devoted to philosophical aspects of cosmology. Prof J. L. Mackie (Sydney) took the chair, and Mr R. Harré (Oxford) and Dr. W. Davidson (Battersea College of Technology) were the two main speakers. Mr Harré argued that the universe, defined as 'everything there is', was logically not a proper subject for scientific study. He carefully distinguished between the cosmo-sciences and the astro-sciences by analysing the logical form of typical propositions of these subjects; though cosmography, he thought, could be regarded as scientific, the other cosmo-sciences, cosmogeny and cosmophysics, were merely speculative. His main attack centred on the concept of infinity as used in or implied by the cosmo-sciences: he distinguished between the concept of an actual or referential infinity, which he rejected as logically improper, and the concept of a descriptive infinity which (analogously with the intuitionist concept of infinity in mathematics) has a finite starting point and a rule of progression which may continue without limit and thus be a growing but potentially infinite sequence.

Dr. Davidson argued that development of the cosmo-sciences was scientifically both valid and feasible, and that such questions as whether the universe is spatially infinite or not, or whether it had an origin in time or not, are not necessarily transcendental issues. He claimed that the unity of science as a whole may depend on the development of a satisfactory cosmology in which every science could find its place.

With the two protagonists thus apparently diametrically opposed, the chairman formulated their main differences and members of the Conference set about their task of resolving them. In the discussion, Mr Harré's dependence on Kantian antinomies, Russell's theory of types, and *a priori* arguments took some hard knocks. It seemed eventually that perhaps only the philosopher's concept of the universe was referentially infinite, while the cosmologist's universe, if not finite, was at worst only descriptively infinite and therefore not, logically, a wholly improper subject of study.

The conference ended with a business meeting at which, *inter alia*, members were able to express their thanks to St. Hugh's College as hosts and to Dr Mary Hesse as organizer for the parts they played in a pleasant and stimulating week-end.

B. C. BROOKES

IONIC MELTS

LIQUIDS still constitute one of the least well understood states of matter. Near the critical temperature various quasi-gaseous formulations of their behaviour are often quite successful, but near the melting point quasi-crystalline models offer more promise. Ionic melts have been much less studied than many other liquids. Their critical temperatures are usually not known, but are certain to be high. For this reason, current structural models for ionic melts show a bias towards quasi-crystalline concepts, which is strengthened by the strong statistical probability that each cation will have anions as its nearest neighbours, and vice versa, in order to lessen electrostatic repulsion energy.

However, really precise theories of the structure of ionic melts present difficulties which have not yet been surmounted. In addition to the theoretical difficulties, until recent years the amount and diversity of experimental work on ionic melts has been restricted by technical complications. Temperatures of study need to range from 100° to well above 1,000° C., and many of the melts attack practically every kind of containing wall. Despite these obstacles, interest in the science and technology of ionic melts has been growing rapidly. Sessions dealing with these systems have been included in a number of recent international scientific meetings, and two Gordon conferences in the United States have been wholly devoted to discussing their properties. At the discussion meeting of the Faraday Society, held in the University of Liverpool during September 5–7, seventy-five scientists from Britain and fifty from overseas had the opportunity of comparing progress in three main fields: structure, thermodynamic properties, and transport properties of ionic melts. The president, Sir Cyril Hinshelwood, was in the chair. Prof H. Bloom, of the University of Tasmania, gave the eleventh Spiers Memorial Lecture on "Structural Models for Molten Salts and their Mixtures".

A broad conclusion from the discussion was that interesting and important experimental work is being carried out in quite a few centres. Comprehensive theoretical treatments of the properties of ionic melts have by no means caught up with the range or the physical interest of the data now being obtained. Applied research on ionic melts in electrometallurgy or as heat-transfer fluids appears to be reasonably active in various countries. The number of substances capable of existence as stable liquids in the range 300–1,000° C. is comparatively small, which points to the profitability of exploring further fields of application of ionic melts. At present, basic research on ionic melts seems scanty in British universities, having regard to the importance of extending physicochemical research to higher temperatures, and to the properties of condensed states of matter generally.

The first group of six papers presented at the Liverpool meeting of the Faraday Society were concerned with structure and spectra. In dealing with problems of structure, methods of describing and measuring the nearest neighbour and next-nearest neighbour environment of any ions continue to be of prime importance. Although they are indispensable, X-ray techniques applied to ionic melts suffer from the weakness that as with other liquids they only yield information in the form of radial distribution functions, which give average environments. In a significant number of ionic melts, there is evidence for a closer approach between anion and cation, and an increase of separation between ions of like sign, compared with the crystals. This shrinkage of contact distance between ions of unlike sign has been explained in terms of the increased positional disorder in the melt, compared with the crystal. Disorder results in less complete compensation of electrostatic forces from the nearest neighbour shell of unlike ions, exerted on the ion at the centre of the shell. Greater local polarizations can be expected in the melt, even when the total volume it occupies is larger than when the same quantity of matter is in the crystalline state. Data were presented for radial distribution functions of molten carbonates and sulphates.

There was considerable discussion about the local arrangements of ions in close-packed melts. Spectroscopic techniques promise to give rather more specific information about local structure than is obtainable from X-ray determinations of radial distribution functions. Experimental studies presented for discussion included ultra-violet absorption spectra of transition metal ions in dilute solution melts. These yield information about ligand fields around the transition ion. A somewhat different type of ultra-violet absorption spectrum arises from so-called charge transfer effects, which involve excitation of an electron in the anion to an orbital the radius of which depends on that of the shell of cations immediately surrounding the anion. Such spectra can therefore yield valuable information about the configurational changes in this shell of nearest neighbours. One paper dealt with the modifications of charge transfer spectra that accompany various changes such as thermal expansion, the transition from one crystal form to another, and the transition from crystal to melt. Thermal expansions of crystalline nitrates observed by conventional means are found to match quite closely the expansions of the charge transfer orbitals as determined by the ultra-violet absorption spectra. This makes it all the more striking that volume changes on melting, as determined by conventional methods, are in the opposite direction to the changes in the charge transfer orbitals. Compared with the crystals, optical evidence for the melts thus points to a greater proportion of more tightly packed local assemblies of ions. Since the thermodynamic evidence shows an increase in volume, presumably this expansion results from increasing the proportion of vacancies and holes on melting alkali nitrates. Rubidium nitrate is one of the very few crystals which shrink on melting. Even here, the shrinkage of the charge transfer orbitals appears to be greater than the average contraction observed thermodynamically. For nitrates and other salts of polyatomic anions that have low melting points it is claimed that spectral evidence supports the general theory that the melting mechanism of these crystals includes the formation of 'association complexes', as well as the more usual increase of positional disorder and randomization of orientation of non-spherical ions. A second paper on charge transfer spectra described changes in mixed molten nitrates in terms of the effective electrostatic fields due to neighbours and next-nearest neighbours. Interesting information about the structure of liquids seems likely to emerge from extensions of such studies on mixtures of molten salts.

There was considerable but not very conclusive discussion about the usefulness or otherwise of attempting experimental and even conceptual distinction between 'association complexes' and 'complex ions'. It seems to be generally agreed that complex ions can be readily distinguished when they are formed in dilute solution in ionizing solvents, many techniques for their identification have been developed since Arrhenius. In condensed ionic assemblies, whether crystalline or molten, the distorting influence of nearest neighbours can make identification of a complex much less discriminating. 'Association complexes' can be the result of various ways of packing ions so as to minimize their potential energy. In discussing melting mechanisms, it is important to recognize that some of these packings are 'non-crystallizable', for these, addition of more and more ions according to the same rules of packing will not fill space economically. Only crystal nuclei can be extended by packing additional ions indefinitely in three directions in space, but so long as they are quite small, non-crystallizable association complexes may compete thermodynamically with potential crystal nuclei in the melt, which can be regarded as containing a mixture of the various kinds.

For discussing melting mechanisms, it may not be necessary to decide whether the reduction of potential energy on passing from random ionic packing to an association complex results primarily from electrostatic effects, or whether recognizable 'complex ions' are formed in which delocalization of valency electrons may extend over all the atoms in the complex.

But for the interpretation of other properties of ionic melts, the identification of strongly bonded complex ions may be more urgent. For example, cryoscopic measurements continue to yield suggestive structural information. One group of studies presented for discussion referred to the formation of complex ions such as $CdCl_3$ or $PbCl_3^-$ analogous to those encountered in aqueous ionic solutions.

A novel field is opened up by cryoscopic and other studies of the behaviour of solutions of metals in ionic melts. In some of these solutions the electron appears to leave the metal atom and may have a role analogous to that in solutions of alkali metals in liquid ammonia. Theoretical and experimental aspects of the electronic properties of such solutions received considerable discussion. Transport of electrons under the influence of electric fields applied to such systems has interesting contrasts and analogies with the movement of charge carriers in semiconductors. Conductances can be quite high even when the concentration of the metal atom is fairly dilute. Developments of these investigations promise to throw much additional light on conductance mechanisms generally that do not involve ion migration in condensed phases.

Papers presented at the meeting point to significant advances in the precision of measurement of basic thermodynamic parameters of ionic melts, such as activity coefficients Evaluations were reported of excess functions for the enthalpy and changes in volume on mixing ionic melts of the same or of different valency structure As a result, some of the current quantitative theories that have been developed for non-ionic liquid mixtures can begin to be adapted to ionic melts Considerable advances may be expected in the next few years in this branch of the theory of liquids

One-third of the papers presented dealt with transport properties of ionic melts, which have been studied for a number of years and which continue to receive much attention Use of radioisotopes has greatly enriched the possibilities of making measurements on diffusion, the correlation of which with other transport phenomena helps to unravel complicated structural problems In addition to their technological importance, transport properties can yield tests of theoretical models for ionic melts that can be much more sensitive than equilibrium properties to structural details assumed in the model Discussion of measurements of thermo-electric power of ionic melts suggested further interesting possibilities that seem likely to attract additional attention in the years ahead A R UBBELOHDE

WOOD EXTRACTIVES

A SYMPOSIUM on wood extractives was arranged by the Plant Phenolics Group and held at the Royal Holloway College, Englefield Green, Surrey, during September 20–22 The meeting proved valuable in bringing together workers in different fields, including several from overseas, having a common interest in the minor or extraneous components of woods After an introductory session the subject of wood extractives was dealt with under three headings, namely biosynthesis and taxonomy, the chemistry of extractives, and their influence on utilization of wood and wood products

Dr F E King (British Petroleum Co, Ltd) opened the symposium with an introductory address entitled "Perspectives in the Chemistry of Wood Extractives' Dr King surveyed the historical development of investigations on extractives, commencing with those of technical interest such as the tannins, dyestuffs and resins, and proceeding to the work of Erdtman on the heartwood components of coniferous trees and his own work on the corresponding components of hardwoods These investigations led to the conception of heartwood components as 'taxonomic tracers' which can be used to supplement the observations on morphological features employed by botanists in the taxonomic classification of trees Dr King emphasized the wide variety of C_6–C_3–C_6 compounds that are found in woods and discussed a few unusual structures that have been encountered

In the second paper, given by Prof F W Jane (Royal Holloway College), an account was given of the structure of the tree and the distribution of the various tissues in it This was helpful to the audience, consisting predominantly of chemists The extraneous substances are classified by botanists as gums, resins, tannins, oils, mucilages, colouring matters, mineral deposits, etc, and the location of these in the structure was described and illustrated There is clearly room for closer co-ordination between the observations of botanists, based largely on the microscopic staining reactions of these components, and their investigation by chemists

Prof E J Bourne (Royal Holloway College) described some new methods for the characterization and separation of extractives that have been studied in his laboratory These include the use of molybdates and tungstates which form complexes with polyhydroxy compounds and can assist in their separation by electrophoresis, the addition of phenylboronic acid to the solvents used in paper chromatographic separations of these compounds, the use of boron trichloride under very mild conditions to identify families of extractives by removing substituent groups, and the fractionation of mixtures by means of a new liquid/liquid countercurrent extraction technique, which was demonstrated

The session on biosynthesis and taxonomy opened with a paper by Prof W Sandermann (Bundesforschungsanstalt fur Forst- und Holzwirtschaft, Reinbek, West Germany) on the biogenesis of terpenes in plants Prof Sandermann discussed the part played by mevalonic acid and its conversion into geranyl and farnesyl pyrophosphates, from which the more complex terpenes may be derived He then described his work on the incorporation of labelled precursors in plants and showed how a distinction between alternative mechanisms can be made by these methods, for example, the biosynthesis of α-pinene and thujone was shown to take place by an electrophilic substitution rather than by an addition mechanism A series of terpenoid compounds has been found in teak and correlated structurally with the anthraquinones present in this wood

The systematic distribution of phenolic substances in plants was discussed by Dr E C Bate-Smith and Dr T Swain (Low Temperature Research Station, Cambridge) in a paper presented by Dr Swain The contribution that a study of the chemical components of plants can make to taxonomic classification was emphasized One of the results of an extensive survey of the occurrence of the common phenolics is the recognition that plants in some families or higher groupings are devoid of the capability of synthesizing certain types of compound In this connexion the occurrence of compounds containing vicinal trihydroxy groups and of ellagic acid in members of the Rosaceae was discussed

In continuation of this theme Prof C W L Bevan (University College, Ibadan, Nigeria) presented a paper entitled "Wood Extractives as Tracer Substances in Taxonomy', and referred particularly to the results of a survey carried out in his Department of components of woods of the family Meliaceae He also outlined the procedures followed in determining the structures of gedunin, isolated from *Entandrophragma angolense* and of khivorin from *Khaya ivorensis* and *K grandifoliola*

In the session on the chemistry of wood extractives four papers were presented, dealing respectively with the lignans, tropolones, stilbenes, and flavonoids, these being the principal types of phenolic compounds that are found in wood In discussing the lignans Prof R D Haworth (University of Sheffield) pointed out that the basic structure common to all lignans comprises two phenylpropane units linked in the β-positions The structure and stereochemistry of some of the naturally occurring lignans, of which about forty are known, was considered Where ring closure has occurred, with formation of phenyltetralin or furano-structures, the creation of a new asymmetric carbon atom renders the stereochemistry complex There is evidence that the lignan structure can be formed by oxidation of αβ-unsaturated phenylpropane compounds, such as ferulic acid.

A survey of the discovery and determination of structure of the tropolones found in various woods was given by Prof. J Gripenberg (Institute of Technology, Helsinki, Finland) The distribution of the tropolones, which appear to be confined to the family Cupressaceae, was discussed and their general properties and synthesis described. It is interesting to note that all the nine known tropolones occurring in wood contain an isopropyl (or isopropenyl) group and appear to be closely related to the terpenes A scheme by which they may be derived from carone has been proposed by Erdtman.

Dr D E Hathway (British Leather Manufacturers' Research Association) discussed the occurrence of stilbenes in wood and referred to the recorded incidence of hydroxystilbenes in conifers and dicotyledonous trees In a study of the extractives of the heartwood of *Eucalyptus wandoo*, 3 5·4′-trihydroxystilbene and its 3-glucoside were found to be present, and these compounds have been used as tracer substances in an investigation of the heartwoods of 60 species belonging to the *Longiores* sub-section of the genus *Eucalyptus*. This method confirms the existence of certain anomalies in the classification that have been suspected on other grounds

The fourth paper in this group, dealing with the flavonoids, was prepared by Dr. R A. Laidlaw and Dr J W W Morgan (Forest Products Research Laboratory) After a short account of the occurrence, function and nature of the flavonoids of wood, Dr Laidlaw went on to consider three classes of these compounds, namely the leucoanthocyanidins, dihydroflavonols and benzylcoumaranones, in greater detail. Methods for determination of the structure and stereochemistry of the leucoanthocyanidins and their characterization as flavan-3 4-diols were discussed. Among the dihydroflavonols, dihydromorin, phellamuretin and keyakinol were selected for special mention The naturally occurring aurones and hydroxybenzylcoumaranones were described and the behaviour of maesopsin (tetrahydroxybenzylcoumaran-3-one) on heating with alkali was discussed in detail.

The final section of the symposium consisted of two papers in which different aspects of the utilization of wood were considered. Dr R H Farmer (Forest Products Research Laboratory) discussed the influence of extractives present in different timbers on some of their technically important properties and applications A brief account was given of the manner in which the colours of woods (and the changes in colour occurring under certain conditions) and their natural durability are related to the chemical nature of the extractives present in them. Examples were then given of interaction between wood components and other materials with which the wood comes into contact These include the inhibition of the hardening of unsaturated polyester resins by certain timbers, shown to be due generally to quinones or hydroxystilbenes, and the retardation of setting of cement by water-soluble sugars and tannins

In the final paper Prof B Lindberg (Swedish Forest Products Research Laboratory) described the influence of extractives on the pulping of timber Extractives can influence the sulphite or the alkaline pulping processes in various ways Thus they may render the penetration of the cooking liquor into the wood more difficult, react with the cooking liquors and modify them, or condense with the lignin, preventing its dissolution Resinous and fatty components may give rise to 'pitch troubles', and can cause difficulty in bleaching because chlorination renders them more lipophilic R. H. Farmer

THE INTERNATIONAL SCIENTIFIC FILM ASSOCIATION

FIFTEENTH CONGRESS

The fifteenth annual congress of the International Scientific Film Association was held at Rabat, Morocco, during September 14–20, 1961 This was the first time that the Association had met outside Europe. The congress was under the patronage of H R H Prince Moulay Abdullah

Of the Association's twenty-five member countries, sixteen sent delegates and there were also observers from Guinea, India, Indonesia, the Lebanon and Mali. The largest delegation of twenty-two people was from Great Britain, followed by the U S S R with about twenty

All delegates, observers and friends enjoyed the gracious Moroccan hospitality From Rabat, where all were well housed in the new Cité Universitaire, excursions were made to Casablanca, Fes, Meknes and Marrakech As the sun shone without hesitation throughout each day on every day, expeditions were also organized to the delightful beach at Temarah

In his address of welcome, M Moulay Ahmed Alaoui, Minister of Information, Fine Arts and Tourism, expressed his country's pleasure at the honour being paid to Morocco as the scene of the congress This indicated also the importance of the African continent in the building up of the modern world For countries like Morocco, the cinema was not a diversion, but an important instrument in education and instruction

This congress has always two aspects one organizational, the other concerned with the problems of scientific film makers The former provides the machinery whereby the film makers can get together and see and discuss films in three main sections research, education and popular science For some time there has been a feeling that the organization has needed tightening, and this congress took certain steps to do so The new president is Mr Edgar Anstey (Great Britain), who replaces Mr Alexandre

Zgouridi (U S S R). The new honorary secretary is M Mohammed Afifi (Morocco), who replaces Mr John Maddison (Great Britain) It is Mr Maddison's guiding hand in the main which has been responsible for the steady development in the influence and prestige of the Association He has now been elected an honorary life member

The thirty films shown to the Research Section were described by its president, Dr. R Robineaux (France), as on a very high level Five films from France, two from Western Germany, and one each from Italy, the Netherlands and Czechoslovakia were specially selected by the Section for commendation At the discussions the special theme was new techniques The French described some new tools to aid research These included

(1) The light helper (this is a free translation of *l'asservisseur de lumière*), an instrument which allows the time of placing of the camera on the desired part of the curve of spectral sensitivity of the film to be fixed exactly and automatically, without acting on the diaphragm and without having to worry about rectifying the time of placing during the forward movement of panning of the camera It can be used in particular for taking shots automatically and slowly during daylight ; for example, during the complete phase of a solar eclipse when there are enormous differences in light. The instrument is a kind of 'cybernetic' tool

(2) The *brillancemètre*, which is incorporated in the camera to allow of instantaneous control of the mean brilliance of the image

(3) Motor regulated by transistor, a motor with continuous current fed by 8-, 12- or 24-V batteries, with transistorized regulation between 8 and 40 images a second, to which a small frequency emitter can be added to record sound on a separate magnetic tape at 24 or 25 images a second, even with differences in tension of several volts in the batteries

There was also a description of an apparatus to take under-water pictures with automatic illumination with synchronized flash It was developed primarily with biologists in mind, but has been of interest also to industrialists for the study of corrosion of submerged mechanical parts, and for the study of currents and their effects on public works and harbour installations.

Dr G Wolf, director of the Institut fur den Wissenshaftlichen Film, Gottingen, described how the film was being used for research in agriculture Evenly distributed rye was fed over an endless belt into the bar drum of a threshing machine In it the stresses to which the grain was subjected were observed and gauged With a circumference speed of the drum of 30 m /sec , the grain moves about two-thirds more slowly The flow of the threshed grain follows with irregular density due to congestion in the entrance An analysis was made of exactly what happens in the different parts of the threshing cage and productivity was increased Similar film analysis was done on the cutting capacity and cutting quality of the lawn-mower and hedge-cutting machine, which have developed empirically

Mr L Hallett and Mr John Maddison, both of Great Britain, read a paper on the "Use of Time Lapse in Research"

Thirty-eight films were exhibited for the Education Section Unfortunately, as the president, Prof J Jacoby (Poland), stated, there were no films from Great Britain or the U S S R these had been sent but had been mislaid Prof Jacoby was highly critical of the films seen He thought the quality was lower than that he had seen at any congress However, special mention was made of the films from Eastern Germany, which were commended for the high overall quality of their entry

Prof Jacoby said that screening conditions had made it impossible to appreciate the full technical quality of 16-mm films He wanted national branches of the International Scientific Film Association to take special care about the selection of films in future

Seventy-two films were shown to the Popular Science Section These were also of uneven quality and, as the president, Mr V Tosi (Italy), said, there was a great need for a clearer statement of the role and nature of the popular science film

Running at the same time as the congress, was a festival of popular science films which were shown nightly and were open to the public These films were included in the viewing by a special jury set up to recommend the outstanding popular science films of the congress. The following films were selected Great Britain, "Electron Microscopy", made by A E I , Eastern Germany, "Robert Koch", Bulgaria, "Life in a Drop of Water", Czechoslovakia, "Secrets of Heredity", Hungary, "Silver Threads", France, "Thaumetopoea", Rumania, "Coke", U S S R , "Colour TV", Poland, "The Gulf of Polar Bears" The British film, "Wild Highlands", made by the British Transport Commission, was mentioned for the high quality of its production and two Japanese films, "Lubricating Oil" and "Ancylostoma" were commended for their high technical quality. The Moroccan Scientific Film Association, as host country, awarded a diploma to the Japanese for their entries as best fulfilling the aims of the Association

There was a special session on television, at which the main speaker was Mr Aubrey Singer (Great Britain). of the B B C During the past year, a commission for the study of problems of the use of television has been working Its secretary, Mr. Jean Le Harivel (Great Britain), presented a detailed report based on information received from eight countries

Most countries have some kind of science programme which goes out generally in the evening and is intended for large audiences of adults Several countries produce science programmes for schools A few countries have used television for the education of adults This is true of Eastern Germany, with its television academy (mathematics and chemistry), of Czechoslovakia, of France, which has started technical education programmes and which is planning a series for workers on the social significance of technological developments, and of the United Kingdom, which is planning for 1962–63 a series of topical education programmes to supplement existing technical courses In the United States, "Continental Classroom" is a television programme for the teaching of teachers It goes out at 6 30 a m to a weekly audience of 1,700,000 through 150 stations

Mr Jan Varossieau (Netherlands) of the Stichting Film en Wetenschap Universitaire Film Institute, described the use of closed-circuit television for the teaching of science in the universities A van had been fitted out to tour the country It carried a Philips compact 'Vidicon' transistor camera This could be linked to monitors in the lecture hall

The congress agreed that closer co-operation between film and television producers would be of mutual benefit, and that there was a great need for centralized information services

Information was given of the detailed plan prepared by the Association for Unesco to facilitate the distribution of films to universities The purpose is to prepare a select list of films which could be used in first- or second-year university courses and of which it is possible to supply copies This is an experimental project and the number of subjects to be covered and the number of films to be selected is limited In co-operation with the International Council of Scientific Unions, a list of subjects has been prepared, reported Mr B Chibnall (Great Britain) the director of the project The list includes subjects in botany, zoology, geology, chemistry and physics

The International Film Library has been set up in Brussels, during the past year It is having some initial troubles, but the Belgian Government has given a generous grant and premises Among the directors are Mr Edgar Anstey and Mr John Maddison (both of Great Britain)

Among other decisions taken at the congress were to investigate the possibility of compiling and having published an international multilingual standard reference journal and vocabulary of scientific cinematography, and to standardize film catalogues An offer by the Moroccan Government to investigate the possibility of setting up a distribution centre in Africa for scientific films was accepted Two newly elected member countries of the Association are the United States and North Korea This brings the total of member countries to twenty-seven, with three corresponding member countries

The new officers of the Association are as follows *President*, Edgar Anstey (Great Britain), *Vice-presidents*, J Jacoby (Poland), S Okada (Japan), R Whaley (U S A), A Zgouridi (U S S R), *Hon Secretary*, Mohammed Afifi (Morocco), *Hon Treasurer*, Vladimir Vaclavek (Czechoslovakia)

The editor of *Scientific Film*, the official organ of the Association, is Mr Maurice Goldsmith, c/o The Scientific Film Association, 55a Welbeck Street, London, W 1. The 1962 congress is to be held in Warsaw, and the 1963 congress in Rome M GOLDSMITH

EDUCATION IN EMERGENT COUNTRIES

FORMERLY an outstanding educational administrator in New Zealand and now his country's Ambassador to France and permanent delegate to Unesco, Dr C E Beeby presented an interesting paper on September 5 to Section L (Education) of the British Association for the Advancement of Science meeting at Norwich The paper was based on Dr Beeby's experience with the growth of educational services in newly developing countries, and especially Western Samoa, but also drew from his wide acquaintance with the evolution of educational systems in Western countries

Dr Beeby showed that, while it has taken England a hundred years to work out a system of universal primary education fairly well adapted to the needs of the community and to the varied capacities of the children in schools, a number of emergent countries is now trying to do the same thing in a decade At first sight it might appear that, with Western aid and benefiting from Western experience, they could leap the century and establish straight away something approaching a good modern type of classroom without having to plod through the stage of dreary formalism that marked the first fifty years of the Western system of compulsory schooling

The position is not as simple as this, and the 'expert' advising an emergent country on its primary school system finds himself in the position of a butterfly teaching the chrysalis how to fly There is an intermediate stage which must be gone through before some of his advice is of much significance Dr Beeby became aware of this sixteen years ago when he had some responsibility for the control of two education systems that were, at that time, at least half a century apart He found himself, without any sense of inconsistency, encouraging in Western Samoa the introduction of the formal educational practices which he had for a long time been combating in New Zealand This led to the conception of stages of development in the life-history of an education system, stages through which all systems, at least of a certain type, must pass, and which, though they may be shortened, cannot be skipped

The inability of a primitive type of school system to profit immediately from all that has been learned about modern teaching methods is in no way due to any innate inferiority of either children or teachers in emergent countries It depends primarily on two professional factors—the level of general education of the teachers in the system, and the amount and kind of professional training they have received On this basis the development of an education system could be roughly divided into three stages (1) 'dame school' stage, where teachers are ill-educated and untrained, (2) stage of formalism, where they are ill-educated but trained , (3) stage of meaning, where they are relatively well educated and also trained At the dame school stage the syllabus consists of little but mechanical drill on the three R's and the memorizing of relatively meaningless symbols The unsophisticated and untrained teacher turns naturally to formal methods of teaching, and the real weakness of the teaching at the dame school stage is that it is confusedly and inefficiently formal It has all the defects of formalism and none of its virtues , it is formalistic in spirit without having form

At the other end of the scale the main characteristics of modern education, in spite of its failings, are the attempt to give the child a deeper and wider understanding of the meaning of the symbols with which he works Practice in a good modern school is free, informal, and apparently 'natural' , but it is based on a complex and sophisticated structure of theory, and, to succeed, it demands teachers who are both well-educated and well-trained This is a long step from the ill-educated and untrained teacher at the dame school stage and in between must inevitably come the stage of formalism where teachers are still ill-educated but are trained For sheer formlessness the only remedy is more form, however much one may dislike formalism as such in education

The freedom and informality of the modern classroom depend on the teacher being sure of himself and of his subject-matter, and a teacher who is teaching at the very limits of his knowledge can have no sense of security if he or his class wander beyond the bounds of a tight official syllabus or the paste-board covers of the one official text-book The only questions he can allow are those he asks himself, for they are the only ones of which he can be sure of knowing the answers So the classroom must become formal At the stage of formalism, symbols have more meaning for children than at a dame school stage, but it tends to be a narrow and restricted meaning Classroom facts and skills are thin disparate things that mesh poorly with one another and scarcely at all with the warm rich world of the child's personal life

It is tempting to try to find a short cut from the dame school stage or the lower levels of the stage of formalism to the best of modern teaching methods, but there seems little hope of this if the difficulty to be overcome is really the meagre education of the teachers who are themselves the products of the schools one is setting out to reform With help and advice, the stage of formalism can certainly be reduced in length, but the reform of a school system is a skilled and delicate business, where too much haste can create confusion, and where our own unanalysed experience may not always be the best of guides The difficulty is increased by the fact that not all the teachers in a system at any moment have the same capacity to take up new and complex methods

A new element of urgency has developed with the explosive demand for education in newly independent States that has been one of the striking characteristics of the past decade The demand for education, indeed, has become a new political force in the world, a force that no democratic Government can long resist, and countries are sometimes driven to launch ambitious schemes of universal education before they have teachers with enough education to make them effective Unless there is to be a great waste of effort and grievous disappointment with the results of popular education in emergent countries, there is urgent need for a scholarly study, from a new and practical angle, of the whole natural history of the educational system and of the factors that help or retard its progress from stage to stage

EXPECTATION OF LIFE IN THE UNITED STATES

A RECENT report issued by the Metropolitan Life Insurance Co , New York, directs attention to the fact that the average length of life (expectation of life at birth) among industrial policy-holders reached a new record of 70 5 years in 1960* This is slightly above the figure for 1959, and only half a year greater than that for 1955 But although recent increases have been limited, long-term gains have been very impressive Five years have been added to the average length of life of these policy-holders since 1946, ten years since 1937, and twenty-four years since 1909 In 1879–94, the earliest period for which data are available, the average lifetime was only 34 years—less than half that for 1960

The largest gains in expectation of life have occurred at the younger ages Thus, at the age of 5, the figure for 1960 was 5 9 years greater than that two decades ago At the age of 40, the increase since 1940 has been 4 3 years, while at 65 the average future lifetime of those insured has been extended 2 3 years to its present level of 14 2 years

The longevity of American wage-earners and their families has increased more rapidly than that of the general population of the United States In 1909, the expectation of life at birth of the industrial policy-holders was about six years less than that of the population as a whole By mid-century the two groups were on a par, at present industrial policy-holders have a slight advantage

The long-term achievements in the conservation of life are accentuated by the very low death-rates now experienced in early life Mortality of the coloured policy-holders, particularly beyond childhood, is considerably higher than that for whites Among females, the rates for the coloured are at least double those for the whites from age 23 to the end of the child-bearing period Even though the difference is not as large for males, the ratio of mortality among them for the age-range 24–39 is more than 3 2.

Similarly, the average length of life is appreciably greater for white than for coloured policy-holders, and in each race is greater for females than for males In 1960, the expectation of life at age 5 years was 70 7 for white females, compared with 66 2 years for coloured females, the corresponding figures for males were 63 8 and 61 9 years

THE AMERICAN ACADEMY OF ARTS AND SCIENCES

THE *Records of the American Academy of Arts and Sciences 1960–1961** includes, as usual, the list of officers and committees, lists of members (including those elected May 10, 1961) with alphabetical index, the statutes and charter of incorporation, and reports submitted at the annual meeting Special interest is given by the valedictory address of the retiring president, Kirtley F Mather, which, under the title "Assay and Perspective" reviews the activities of the Academy during the four years of his presidency before appraising the present position of the Academy and its responsibilities and opportunities during the next decade While it was doubtful whether the fullest possible use had been made of the Academy's new house, Mr Mather thought that the success in developing its publication *Daedalus* as a journal of ideas and opinion had been outstanding and the Academy had been most successful in its development of conferences on topics of wide importance and interest

As regards research, 119 grants totalling 91,903 dollars had been made in the past four and a half years, compared with 452 applications aggregating more than 500,000 dollars, and the Academy was seeking to increase the number and scope of its awards for recognizing excellence, as yet it had no such award in the social sciences corresponding with its Rumford Medals in the physical sciences, the Amory Prizes in the medical sciences and the Emerson–Thereau Medal in the broad field of literature. The Academy had made no public pronouncement during the period, but Mr Mather was not satisfied that there had been a suitable theme, and he inclined to think that the Academy was doing what it should more effectively by providing the information to illumine the problems on which policy makers must make their decisions.

---

* American Academy of Arts and Sciences, Boston Records of the Academy (including new members elected 10 May, 1961), 1960–61 Pp 157 (Boston, Mass , American Academy of Arts and Sciences, 1961)

As regards the future, Mr Mather said that the Carnegie Corporation had made a grant of 50,000 dollars for each of the next two years for the continuation of the Academy's conference and study programme It would be necessary in the next four years to assess the value of the Academy's house and the function of the Academy in the State, but he thought that the Academy's outstanding opportunity and responsibility in the next decade lay in serving as a liaison between the community of practical affairs and the practitioners and scholars in the arts and sciences

BRITISH COLUMBIA RESEARCH COUNCIL

AMONG the varied research items described in the seventeenth annual report of the British Columbia Research Council is one into marine borer control (Pp 16 Vancouver British Columbia Research Council, 1961) During 1960–61 the stations recording marine-borer breeding were increased to more than thirty as more companies engaged the Division of Applied Biology for protecting logs and wooden installations against losses by borers By its larval inspection and log-scheduling service, the Division undertook the protection of more than 100 million feet of timber in sea-water storage for Canadian companies and a similar volume for a company in Puget Sound, where the intensity of marine-borer attack is the highest on the North Pacific Coast.

In instances where serious damage by borers would occur before the logs could be used, the rafts were treated chemically by a sprinkling system developed by the Council During 1960–61 more than 100 sections of high-grade stock were treated in this way prior to hauling from Alaska to Puget Sound, a total of 10 million board feet of wood were chemically treated

One of the outstanding achievements in this field in 1960 was the development of a sonic device for testing the internal condition of pilings This unit accurately reveals even minor damage by borers in piling. The unit has been used for testing the soundness of piling in wharves on Vancouver Island and in Vancouver Harbour Operating in conjunction with a diver, 130 piles a day can be examined

Also developed during the past year was a technique for enshrouding individual piles so that they can be treated chemically to kill embedded borers This method was developed to protect uncreosoted piles which are used in many logging operations on the coast and as fender piles on many wharfs. The shroud is all plastic to avoid corrosion in sea-water, and can readily be clipped on and off a pile without the use of hooks

A number of field studies on *Bankia setacea*, the local teredo-like borer, is being made These include the susceptibility of different species of wood to attack, the rate of loss by different species, the effect of water temperature on breeding, and studies on the borer itself

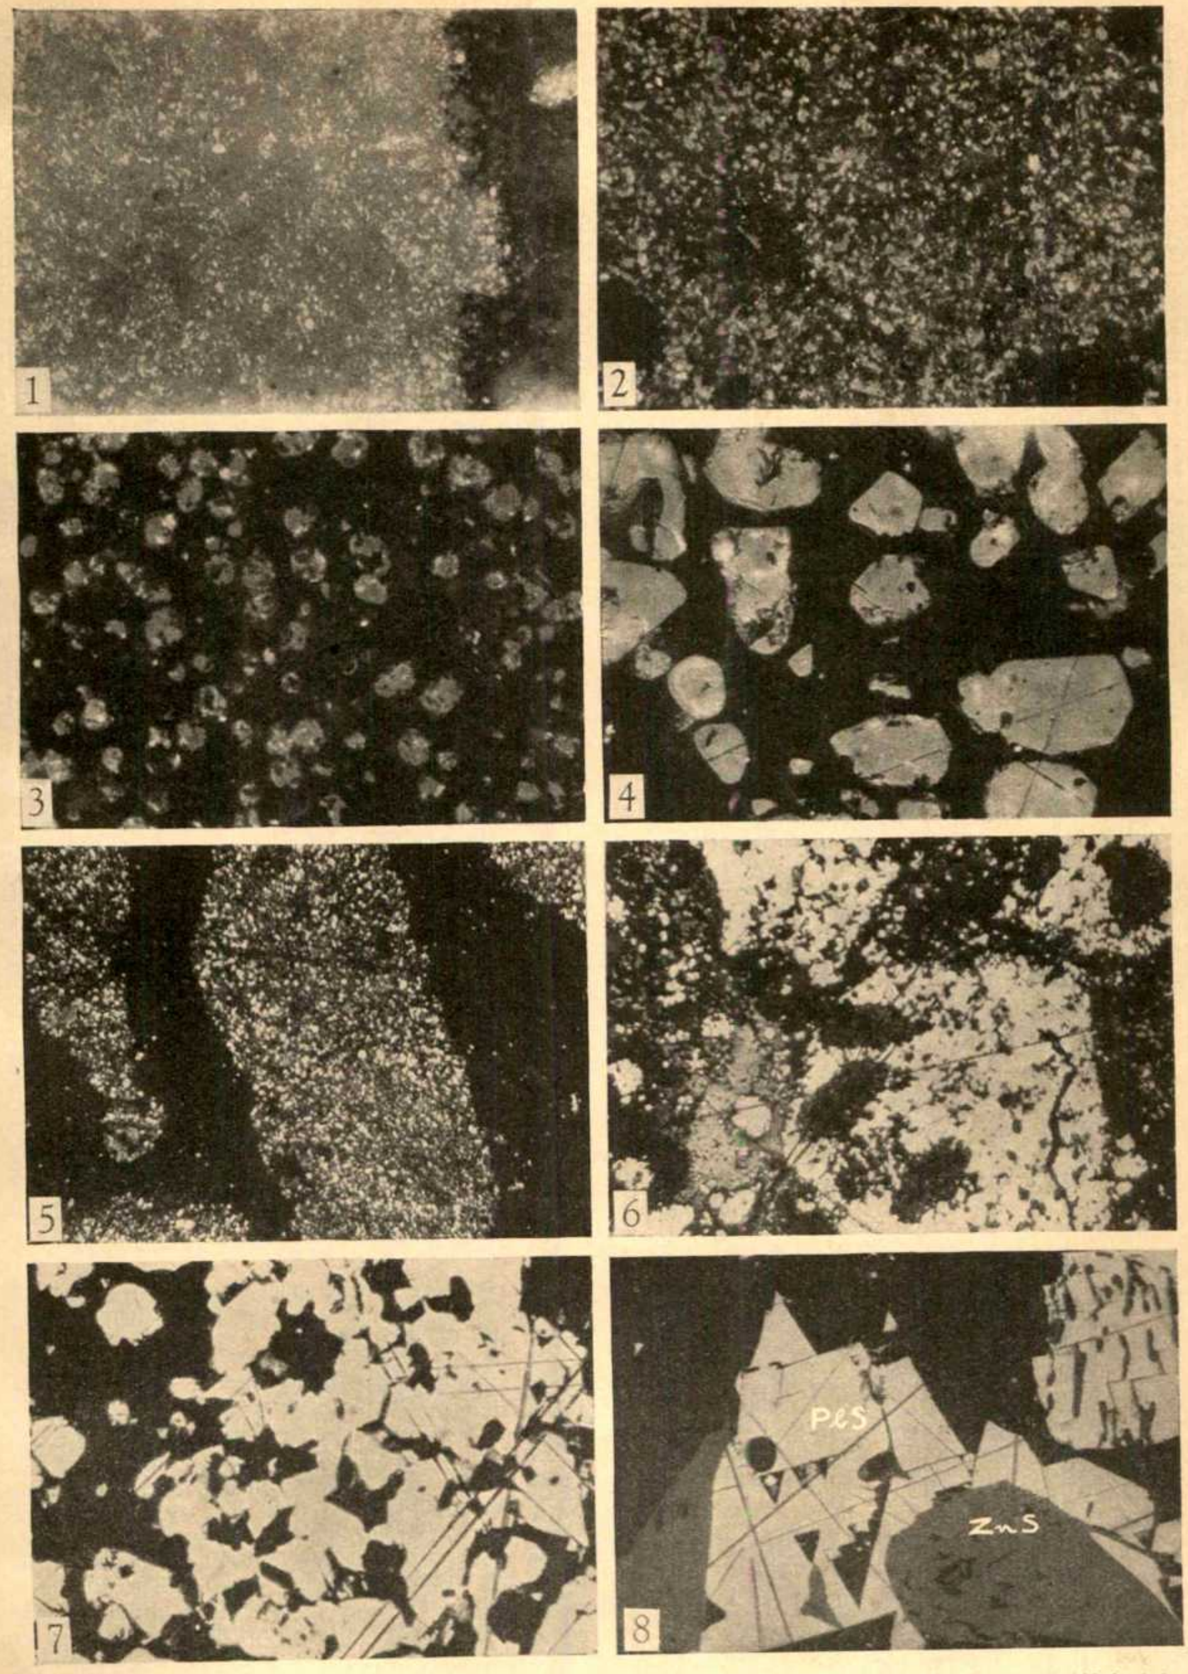
The Canadian Uranium Research Foundation has recently made a grant of 10,000 dollars a year for investigation into the use of uranium compounds as toxicant additives to wood impregnants for marine borers

RECRYSTALLIZATION OF LEAD AND ZINC SULPHIDES

By Dr. J. C. NIXON
Consolidated Zinc Pty Ltd, North Melbourne, Victoria
AND
J D HAYTON, D. C. LAWRIE and A E. TYNAN
Australian Mineral Development Laboratories, Parkside, South Australia

IDEAS advanced in recent years for the formation of conformable ore deposits of base metals (the Broken Hill lead-zinc deposit in New South Wales is one of these) imply that the observed ore textures were developed by crystallization or re-crystallization after initial deposition The earlier ideas depended in part on the assumption that the mineral textures were original and depositional Since a useful understanding of the history of these deposits could be of assistance in exploration, some simple experiments were conducted to find out whether the textural condition of lead and zinc sulphides was or was not affected by temperatures which might be attained in deep burial and in high-rank metamorphism

Chemically precipitated sulphides of lead and zinc were subjected to prolonged treatment in sealed vessels at elevated temperatures The sulphides were prepared by precipitation with hydrogen sulphide from solutions of lead and zinc salts The washed precipitates were dried at 90° C in an inert atmosphere, and stored in a vacuum desiccator Samples of each



Figs. : (1) Zinc sulphide heated at 200° C.; (2) heated at 400° C.; (3) heated at 600° C.; (4) heated at 800° C. (5) Lead sulphide heated at 200° C. ; (6) heated at 400° C. ; (7) heated at 600° C. (8) Zinc sulphide mixture (1 zinc : 1 lead) heated at 800° C. All at magnification 250

sulphide, alone, and with water were heated in a nitrogen atmosphere in stainless steel bombs for 3 weeks at temperatures of 200°, 400° and 600° C. A further sample of each sulphide with water and two mixtures of lead and zinc sulphides and water were heated (in bombs) at 800° C. for 3 days. The molecular ratios of zinc to lead were 1 and 2 in the respective mixtures. The temperature rose above 800° C. for part of the time—perhaps as high as 950°—and the bombs were so badly oxidized after three days that it was considered unsafe to continue heating. The initial sulphides and the materials discharged from the bombs were examined by X-ray diffraction and optical methods.

The X-ray patterns of the initial sulphides had broad peaks, indicating somewhat poor crystallinity. Patterns obtained for both sulphides after treatment at 200° C. for 3 weeks had sharper peaks, showing an improved degree of crystallinity. Materials from subsequent tests at higher temperatures gave diffraction patterns essentially the same as those obtained for the respective sulphides treated at 200° C., indicating that at this stage the materials were sufficiently well crystallized to show maximum sharpness in the diffractograph peaks. Products from heat treatment at temperatures higher than 200° C. were examined optically to determine the degree of crystallization. Optical examination revealed little significant difference between the initial sulphides and those treated at 200° C. In the latter it appeared that re-crystallization had begun in myriads of centres which were less than 1μ across in either sulphide. All these samples consisted of small granules, average size 2–3μ, which were aggregates of particles. Individual grains were detected in the materials heated at 400° C. and a few grains up to 80μ in width were seen in the zinc sulphide heated in the presence of water at this temperature. Some crystal faces were seen on the larger grains of this material. The zinc sulphides heated at 600° C. contained free grains showing no tendency to coalesce. The average particle size was approximately 12μ. The lead sulphides heated at 600° C. contained sintered aggregates of galena. The largest individual particles of galena in both samples were approximately 60μ across.

No really significant difference in resultant particle size was detected between wet and dry treatment. This would indicate that the higher pressures resulting from the presence of water vapour do not have any pronounced effect on the resultant particle size. The zinc sulphide heated at 800° C. for 3 days contained particles up to 90μ in width. The majority were between 30 and 50μ across, and well crystallized. The lead sulphide was reduced to metallic lead at 800° C. There are several possible reactions by which this could occur, but this aspect was not investigated. The lead sulphide in the mixtures was similarly reduced but there were some remnants of galena. In the mixture which contained the higher proportion of lead sulphide (1 zinc : 1 lead) many crystals of both sphalerite and galena were more than 0·5 mm. long and the galena contained numerous blebs of sphalerite typical of a eutectic textural intergrowth. The curved contacts between much of the two minerals were comparable with the mutual boundaries texture found in many natural galena–sphalerite ore bodies. Relatively more of the galena was reduced to metallic lead in the mixture which contained the lesser proportion of lead sulphide (2 zinc : 1 lead). However, the remnants of galena were well crystallized, but of smaller crystal size than in the other sample. The sphalerite was well crystallized and massive, with crystals of the same order of magnitude as in the other mixture.

It is clear that heating lead and zinc sulphides under the conditions described resulted in crystal growth, the effect being more enhanced at higher temperatures. The accompanying photomicrographs of polished sections of the briquetted materials illustrate this trend most effectively.

The work described was done by the Australian Mineral Development Laboratories on behalf of Consolidated Zinc Pty. Ltd.

BIOLUMINESCENCE IN THE SURFACE WATERS OF THE SEA

By RICHARD H. BACKUS, CHARLES S. YENTSCH and ASA WING

Woods Hole Oceanographic Institution, Woods Hole, Massachusetts

RECENT work by Clarke *et al.*[1-4], who have lowered photomultiplier tubes to great depths at sea, have shown that flashing by bioluminescent organisms is present in varying degree at all depths in all localities of the ocean so far examined. Clarke's instrument detects bioluminescence resulting from the combined activities of a variety of organisms and only measures bioluminescence when the ambient light-level is low enough not to mask the flashes.

In order to make observations of bioluminescence independent of ambient light conditions we have devised an apparatus in which water from the sea surface is pumped at the rate of six gallons per minute through a darkened chamber fitted with a photomultiplier tube (*RCA* 6655–*A* with *S*11 spectral response). The tube is connected by appropriate circuiting to a recorder such that organisms luminescing while passing through the chamber are tallied and their numbers recorded at the end of either a 5-min. or a 1-hr. period. The effluent of the chamber may be strained with plankton nets for collecting its fauna and flora.

The plumbing system (Fig. 1) consists of the pump (Jabsco 2187), plastic intake and discharge hoses $\frac{1}{2}$ in. inside diameter, the viewing chamber (where the stream of water is about 2 in. wide and $\frac{1}{4}$ in. deep) and a flow-meter. The length of the intake hose was about 13 ft. in a harbour installation and about 50 ft. in a shipboard installation. In the harbour apparatus it took an organism somewhat more than 1 sec. to pass from the intake to chamber and in the shipborne apparatus about 5 sec. The intake of bioluminescent organisms into the plumbing system stimulates them to flash. Some flash at the point of intake and others all along the hose between intake and chamber. but, as our observations show, many flash in the chamber where the flow pattern is radically altered.

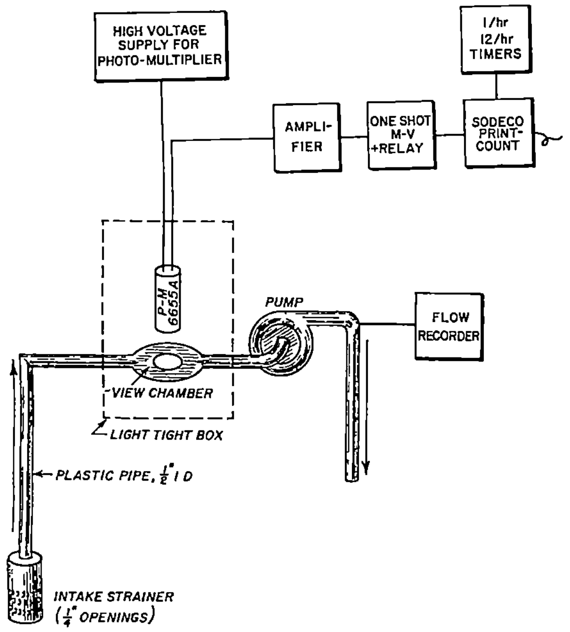


Fig 1

At the shore installation counts were recorded by either a Hewlett–Packard print-out counter (Counter 523 *BN* and Printer 560–*A*) or a Sodeco 1*Tpb*53 print-out counter At sea, counting was done with a simple solenoid-operated Sodeco counter which was read at appropriate times and re-zeroed

Counts of flashes for 1-hr periods for five days each in May and November 1960, in Great Harbor, Woods Hole, are shown in Fig 2 A pronounced diurnal rhythm in activity is obvious In May, maximum, or night-time, counts were about 700 times the minimum, or day-time counts, while in November these differed by a factor of about 100 Details of the rapid increase in count which occurs at sunset are shown in Fig 3 Here counts every 5 min are plotted relative to sunset for two days each in May and November 1960 and show that prior to sunset more bioluminescence occurred in May than November

A No. 20 plankton net was used to strain the effluent for 1½ hr at the time of minimum count and again for the same period at the time of maximum count on December 2, 1960 Counts of the principal groups found and the bioluminescence counts are given in Table 1 The numbers of organisms deemed potential sources of bioluminescence increased at

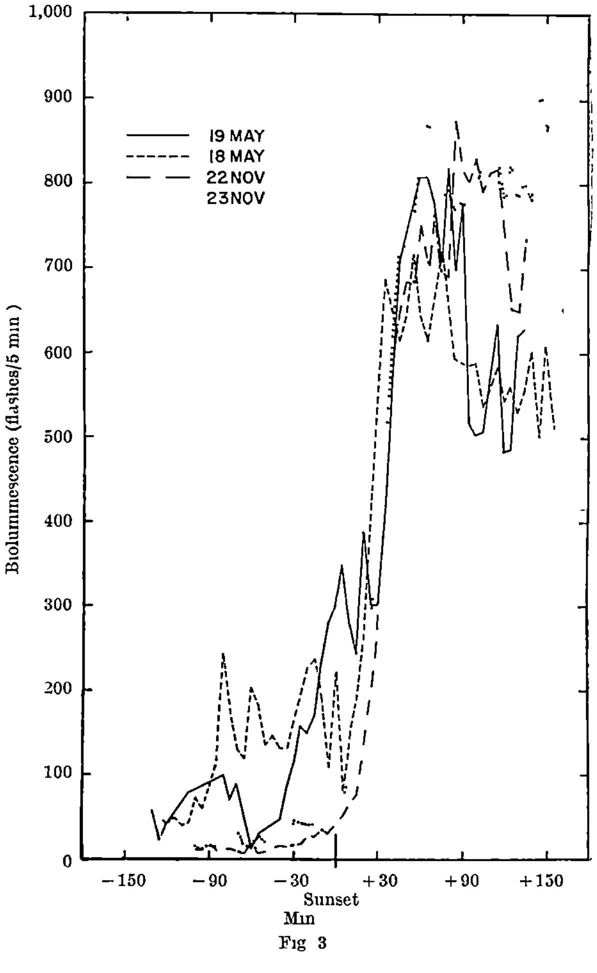

Fig 3

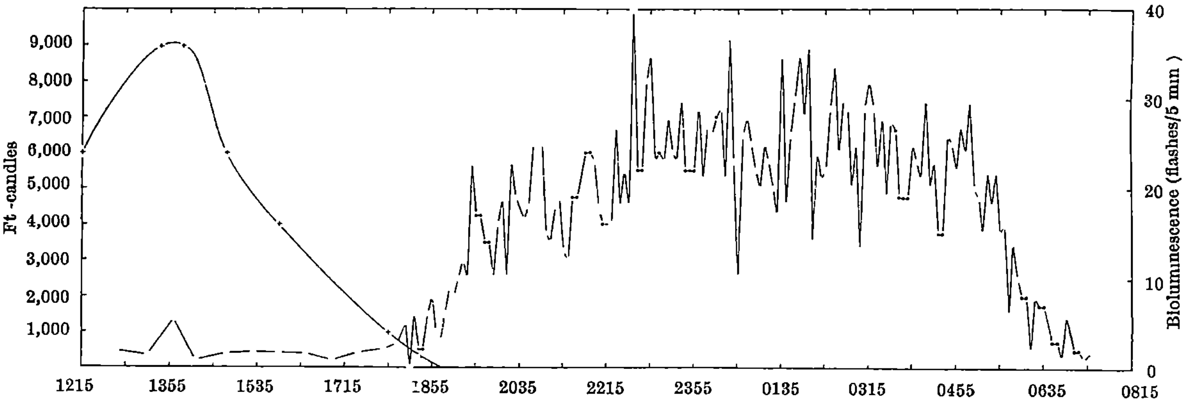

Fig 4

night by factors of about 1 2–5 While a part of the increase in numbers of organisms in the night sample may be due to vertical migration, the species composition was quite different from that during day, which suggests that the water mass changed between sampling times.

Similar observations of bioluminescence were made at eight stations (Table 2) in the continental shelf and slope waters south of New England in September 1960 The plankton community was collected simultaneously by passing the effluent of the pump through a No 20 plankton net Three stations (*A*, *E* and *H*) were occupied for 6–10 hr , including the time of sunset, in order to study the diurnal variation of bioluminescence The other five were used with these three for studying the geographical changes in night-time bioluminescence over the onshore–offshore section

At stations *A*, *E* and *H* a diurnal rhythm in bioluminescence was observed similar to that described for Great Harbor The observations for station *H* are shown in Fig 4 Here, as at stations *A* and *E*, sharp increases in counting-rate were observed when the daylight intensity fell below about 500 foot-candles. This appeared to be true regardless of the magnitude of radiation during the day Bioluminescence counts and counts of the principal organisms found in the effluent at station *H* during the afternoon and evening are shown in Table 3 Even considering the errors that may acrue due to plankton-counting techniques and to the loss of smaller organisms through the net it seems improbable that we would miss a vertical migration of plankton consistent with and of a magnitude sufficient to account for the diurnal changes in bioluminescence observed Results at both stations *A* and *E* were similar

Table 3 BIOLUMINESCENCE COUNTS (HOURLY TOTALS) AND NUMBERS OF ORGANISMS (PER M ³ OF EFFLUENT) AT STATION *H*

Time (E D T)	Bio-luminescence	Diatoms	Dino-flagellates	Green flagellates	Tin-tinnids	Copepods
1400–1500	15	1,600,000	3,063	700,000	396	6,030
1600–1700	16	1,150,000	1,975	300,000	1,088	1,877
1800–1900	46	567,000	2,322	437,000	838	4,440
1900–2000	143	1,475,000	3,510	271,000	811	3,780

Bioluminescence counts, counts of principal plankton organisms and amounts of net and total ('Millipore'-filtered) chlorophyll from the pump effluent during night hours at all stations are given in Table 4 Bioluminescence was at a maximum at *A*, the station nearest the coast, was low across the continental shelf (*B–D*) and rose to an intermediate value at the edge of the shelf (*E*) and remained moderately high at the stations in slope water (*F–H*) Numbers of dinoflagellates (mostly genus *Ceratium*) more or less followed this trend and it is probable that most of the bioluminescence we observed came from these organisms The copepods were more numerous in slope water than at the stations on the shelf, but the cladocerans were present at the shelf stations and absent in the slope water Tintinnids were absent at the shelf stations and present at the slope stations The principal non-luminescent organisms encountered were diatoms They were numerous on the shelf and, in general, diminished seaward except for the large population at station *H* The distribution of total chlorophyll and net chlorophyll was also higher on the shelf than on the slope

It has been our experience that the larger dinoflagellates, which are important producers of bioluminescence, are missed when counts are made on raw sea-water samples of 100–200 ml , thus a fine plankton net had to be used to concentrate these

organisms. We are aware that a great fraction of the phytoplankton passed through the No. 20 net[11]. Comparison of the net to total chlorophyll (Table 4) shows that the net entrained less than 1 per cent of all the photosynthetic autotrophs.

Our observations are consistent with certain observations (summarized by Harvey[8]) of bioluminescence in sea-water samples containing dinoflagellates held under various conditions of light and dark, and with recent observations of circadian rhythms of bioluminescence in laboratory cultures of dinoflagellates[9,10].

Seliger, Fastie and McElroy[7] have recently published observations of bioluminescence in Chesapeake Bay using an instrument which integrates light intensity over short periods rather than counting flashes. They observed no diurnal rhythm and concluded that changes in intensity throughout the water column were due to the vertical migration of organisms. In contrast, we feel that the diurnal pattern of bioluminescence observed by us largely results from the inactivation of the bioluminescent system of the organisms responsible by daylight. The discrepancy between the Chesapeake Bay and Woods Hole results may be due in part to the difference in instruments but more than likely comes mainly from the geographical difference.

RESERPINE-INDUCED CIRCULATORY FAILURE

By Prof. ELEANOR ZAIMIS

Department of Pharmacology, Royal Free Hospital School of Medicine, London, W.C.1

DURING work on various drugs affecting adrenergic mechanisms, the first results of which have already been published[1], it was found that 24 hr. after the administration of 1 mgm./kgm. of reserpine a good number of cats, despite all care, died. Those animals which survived were very ill, lay immobile, unresponsive to sound, apparently lifeless. When handled and gently caressed, however, they opened their eyes and, with great difficulty although not paralysed, succeeded in making some movements, while purring and yet crying simultaneously. Despite all precautions, body temperature tended to fall, respiration was depressed, blood pressure was very low and the heart-rate markedly reduced. There was a loss of body-weight, possibly because the animal neither ate nor drank and, in addition, suffered marked diarrhœa. In other words, cats thus treated were very sick animals and presented a picture of great misery very similar in many ways to that of a human being during a stage of advanced shock (for example, late stages of acute circulatory failure), and definitely very much unlike the picture of an animal under the influence of an ordinary central depressant drug.

Reserpine is known to reduce or deplete the various tissues of their catecholamine content, and its pharmacological actions, especially those on circulation, have been, as a rule, attributed to this depletion[2]. Because of this, the cardiovascular system of animals pretreated with reserpine or isolated tissues from these animals have been extensively used for the study of the mechanism of action of various drugs. The cat has been a favourite experimental animal and, in order to 'reserpinize' it, doses of at least 1 mgm./kgm. of the drug have usually been used. The severe clinical condition, however, of the cats treated with reserpine was considered unlikely to be the result only of a depletion, however complete, of the animal's catecholamines. Experiments were therefore undertaken in which various parts of the cardiovascular system could be studied simultaneously *in vivo*.

Most cats were given a single dose of 1 mgm./kgm. of reserpine, either subcutaneously or intraperitoneally, on the day before the experiment. A few received the same amount of the drug spread over two or more days. Both the control and the reserpine-treated animals were anæsthetized with chloralose and prepared for the recording of blood pressure, peripheral blood flow (measured by recording the venous outflow from a hind limb) and force of cardiac contraction (recorded by means of a strain gauge arch attached directly to the muscle of either the right or the left ventricle).

The blood pressure of the cat pretreated with 1 mgm./kgm. of reserpine was low, rarely exceeding 70 and very often less than 50 mm. mercury and the heart-rate very slow. When the chest was opened, the heart was found to be enlarged, flabby and soft and the superior and inferior venæ cavæ and their tributaries engorged. The right side of the heart was, as a rule, at this stage more affected than the left. Moreover, the force of cardiac contraction was well below normal and the application of pharmacological tests clearly demonstrated that the heart was in failure. Furthermore, it was found that: (*a*) the sensitivity of the peripheral vessels to adrenaline, noradrenaline and isoprenaline, administered intravenously or close-arterially, was decreased; (*b*) any changes of blood pressure were, as a rule, secondary to changes in cardiac contraction; and (*c*) the peripheral blood flow passively followed the changes of blood pressure. In other words, 24 hr. after the administration of 1 mgm./kgm. of reserpine the cat exhibited a most spectacular circulatory failure, and furthermore any improvement of the circulation at this stage was found to be almost exclusively the result of an amelioration of the force of cardiac contraction.

Although circulatory failure was always present, its degree varied from animal to animal. For example, in older, lactating or pregnant animals the condition was at its worst. When the heart failure was less advanced, the force of cardiac contraction increased after the administration of adrenaline, noradrenaline or isoprenaline. However, as a rule, noradrenaline produced the largest inotropic effect, adrenaline was less effective, followed by isoprenaline. Moreover, in a number of experiments the force of cardiac contraction after isoprenaline was either unaffected or clearly depressed. Thus, in the animals treated with reserpine the ratio appeared quite different from that in the control cats, where isoprenaline is the most powerful of the three catecholamines. The reason for this rather puzzling behaviour of the catecholamines in the animal treated with reserpine became apparent when changes of heart-rate were recorded at the same time. It was found that the heart of the animal treated with reserpine, in contrast to the control, was unable to sustain an increased activity. Consequently, its response to isoprenaline varied according to its condition at the moment of the administration of the drug; if very poor, the heart faced the abrupt increase in heart-rate with a clear-cut depression in the force of its contraction; on the other hand, when failure was not very advanced, the heart contraction could still improve, but even then the response was always much smaller than that usually seen in the control heart. A similar variation, although less pronounced, was found with adrenaline. In the majority of experiments, adrenaline did produce a positive inotropic effect. Occasionally, however, when heart failure was very advanced, the effect of adrenaline on the heart was depressant. The only catecholamine the administration of which was always followed by a positive inotropic effect was noradrenaline.

In control cats a dose of 50–100 μgm. of ouabain produced very little or no change at all in either the force of cardiac contraction or the blood pressure. In contrast, in the animals treated with reserpine after ouabain, a gradual increase in the amplitude of the cardiac contraction occurred accompanied by a simultaneous rise in blood pressure. Furthermore, ouabain was found partially to restore the positive inotropic effect of various drugs, which in the animals treated with reserpine became ineffective or depressant to the heart. This was the case with both tyramine and isoprenaline.

Furthermore, histological examination of the heart muscle revealed in each case extremely severe and widespread degenerative changes (Fig. 1). The examination of various other organs is still in progress. However, the results already obtained indicate that the liver undergoes, at this stage, centrilobular (fatty) changes indicative of heart failure and raised venous pressure. Moreover, while the adrenal medulla appeared normal, the cortex in most animals showed a picture characteristic of severe stress with widespread degenerative changes affecting the cells of both zonæ fastigiata and fasciculata.

From these results it is quite obvious that, in the cat, reserpine in a dose of 1 mgm./kgm. produces a most spectacular poisoning of the heart muscle, leading rapidly to disastrous functional impairment. As the myocardium is of the very essence in the maintenance of the circulation, all other factors which contribute to the circulation of the blood, although important, are likely to be secondary to the function and integrity of the heart muscle. However, the reduced sensitivity of the peripheral vessels of these animals to the normal mediators must undoubtedly contribute to the circulatory debacle which develops in such an incredibly short period of time.

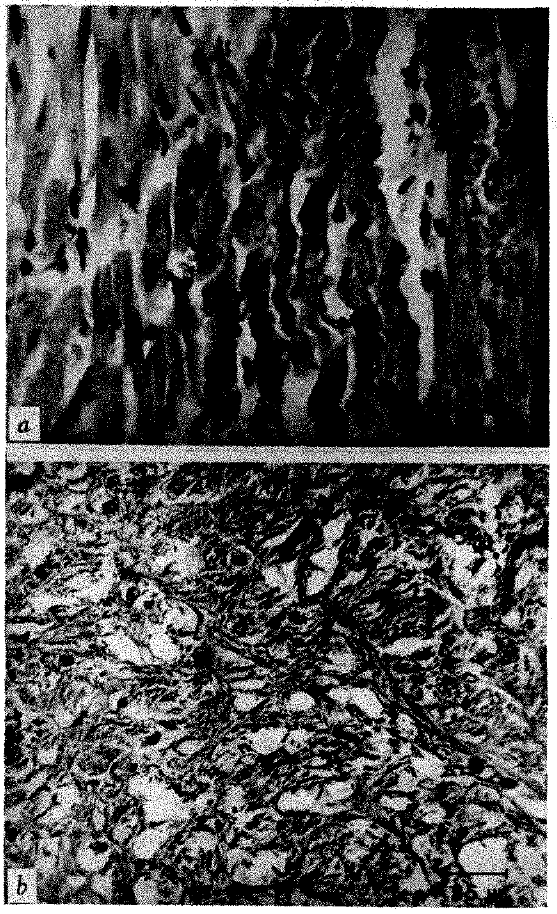

Fig. 1. Photomicrograph of myocardium (hæmatoxylin and eosin): (a) from a control cat; (b) from a cat treated with reserpine (0·25 mgm. per kgm. for 5 days)

The function and histological abnormalities found in the other organs of the animals treated with reserpine may be due to either direct toxic effects or to changes secondary to tissue anoxia, bound to exist in an acute circulatory failure.

The mechanism by which reserpine produces such powerful toxic effects remains to be elucidated. However, the functional and histological changes on one hand and the finding on the other hand that a metabolically 'active' tissue is more affected than a tissue relatively 'at rest' strongly suggest that the drug inhibits either some energy-yielding or some energy-consuming reaction. Kirpekar and Lewis[3] and Gillis[4] have already suggested a depressant effect of reserpine on the oxidative metabolism of various tissues.

Evidence that reserpine is a highly toxic drug has been previously reported. Unfortunately, such evidence has not received the attention it deserved. Saffran and Vogt[5] found that in rats a single intraperitoneal injection of reserpine (2·5 mgm./kgm.) produced a fall in the concentration of corticotrophin of the pituitary to 30 per cent of the resting value The authors reached the conclusion that this effect of reserpine is not due to interference with storage of adrenocorticotrophic hormone in the tissue, but was simply the result of the drug acting as a stressing agent In their experiments, the losses in adrenocorticotrophic hormone were of a degree not previously encountered after the injection of drugs, but of the magnitude reported after adrenalectomy, or after removal of one and enucleation of the other adrenal The only substance which in Saffran and Vogt's hands caused an even greater loss of adrenocorticotrophic hormone was a severely toxic drug—a nitrogen mustard, 24 hr after the injection of di(2-chloroethyl) methylamine hydrochloride ('Mustine', Boots) the rats which had survived exhibited œdema and weakness and the corticotrophin of the pituitary had fallen to 10 per cent

Goldin *et al* [6] have reported that reserpine exerts an anti-tumour effect They demonstrated that treatment with reserpine produced a significant increase in the survival-time of mice carrying advanced lymphoid leukæmia (*L* 1210) and caused regression of the local tumour which develops at the site of inoculation Robison *et al* [7] have made similar observations Furthermore, West *et al* [8] demonstrated that reserpine, in small doses, inhibited the growth of three different tumours in mice, and decreased uptake of oxygen in the intact animal They reached the conclusion, however, that the anti-tumour effect of reserpine is mostly non-specific and dependent on depression and reduction of food intake

Reserpine appears thus to be one of the most powerful 'poisons' known in pharmacology, and the 'reserpinized' animal, with both central and peripheral circulation in acute failure, a most abnormal experimental tool

I am grateful to my colleagues, Drs P P and M G Scott and Elizabeth Davis for their valuable advice and help with the histological studies This investigation was supported by a grant from the Palissade Foundation, Inc , of New York, and grant *B*-2474 (*C*1) from the National Heart Institute, National Institutes of Health, U S Public Health Service

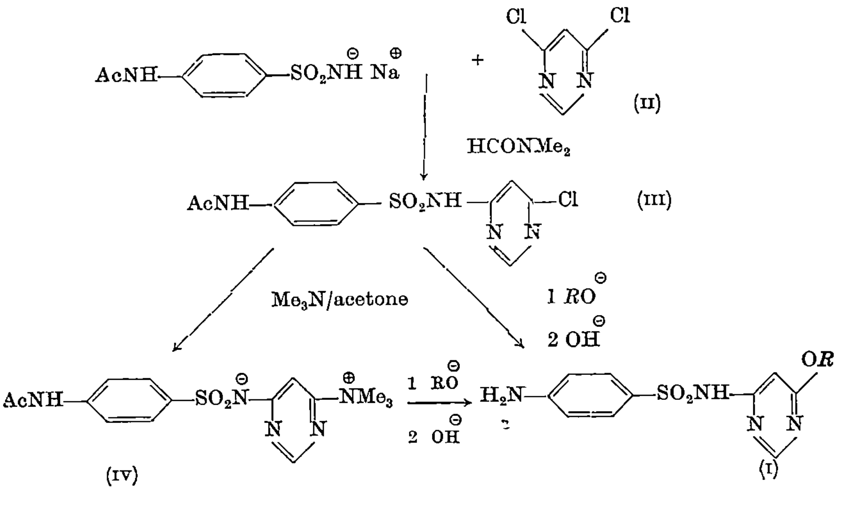
4-SULPHANILAMIDO-6-METHOXY AND 6-ETHOXY PYRIMIDINE (I.C.I. NOS. 32,525 AND 33,536): TWO NEW LONG-ACTING SULPHONAMIDES

By Dr R CLARKSON and Dr. A R. MARTIN

Imperial Chemical Industries, Ltd , Pharmaceuticals Division, Alderley Park, Macclesfield

RENEWED activity in the sulphonamide field over the past few years has been aimed primarily at compounds with prolonged action The first compound with this characteristic, 2-sulphanilamido-4,6-dimethoxypyrimidine, was synthesized in these laboratories in 1947 (ref 1), and illustrated the importance of the methoxyl group in lowering the rate of excretion Sulphamethoxypyridazine[2] and sulphadimethoxine[3] followed from the laboratories of American Cyanamid and Hoffmann–La Roche and have attained wide clinical use

The one compound, closely related to these, which had not been prepared previously, was 4-sulphanilamido-6-methoxypyrimidine (I, *R* = Me) This and analogous compounds were readily available by the following route, starting with 4,6-dichloropyrimidine II (ref 4)



The zwitter-ionic trimethylammonium compound (IV) proved to be a useful intermediate in the preparation of higher homologues (compare ref. 5) since it is much more reactive to nucleophilic reagents than is the chloro-compound (III). 4,6-Dichloropyrimidine (II) reacts smoothly with ethanolic ammonia at room temperature to give 4-amino-6-chloropyrimidine. Replacement of the 6-chlorine with alkoxide followed by the standard sulphonylation procedure yielded I. The experimental details of these reactions have already been published[6]. The synthesis of the methoxy compound by similar routes was afterwards published by the American Cyanamid workers[7].

The 6-methoxy (32,525) and 6-ethoxy (33,536) sulphonamides are of outstanding efficacy against experimental infections in mice, as shown here, but this effect falls off as the size of the alkoxy group increases, presumably because of poor absorption from the gastro-intestinal tract. Substitution in the 5-position of the pyrimidine ring also lowered the antibacterial effect in most cases[8].

The antibacterial action *in vivo* and *in vitro* of 32,525 and 33,536 is compared here against three most widely used, long-acting sulphonamides. The effect of sulphaphenazole[9] against an experimental *Streptococcus pyogenes* infection was so poor that this compound was not included in further comparisons. The three organisms used in this work, both *in vivo* and *in vitro*, were *Salmonella dublin*, *Streptococcus pyogenes* (strain Kruger) and *Staphylococcus aureus* (strain Buttle 147).

Bacteriostatic action in vitro. Median inhibitory concentration of the sulphonamides mentioned were determined in Jewell and Pearmain's medium[10] (median inhibitory concentrations are expressed in µgm./ml. and are the mean of three concordant observations, determined graphically), they are shown in Table 1.

Table 1

Sulphonamide	Test organism *Strep. pyogenes*	 *Staph. aureus*	 *Sal. dublin*
32,525	13	3	5
33,536	19	3	15
Sulphadimethoxine	6	3·5	64
Sulphamethoxypyridazine	42	14	14
Sulphaphenazole	12	6	60

The results given in Table 1 show that 32,525 is as effective as the other compounds against the Gram-positive organisms and clearly illustrates its superiority against the Gram-negative.

Therapeutic action in vivo. Infected mice were treated orally with the sulphonamides, doses being given 1 hr. after the infection with subsequent doses at 24 and 48 hr. Deaths were recorded daily, mice alive on the eighth day (fifteenth in the *Staph. aureus* infection) being arbitrarily awarded a survival time of 8 (or 15) days. The figures given in Tables 2, 3 and 4 are 'effects', that is, mean survival time in days of the treated group minus mean survival time of the control group.

Table 2. *Streptococcus pyogenes*

Compound	Dose (mgm./20 gm.) 8	 4	 2	 1	 0·5
32,525	5·0	3·3	2·6	1·1	0·7
33,536	4·9	4·5	3·6	1·6	0·6
Sulphadimethoxine	3·7	1·2	0·4	0·2	0·0
Sulphamethoxypyridazine	3·8	2·3	1·8	0·6	0·2
Sulphaphenazole	1·9	0·4	0·2	0·0	0·0

Table 3. *Salmonella dublin*

Compound	Dose (mgm./20 gm.) 0·5	 0·25	 0·125	 0·06	 0·03	 0·015
32,525	5·5	5·0	4·8	3·5	2·3	2·0
33,536	5·1	4·9	3·9	2·6	2·1	0·9
Sulphadimethoxine	2·9	2·3	0·7	0·0	0·9	—
Sulphamethylpyridazine	3·0	2·6	1·4	1·6	0·9	—

Table 4. *Staphylococcus aureus*

Compound	Dose (mgm./20 gm.) 0·5	 0·25	 0·125	 0·06	 0·03
32,525	12·5	11·1	8·5	4·7	1·0
33,536	10·9	10·9	2·7	1·4	—
Sulphadimethoxine	7·8	3·6	—	—	—
Sulphamethylpyridazine	10·9	2·1	1·3	0·0	—

It can be demonstrated that the fraction of a sulphonamide which is bound to plasma proteins has no antibacterial activity[11]. Equilibrium dialysis experiments between buffer and human (or mouse) plasma show that the two new compounds are less extensively bound than the older ones. This fact, together with the high intrinsic activity and a persistence in the mouse about equal to that of sulphamethoxypyridazine, probably explains the superior effect of 32,525 and 33,536.

GROUP RETENTION FACTORS IN THE GAS-LIQUID CHROMATOGRAPHY OF STEROIDS

By R. B. CLAYTON

Conant Chemical Laboratories, Harvard University

IT has been shown[1] that the retention time of a mono-unsaturated sterol methyl ether on the gas-liquid chromatogram, in which polyethylene glycol succinate is the liquid phase, may be expressed in the form

$$r_{(s+x)} = r_s \times k_x \qquad (1)$$

where $r_{(s+x)}$ is the retention time of the sterol having a double bond in position x, r_s is the retention time of the parent saturated structure and k_x is a constant factor, characteristic of the position of the double bond but independent of the molecular weight. The further relationship

$$r_{(s+x+y)} = r_s \times k_x \times k_y \qquad (2)$$

describes the retention time, $r_{(s+x+y)}$ of a dienol methyl ether with non-interacting double bonds in positions x and y, the second double bond being characterized by the factor k_y

These observations suggest that this type of relationship is a general one such that the introduction of a substituent group into a specific position in the steroid molecule influences the retention time by a factor which is a constant for the type of grouping and its particular site of attachment, but which is independent of the molecular weight of the total structure and of the influence of other functional groups, provided no interactions occur with them

If this is so, it is to be expected that equation (2) may be applied in its most general form to the steroids, so that the retention time of a poly-substituted steroid in which intramolecular group interactions are negligible can be expressed as

$$r_{(n+a+b+c+\ldots)} = r_n \times k_a \times k_b \times k_c \times \ldots \qquad (3)$$

where $r_{(n+a+b+c+\ldots)}$ is the retention time of the total structure, r_n is the retention time of the unsubstituted nucleus and $k_{a,b,c,}$ are group retention factors for a series of non-interacting substituents at positions a, b, c, etc It is the purpose of this communication to present the preliminary results of some work with compounds which have been selected with the specific object of testing equation (3)

The steroids were authentic samples which had been synthesized by standard methods Methyl ethers were prepared by reaction of the appropriate hydroxy-compounds with methyl iodide in the presence of potassium *t*-butoxide in diethyl ether Gas-liquid chromatography was carried out with 5 per cent polyethylene glycol succinate as the liquid phase under conditions exactly as previously described[1]

The retention times, relative to that of cholestane, of a series of steroid hydrocarbons, their 3β-methoxy-, 3β-methoxy-Δ^5-, and 5α-hydroxy-derivatives are presented in Table 1 In the last three columns of Table 1 are listed the retention factors for the 3β-methoxyl and 5α-hydroxyl groups and the Δ^5-bond, respectively These are the separation factors between the saturated parent hydrocarbons and their corresponding 3β-methoxy- and 5α-hydroxy-derivatives and between the saturated 3β-methoxy-compounds and their Δ^5-derivatives.

The retention factor for the 3β-methoxyl group in the saturated series is seen to be the same, within the limits of measurement, in all cases The factor associated with the introduction of the Δ^5 bond into the 3β-methoxy-compounds, which has already been shown to be constant for the C_{27}, C_{28} and C_{29} sterols[1], is seen from the present work to have the same value in the C_{19} and C_{21} series The retention factor of the 5α-hydroxyl group shows greater variation than can be accounted for by operational error but still remains constant over a range of 4 per cent as between the pregnane and stigmastane derivatives

Table 1 RELATIVE RETENTION TIMES OF SOME STEROID HYDROCARBONS AND DERIVATIVES

	Substituents			Retention factors		
Hydrocarbon	3β-methoxyl	5α-hydroxyl	3β-methoxy-Δ^5	3β-methoxyl	5α-hydroxyl	Δ^5
Androstane 0 12	0 42	—	0 461	3 55	—	1 09
Allopregnane 0 21	0 73	1 10	0 806	3 50	5 25	1 10
Cholestane 1 00	3 50	5 24	3 80	3 50	5 24	1 09
Ergostane 1 38	4 89	6 98	5 22	3 54	5 06	1 07
Stigmastane 1 72	6 11	8 70	6 60	3 55	5 06	1 08

Table 2 presents some results obtained with a series of bifunctional steroids, chosen to test the accuracy with which retention times may be predicted by means of equation (3) In the left-hand side of the table are listed a series of monofunctional compounds and their retention times relative to that of cholestane In the right-hand side a series of bifunctional derivatives are listed, together with their observed relative retention times and their calculated relative retention times derived from the data for the monofunctional steroids in the left-hand side of Table 2 and the appropriate values shown in Table 1 It is seen that in all except the last two cases (5α-hydroxy-Δ^2-cholestene and 5α-hydroxy-Δ^7-ergostene) there is close agreement (within 4 per cent) between the observed and calculated values

Table 2 OBSERVED AND CALCULATED RELATIVE RETENTION TIMES (r) OF SOME MONO- AND BI-FUNCTIONAL STEROIDS

Monofunctional steroids		Bifunctional steroids		
	r (obs)		r (obs)	r (calc)
17β-Methoxyandrostane	0 333	3β,17β-Dimethoxy-androstane	1 19	1 18
7α-Methoxycholestane	1 67	3β,7α-Dimethoxy-cholestane	5 65	5 83
7β-Methoxycholestane	2 25	3β,7β-Dimethoxy-cholestane	7 65	7 88
		3β,7α-Dimethoxy-allopregnane	1 19	1 22
		3β,7β-Dimethoxy-allopregnane	1 60	1 64
7α-Hydroxycholestane	6 83	3β-Methoxy-7α-hydroxy-allopregnane	5 20	5 00
Δ^2-Cholestene	1 20	5α-Hydroxy-Δ^2-cholestene	5 34	6 30
Δ^7-Ergostene	1 80	5α-Hydroxy-Δ^7-ergostene	7 26	9 06

The aberrant results obtained in the case of unsaturated 5α-hydroxy-compounds bear on the question of intramolecular group interactions The calculated values for the relative retention times of 5α-hydroxy-Δ^2-cholestene and 5α-hydroxy-Δ^7-ergostene exceed the observed values by 18 and 25 per cent respectively Measurements of Dreiding models indicate that the approximate distances of 3 1 and 2 9 Å between the 5α-oxygen atom and C_2 and C_3 respectively in the Δ^2-compounds are almost identical with the distances between the oxygen atom and C_8 and C_7 in the Δ^7-compound It is therefore reasonable that approximately the same degree of interaction should take place between the double bond and the homoallylic hydroxyl group in each case The precise nature of the interaction is not clear It may be in part a simple steric effect in which the hydroxyl group partially blocks the interaction between the double bond and the liquid phase but probably also involves a transannular π-bonded interaction between the double bond and the labile hydroxylic hydrogen. An evaluation of the relative importance of these two possible effects would require a study of analogues in which the 5α-hydroxyl group was replaced by an inert substituent of similar size

These results attest to the validity of equation (3) as a general expression of the relationship between structure and retention time in the steroid series. They are entirely consistent with the relationships between members of the same and closely related homologous series which have already been firmly established by the work of James and others[2]. It has been in the nature of the materials which have been most thoroughly investigated hitherto that emphasis has fallen more heavily on the logarithmic relationship between retention time and molecular weight within a homologous series than on these separation factors between different homologous series. In the present context the retention factors arising from the introduction of individual substituent groups into the molecule inevitably claim complete attention

As was pointed out previously[1], the precise influence of the liquid phase on the values of the group retention factors remains to be established. Lipsky and Landowne, in a valuable summary[3] of separations achieved with a wide range of steroids on a variety of the less polar polyester liquid phases, have reported separation factors which are approximately of the same relative order as those obtained in these Laboratories. Similar results have also been reported by Haahti *et al* [4]. It seems likely that the same general relationship expressed in equation (3) must hold with the less polar liquid phases but that the actual values of the group retention factors differ considerably according to the chemical nature of the liquid phase In view of the generally shorter retention times obtaining with the less polar polyester liquid phases used by the above authors it is evident that these are to be preferred for the separation of highly oxygenated compounds since the cumulative effects of highly polar substituents soon lead to excessive retention times For the analytical separation of simple sterols, in the form of their methyl ethers, however, there may well be some advantage in the use of the highly polar polyglycol succinate used in the present work

The extension and further refinement of this type of study seem likely to yield information which will supplement in a novel manner the existing body of knowledge concerning reactivity of substituent groups and their intramolecular interactions The practical value of the group retention factor method for the elucidation of hitherto unknown steroid structures is already established by its routine use in these Laboratories

A complete account of this and related work will be presented elsewhere. I wish to express my thanks of Prof Louis Fieser and Prof H B Henbest for generous gifts of steroid samples and to Prof Konrad Bloch for his interest

This investigation was carried out during tenure of an established investigatorship of the American Heart Association and was supported by grants from the American Heart Association and the National Institutes of Health

SURVIVAL OF *RHIZOBIUM* ON CLOVER SEEDS

By J. F LONERAGAN*, D V. MOYE and A. J ANDERSON

Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization, Canberra

THE high death-rate of *Rhizobium* inoculated on the surface of clover seeds is a serious problem where the survival of adequate numbers of rhizobia on the seed is essential for satisfactory nodulation, as in acid soils where the acidity further reduces the number of viable rhizobia[1] On lime-coated seed, which is used for establishing legumes on acid soils[2], the death-rate is also high[3] and in addition the seed is difficult to re-inoculate This article reports the survival of *Rhizobium* on seeds of subterranean clover for periods exceeding twelve months, in the presence or absence of a lime coat

A treatment designed to force rhizobia under the seed coat[4] was tested in experiments with the Mount Barker strain of subterranean clover (*Trifolium subterraneum* L) The method used was to immerse the seeds in a liquid culture of *Rhizobium*, and apply a vacuum of 700 mm of mercury for three successive periods The total period of immersion was 5 min

Rhizobium trifolii strain *NA*30 was cultured in a yeast mannitol medium[5] of *p*H 7 Immediately prior to inoculation, maltose or sucrose was added to the culture (nodulation was not affected by the form of sugar) to give a concentration of 10 per cent sugar Solutions containing 10 per cent sugar were used for all dilutions and for the uninoculated controls One set of replicates was prepared without a lime coat, and a corresponding set with a lime coat, using 50 mgm of methyl ethyl cellulose[6] plus 5 gm of precipitated calcium carbonate per 25 gm of clover seed The seeds were air-dried and stored in paper envelopes at room temperature, which seldom varied outside the range of 20°–27° C

Two lots of seed which had been prepared separately (Exps. 1 and 2, Table 1) were sown on an agar medium of *p*H 7 in test-tubes 64 weeks after treatment There were twelve tubes per treatment, with two seeds in each tube Table 1 shows clearly that the use of the immersion and vacuum treatment enabled rhizobia to survive on a proportion of the seeds for 64 weeks, and that lime-coating the seeds had no harmful effect on this survival

The results presented in Fig 1 show the beneficial effects of the immersion and vacuum treatment in

Table 1 NODULATION OF SUBTERRANEAN CLOVER SOWN ON AN AGAR MEDIUM 64 WEEKS AFTER TREATMENT

Inoculation treatment		Percentage of tubes with nodulated plants	
Method	No of rhizobia per ml of inoculum*	Without lime coat	With lime coat
	Experiment 1		
Uninoculated	0	0	0
Normal	$2\ 2 \times 10^{7}$	0	0
Immersion and vacuum	$2\ 2 \times 10^{6}$	8	17
Immersion and vacuum	$2\ 2 \times 10^{8}$	17	17
	Experiment 2		
Uninoculated	0	0	0
Normal	$2\ 4 \times 10^{8}$	0	0
Immersion and vacuum	$2\ 4 \times 10^{6}$	25	17
Immersion and vacuum	$2\ 4 \times 10^{9}$	42	42

* For the normal inoculation treatment, 1 ml of inoculum was added to 25 gm of seed (approximately 3,000 seeds) For the immersion and vacuum treatment 25 gm of seed absorbed about 3 ml of inoculum

---

* Present address Institute of Agriculture, University of Western Australia, Nedlands, Western Australia

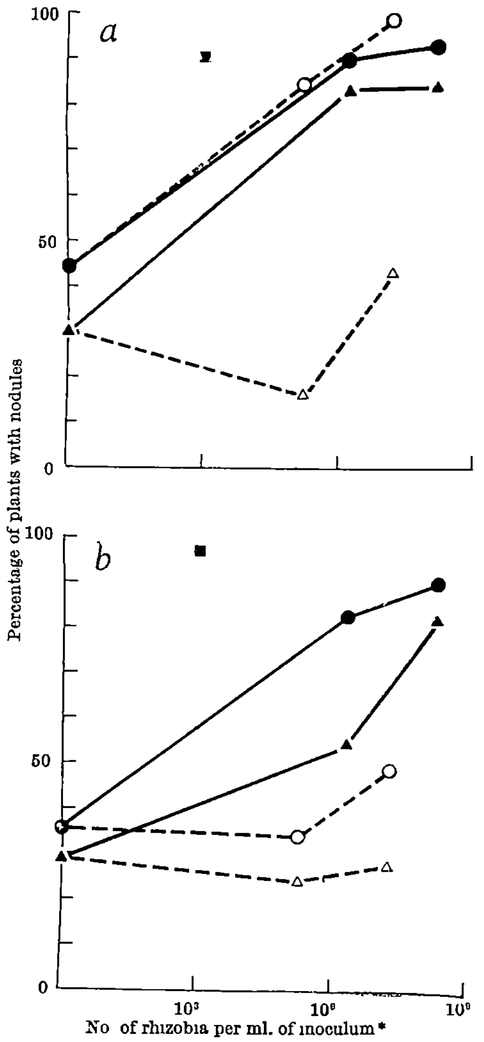

Fig. 1 Effects of treatments on the nodulation of subterranean clover sown on an acid soil in the field *a*, 1 day, *b*, 12 weeks after inoculation △, normal inoculation, ○, normal inoculation, with lime coat, ▲, immersion and vacuum inoculation, ●, immersion and vacuum inoculation, with lime coat, ■, freshly inoculated, drilled with lime * See corresponding footnote to Table 1

field sowings on a virgin soil of *p*H 5 4 The normal method of inoculation was ineffective on this soil when used without a lime coating, even when the seeds were sown one day after inoculation When the seeds were lime-coated the normal method of inoculation was effective for the first sowing, but was not effective after storage for twelve weeks When the seeds were immersed in *Rhizobium* inoculum and subjected to vacuum, the inoculation was effective at both sowings At the twelve-week sowing the highest percentage nodulation occurred where freshly inoculated seed was drilled with lime, but pre-inoculation by immersion and vacuum treatment combined with lime coating was nearly as good

At the first field sowing (Fig 1) there was a good response to inoculation by the immersion and vacuum treatment in the absence of a lime coat, suggesting that this method of inoculation had provided the *Rhizobium* with some protection against the harmful effects of the acid soil The response was also evident at the twelve-week sowing, although here a lime coat was needed for the best response to inoculation where the lower number of rhizobia was used

Further tests were made in an acid soil in a glass-house All the treatments shown in Fig 1 were included in a trial in pots sown 32 weeks after the treatment of the seed In this trial the only response to inoculation was obtained where the immersion and vacuum treatment was used in conjunction with a lime coat on the seed The lime-coated, vacuum-inoculated seed gave 75 per cent nodulated plants at each level of inoculation, compared with less than 20 per cent of nodulated plants for all other treatments

At a 52-week sowing in pots, where the immersion and vacuum treatment was tested only in the presence of a lime coat, the lower and higher levels of inoculation respectively gave 16 per cent and 51 per cent nodulated plants, compared with no nodules on the uninoculated controls

These results show that it is possible to inoculate clover seeds in a way that enables the rhizobia to survive for very long periods It is clearly important to define the factors concerned in the effect of the immersion and vacuum treatment used, and in the survival of the rhizobia

CHOLINERGIC NEURONS IN VERTEBRATES

By Dr. CATHERINE HEBB

Agricultural Research Council Institute of Animal Physiology, Babraham, Cambridge

CAVANAGH and Holland[1] have recently reported histochemical evidence showing that acetylcholinesterase (AChE) is more widely distributed in the nervous system of the chicken than in the nervous system of mammals They found that in the hen, in contrast to mammals, it was present in the cytoplasm of all central neurons examined and was in the dorsal root ganglion cells as well Because cholinergic cells characteristically contain AChE (ref 2), they suggest that all neurons in this species are cholinergic and that in this respect it differs fundamentally from mammals, in which non-cholinergic as well as cholinergic cells are found The additional possibility is adumbrated that an all-cholinergic nervous system is simpler than one to which non-cholinergic cells contribute and as such may be better suited to the requirements of a species less highly developed than mammals I would like to comment on these suggestions in the light of earlier published work[2] and of evidence which I have been collecting, as material becomes available, on acetylcholine (ACh) metabolism in representative vertebrate species This later work, which is referred to here, has been briefly summarized in an article now in the press[3]

First. it is relevant to consider how far biochemical data can be used as criteria in identifying cholinergic neurons. Known cholinergic cells of the periphery are found to contain both AChE and ChAc (choline acetylase, the enzyme that synthesizes ACh) By combined histochemical and biochemical analysis it can be shown that the AChE is present both in the perikaryal cytoplasm and in the axoplasm of cholinergic neurons and, in addition, is concentrated at their axon terminals, although at this site a proportion of enzyme is postsynaptic and apparently the product of the cholinoceptive cell which they innervate Where this characteristic disposition of AChE is observed it is highly probable that the cells in question are cholinergic However, the presence of enzyme in the cell body does not necessarily mean this since the cytoplasm of certain non-cholinergic neurons, including some sympathetic and spinal ganglion cells, also contain AChE in fairly high concentration Therefore, in order to find out if a cell is cholinergic, it is of greater importance to establish whether ChAc which has not been found in any proved non-cholinergic neurons is also present in it Unfortunately, there is no suitable micro- or histo-chemical technique by which to determine the cellular location of ChAc, so that in samples of the central nervous system it is usually not possible to identify the neurons from which it is derived and the information obtained from its measurement is quantitative only. In the central nervous system, expressed as the amount of ACh which can be synthesized per gm tissue per hr., its concentration may vary in some species of mammal from 0 to 5 μgm in tissues such as the optic nerve and parts of the cerebellar cortex to amounts equivalent to an activity of 3 mgm in the caudate nucleus; while in birds an even wider range of activity is found

These variations of ChAc have been interpreted to mean that the proportion of cholinergic to other neurons varies in different parts of the central nervous system, and that its concentration is larger or smaller depending on the numbers of such neurons To some extent it may also depend on which parts of them, the cell body, axon or axon terminals, are sampled since it appears that there is more enzyme at the axon terminals than elsewhere in the cell

In line with this interpretation all central structures containing ChAc have AChE associated with it, and in the case of some tissues containing a high concentration of ChAc it has been possible to show that the distribution of AChE in some of the constituent neurons conforms to what would be expected if they were cholinergic. In much of the brain and spinal cord it is not possible, however, to apply this test because of the difficulty of tracing neurons through to endings that are often remote from the cells of origin A new approach which helps to overcome this difficulty by determining the effect of chronic section on AChE in some central pathways has recently been described[4]; but at present, conclusions about the identity and course of cholinergic neurons in the central nervous system are largely a matter of inference

The ultimate test of whether a nerve is cholinergic is the demonstration that it releases ACh to transmit impulses to the cell or cells with which it synapses There is now evidence to show that ACh is released in the central nervous system, and in the case of the cerebral cortex it has been demonstrated that the rate at which this occurs is correlated with the level of cerebral activity as measured by the electroencephalograph and can be increased by electrical excitation applied locally, or at a distance to nerve pathways which have connexions with the cortex[5] In addition, some cholinoceptive neurons have recently been identified in certain cortical areas[6]. The biochemical evidence for the existence of central cholinergic neurons has therefore received substantial support from physiological experiment and there seems little reason to doubt that they form an important part of the central nervous system

There is, however, one other cause for uncertainty in interpreting the biochemical data This is the possibility, which has never been completely excluded, that some neuroglia may participate in ACh metabolism. As the presence of ChAc in some non-nervous tissues shows[7], ACh probably has some biological function other than that of neuro-transmitter and this could be true of the central nervous system as well as of other organs There is no question that all neuroglial cells can be concerned in ACh synthesis since there are many parts of the central nervous system which are nearly devoid of ChAc yet contain large amounts of glial tissue. Moreover, we find that certain fractions, obtained by low-speed centrifugation from homogenized brain tissue in which glial tissue is concentrated, have an extremely low specific activity of the enzyme So far as can be judged, therefore, this tissue does not participate to a significant extent in the production of ACh in the central nervous system Nevertheless, as will be appreciated, there are several kinds of neuroglia, and we cannot as yet be certain that the conclusion applies with equal force to all such tissue; and so, until more evidence is available on this point, some measure of uncertainty must remain in deciding whether the regional distribution of ChAc is related solely to the distribution of cholinergic neurons

Although there may be uncertainty in the positive identification of cholinergic neurons on biochemical data alone, there can be little or no doubt that if, as in the optic nerve and dorsal roots of most species, there is no measurable ACh or ChAc, such nerves cannot be cholinergic. It was on the basis of this kind of information that I concluded earlier that, at some central synapses, some transmitter other than ACh must be employed[2]; and, contrary to the suggestion made by Cavanagh and Holland, this conclusion applies to the hen as well as to mammals, because in this species the optic nerve has virtually no ChAc, synthesizing less than 0 1 per cent of the amount synthesized by pure cholinergic nerves. Moreover, in one experiment on a chicken in which I attempted the dissection of its spinal roots I found that the pooled dorsal roots synthesized only 4 per cent of the amount of ACh synthesized by the pooled ventral roots This small amount of activity could be accounted for by contamination of dorsal with ventral root tissue that had occurred in the course of the dissection, but even without this allowance the great difference in level of ChAc shows that a large proportion of the sensory fibres must be without enzyme and therefore non-cholinergic

Thus it seems reasonable to conclude that non-cholinergic as well as cholinergic neurons contribute to the nervous system of both birds and mammals.

Where there may be a difference between the two is in the relative numbers of cholinergic neurons, since the concentrations of both AChE and ChAc appear to be much higher in the chicken than in mammals In the cerebellum of the hen, for example, the ChAc activity is about eight times greater than the highest activity obtained from the cerebellum of any mammal Hence it is probable that relatively more cholinergic neurons contribute to the chicken cerebellum

It is of interest to consider this difference in relation to the comparative morphology of the cerebellum The virtual absence of ChAc from the outer layers of the cortex in many mammals indicates that few or none of its constituent neurons are cholinergic A similar conclusion can also be drawn from the AChE distribution, as Cavanagh and Holland stress[1] From our own evidence (Hebb, C O , and Mitchell, J F , unpublished work) based chiefly on ChAc measurements, it appears likely that the second-order sensory neuron from which the mossy fibres are derived are cholinergic and that these fibres supply most if not all of the enzyme in the white matter of the cerebellum. Thus, the concentration of ChAc would be expected to diminish as the cerebellum increases in size and complexity, largely owing to the addition of pathways which are not cholinergic connecting the cortex with other parts of the brain the relatively high concentration of ChAc in the hen cerebellum could then be attributed to its simpler structure and the relatively low numbers of non-cholinergic fibres in its white matter.

The alternative explanation, that the cortical neurons in the hen cerebellum are cholinergic, seems less likely It is suggested by the presence of AChE in some of the cortical neurons, the Purkinje cells in particular, but this argument loses force in view of the fact that in the pigeon cerebellum, which also has a high ChAc activity (about five times higher than in mammals), the cortical neurons appear to be devoid of AChE Another point to be considered is that the main cell groups of the cerebellar cortex seem to be homologous with one another in birds and mammals and in other vertebrates In view of this, it becomes less probable that they would alter in the specific chemical attributes that determine which transmitter substance they form, since from our knowledge of the peripheral and autonomic nervous systems the opposite conclusion may be drawn, namely, that anatomically homologous neurons are chemically homologous as well

Finally, I think it should be noted that the evidence provided by ChAc measurements does not support the idea that cholinergic neurons are in general of less importance in higher as compared with lower vertebrates Certainly the concentration of ChAc in the brain as a whole is greater in teleost fish and birds than in mammals, but in other vertebrates, the snake (*Natrix natrix*), the frog and the dogfish it is much lower. Within the mammalian group the enlargement of the cerebral cortex seems to have involved the addition of relatively more non-cholinergic than cholinergic neurons, but even in man it appears that cholinergic neurons form an important part of the cerebral cortex and in subcortical structures they have the same importance as in other members of the group

BLOOD AND SERUM GROUPS IN REINDEER COMPARED WITH THOSE IN CATTLE

By BO GAHNE and JAN RENDEL

Institute of Animal Breeding, Royal Agricultural College, Uppsala

DURING a search for possible markers for population genetic work on the reindeer species, blood samples were investigated from 64 reindeer at the State Reindeer Research Station, Ripats, Sweden. The samples were studied for the occurrence of cellular antigens, plasma protein and hæmoglobin types

Erythrocyte suspensions from 37 of the reindeer were tested against a battery of cattle blood-typing reagents, which detects 39 antigenic factors belonging to nine different genetic systems[1] Only one of the antisera (anti-*J*) gave specific hæmolytic reactions with any of the reindeer samples, while two reagents, *I′* and *Y′*, gave rise to some weak and probably unspecific cross-reactions The remaining samples were therefore only tested against anti-*J*

Of the 64 reindeer, 20 (31 per cent) were found to have cellular *J* Twenty-four calves, approximately 2 months old, were included in the investigation, and of these, 8 were found to have cellular *J* In the reindeer then, the *J* substance seems to be developed on the erythrocytes at least at two months of age

Anti-*J* occupies a peculiar position among the cattle blood-typing reagents It is obtained from normal sera and it reacts specifically with cells of types *A* and *AB* in man and with sheep *R* cells[2,3] The *J* substance, which behaves as a dominant genetic character, is primarily a soluble serum substance acquired by the erythrocytes after the birth of the animal[2,4] The concentration of the *J* substance in the serum and/or on the cells is, however, subject to considerable individual variation[4,5]

In order to study the presence of soluble *J* substance in reindeer serum, inhibition experiments were carried out according to standard techniques[4] Sera from nine individuals were examined Three animals had cellular *J*, while the remaining ones had no detectable *J* on their erythrocytes, neither had they anti-*J* in their sera One of our ordinary cattle *J* reagents was used as anti-serum, and the reindeer sera (in serial doubling dilutions) were used as inhibitors The inhibition tests were carried out in duplicates with *J*-positive reindeer and cattle erythrocytes as test cells The results (summarized in Table 1) show that the reindeer sera from animals having cellular *J* contain a soluble substance with the ability to inhibit the reaction between cattle

Table 1. ABILITY OF REINDEER SERA TO INHIBIT THE HÆMOLYTIC REACTION BETWEEN *J*-POSITIVE CELLS AND AN ANTI-*J* CATTLE SERUM DILUTED 1/16 (APPROX 4 UNITS OF HÆMOLYSIN)

Inhibitant	Highest dilution of the inhibitant causing inhibition	
	Cattle test cells	Reindeer test cell
Sera from 3 reindeer with cellular *J*	1/2–1/16	1/16–1/32
Sera from 6 reindeer lacking cellular *J*	No inhibition	No inhibition (3 cases) 1/4–1/8 (3 cases)

anti-*J* sera and cattle or reindeer cells of type *J* Three of the sera from individuals lacking *J* on their erythrocytes also inhibited the reaction between anti-*J* and reindeer *J* cells However, these three sera gave no definite inhibition when cattle cells were used as test erythrocytes The remaining three sera lacked inhibiting power entirely

Finally, a serum sample from each of the 64 reindeer was tested against erythrocytes from 30 reindeer and 10 cattle None of the 20 sera from animals with cellular *J* substance contained any antibodies However, 19 of the remaining sera contained antibodies against two or more of the red cell samples of type *J* One of these sera (No 5/55) was particularly strong In tests against all the reindeer samples and 90 cattle taken at random, the reactions of this serum exactly paralleled those of the cattle anti-*J* serum, which is in routine use in our laboratory The results from absorption experiments with the anti-*J* cattle serum and the reindeer serum No 5/55 are given in Table 2 As seen from the table, the *J*-positive cells from the reindeer species absorbed out the antibodies for the *J* cells in the cattle species and vice versa

Table 2 REACTIVITY OF ANTI-*J* SERA OF CATTLE AND REINDEER ORIGIN

Test cells	Cattle anti-*J* (No 451)			Reindeer anti-*J* (No 5/55)	
		Absorbed with			Absorbed with cattle *J* cells
	Un-absorbed	cattle *J* cells	reindeer *J* cells	Un-absorbed	
Reindeer					
J-pos.	+	–	–	+	–
J-neg	–	–	–	–	–
Cattle					
J-pos	+	–	–	+	–
J-neg	–	–	–	–	–

It can be concluded that the antigenic system in the reindeer species described here is remarkably similar to the *J* system of cattle and therefore the symbol *J* has been given to it Reindeer with cellular *J* also have soluble serum *J* However, as in cattle, soluble *J* substance seems to occur also in sera from some reindeer lacking cellular *J* Some reindeer sera contain normal antibodies with a specificity identical or very similar to cattle anti-*J* It is noteworthy that the serological similarity between the *J* systems in cattle and reindeer seems to be much greater than that between the cattle *J* and sheep *R* systems

No breeding data were studied, because the sires of the animals were unknown However, it seems justified to assume that the genetics of the *J* system in reindeer is similar to that in cattle[4,5]

The hæmoglobin and plasma proteins were investigated by starch-gel electrophoresis Using a continuous *tris*-buffer *p*H 8 9 (refs 6 and 7) only one kind of hæmoglobin was found among all the 64 reindeer It migrated a little faster than the cattle hæmoglobin *A*

The plasma proteins were analysed both with the continuous *tris*-buffer[6,7] and with a discontinuous buffer system[8] Six different types were observed regardless of the method used Fig 1 shows the six reindeer types compared with a bovine transferrin Tf^A/Tf^E type (ref 7). The variation seems to be in the β-globulins. By staining the starch gel with nitroso-R-salt reagent[9] the four varying zones, named *A-a*, *B-b*, *C-c* and *D-d*, were shown to bind iron and were therefore classified as transferrins Capital letters are used for the intensely stained zones and small letters for the less intensely stained zones. The six transferrin phenotypes can be designated ***aB***, ***bC***, ***cD*** ***aBC***, ***aBcD*** and ***bCD***

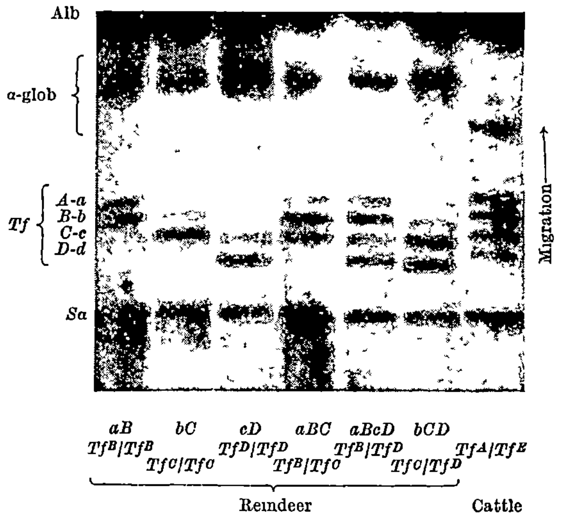

Fig 1 Photograph of the results of a starch-gel electrophoresis experiment with plasma from reindeer of the six transferrin types compared with the bovine Tf^A/Tf^E type Alb, albumin, α-glob, α-globulin, *Tf*, transferrin, *Sα*, slow α-globulin

A hypothesis is proposed that the transferrin types are determined by three alleles, called Tf^B, Tf^C and Tf^D Each allele gives rise to two transferrin fractions with a certain migration-rate in starch-gel electrophoresis The 64 reindeer are distributed in the following way with the phenotypes in parenthesis 6 Tf^B/Tf^B (*aB*), 18 Tf^C/Tf^C (*bC*), 4 Tf^D/Tf^D (*cD*), 15 Tf^B/Tf^C (*aBC*), 12 Tf^B/Tf^D (*aBcD*), and 9 Tf^C/Tf^D (*bCD*)

Among the reindeer tested there were 46 mother-offspring groups (several mothers had more than one offspring and sometimes daughters were mothers in other groups) The sires were unknown All offspring had a transferrin type compatible with that of their dam except in one case where a Tf^B/Tf^B daughter was assigned to a Tf^C/Tf^C mother This may be due to an error in the breeding records and therefore need not discount the three-allele hypothesis

A variation in the hæmoglobin-binding proteins was also observed but the results were difficult to interpret Some animals had a hæmoglobin-binding zone migrating slightly faster than the slow α-globulin while others had such a zone just behind the slow α-globulin However, in most animals no distinct hæmoglobin-binding zone appeared

We are much indebted to Dr M Nordkvist, of the State Veterinary Institute, Stockholm, who collected the samples of reindeer blood

ADENOSINE DIPHOSPHATE IN RED CELLS AS A FACTOR IN THE ADHESIVENESS OF HUMAN BLOOD PLATELETS

By A. GAARDER, Dr. J. JONSEN and Prof. S. LALAND
Department of Biochemistry

AND

Dr. A. HELLEM and Prof. P. A. OWREN
Institute for Thrombosis Research, Rikshospitalet, University of Oslo

The initial reaction of hæmostasis[1] and arterial thrombosis[2–4] is adhesion and aggregation of blood platelets to the wound surface and to the site of intimal damage. The elucidation of the mechanism of this reaction is of great importance not only for diagnosis and management of hæmorrhagic disorders, but also for the problem of thrombosis. Several factors are involved: (1) a property of the platelets which enables them to become adhesive when exposed to the physiological adhesiveness-producing mechanism (thrombasthenia represents by definition the congenital lack of this property), (2) a tissue substrate for the platelets to adhere to, probably collagen and elastic fibres[5,6], (3) a plasma factor, which is lacking in von Willebrand's disease[7] and (4) calcium. A fifth factor, possibly triggering the adhesion–aggregation reaction, was reported by Hellem as being an acidic, dialysable and heat-stable factor which was found in red blood cells[8]. This factor produced strong agglutination of platelets in citrated or oxalated plasma and converted the non-adhesive circulating platelets to adhesive platelets showing immediate adherence to foreign surfaces.

This article describes the identification of this factor as adenosine diphosphate. The effect of a number of other nucleotides on the adhesiveness of human platelets has also been examined.

The semi-quantitative test for the adhesiveness of human blood platelets described by Hellem[8,9] was used throughout this work. 0.05 ml. of saline containing the material to be tested was added to 0.5 ml. of platelet-rich plasma, and the reaction considered positive if clumping of the platelets occurred.

An extract obtained by treating human red blood cells with boiling water[8] was passed through a 'Dowex 1 × 8' column in the formate form. The column was eluted stepwise with increasing concentration of formic acid and ammonium formate–formic acid mixtures. A typical elution diagram of ultra-violet absorbing material recorded at 260 mμ is seen in Fig. 1. The eluted fractions (I–VI) were concentrated to dryness in vacuum in the frozen state, and then dissolved in a volume of saline equal to that of the original extract. Only fractions V and VI were positive in the platelet test. Occasionally the elution diagram would contain a large inactive peak at the site of fraction IV.

Fractions V and VI both yielded adenine on hydrolysis with *N* hydrochloric acid for 1 hr. at 100° C. as shown by paper chromatography in isopropanol/concentrated hydrochloric acid/water (68 : 17.6 : 14.4).

In electrophoresis at *p*H 5.7 in 0.2 *M* ammonium acetate at 900 V. for 2 hr., fraction V gave two ultra-violet absorbing zones, one of which had the same mobility and ultra-violet absorption spectrum in 0.1 *N* hydrochloric acid and in 0.1 *N* sodium hydroxide as adenosine diphosphate. By chromatography of fraction VI in isobutyric acid/concentrated ammonia/water *p*H 3.7 (66.1 : 1.0 : 32.9), three spots which corresponded to adenosine monophosphate, adenosine diphosphate and adenosine triphosphate were found.

The presence of adenosine diphosphate in fractions V and VI was definitely proved by a specific enzymic test[10] for adenosine diphosphate using reduced diphosphopyridine nucleotide–phosphoenol pyruvate phosphokinase, and lactic acid dehydrogenase. (Reagents for testing adenosine diphosphate were purchased from C. F. Boehringer and Soehne G.m.b.H., Mannheim.) The total change in the ultra-violet absorption at 340 mμ was used in calculating the amount of adenosine diphosphate present. In fractions V and VI, assuming all ultra-violet absorption at 260 mμ in 0.1 *N* hydrochloric acid to be adenosine diphosphate, 86 per cent and 50 per cent respectively were present according to the enzymic test for adenosine diphosphate.

Thus adenosine diphosphate was present in both the active fractions V and VI and proved to be the substance responsible for effecting the adhesiveness of the platelets. It is active in the test solution in a concentration of 0.02 μgm./ml. A similar activity was encountered with commercial adenosine diphosphate.

The presence of adenosine diphosphate as the only active substance in fractions V and VI was suggested by the following experiment: the smallest amount of the two fractions which produced a positive reaction in the test system contained, when calculated from the amount of adenosine diphosphate present in the fraction, approximately 0.02 μgm./ml., in agreement with the amount expected.

A number of commercial nucleotides have been tested for activity. The results are shown in Table 1.

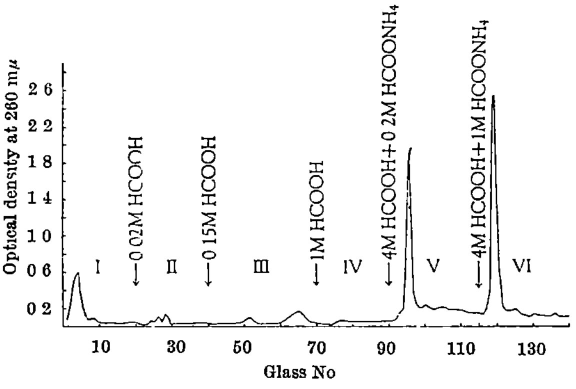

Fig. 1. Elution diagram from 'Dowex 1 × 8' (10 cm. × 1 cm.) in the formate form. 5-ml. fractions were collected. 27 mgm. of freeze-dried extract of red blood cells was dissolved in 5 ml. water and put on a column which was eluted stepwise as indicated in the diagram. The pooled fractions are indicated by I, II, III, IV, V and VI

Table 1 Effect of Unpurified Commercial Nucleotides on the Adhesiveness of Human Blood Platelets

The concentrations given for the active nucleotides represent the minimum concentration which will produce an effect

Nucleotide tested	Concentration of nucleotide in test solution (µgm /ml)	Clumping of blood platelets
Adenosine 5′-monophosphate sodium*	100	–
Adenosine 5′-diphosphate sodium†	0 02	+

§ Purchased from Mann

It is seen that deoxyadenosine diphosphate, guanosine diphosphate and cytidine diphosphate exhibited activity To decide whether the activity was genuine or due to traces of adenosine diphosphate, the substances were purified by paper chromatography in the isobutyric acid–ammonia–water solvent system which will separate adenosine diphosphate from any of the three diphosphates After purification, deoxyadenosing diphosphate was the only active material It was active in a concentration of approximately 7 µgm /ml , whereas the other two were inactive at a concentration of 100 µgm /ml

Adenosine triphosphate was active in a concentration of 2 µgm /ml , but was found by the enzymic test to contain approximately 1 per cent of adenosine diphosphate, which would account for the activity The commercial adenosine triphosphate was purified by paper electrophoresis in 0 1 *M* phosphate buffer *p*H 5 7, a procedure which separates adenosine diphosphate and adenosine triphosphate The latter substance after purification was inactive at a concentration of 84 µgm /ml , whereas the material corresponding to the mobility of adenosine diphosphate exhibited activity It follows that the presence of adenosine triphosphate does not prevent the activity of adenosine diphosphate Furthermore, the platelet system provides an extremely sensitive test for trace amounts of adenosine diphosphate.

The results suggest that the effect on the adhesiveness of the platelets is very specific since out of twenty-two nucleotides tested, only adenosine diphosphate and deoxyadenosine diphosphate were active, and furthermore that the 6-amino group in the purine ring and the pyrophosphate group are required for activity.

As a naturally occurring intracellular substance with the highly potent and specific effect described, it is logical to assume that the release of adenosine diphosphate by cellular damage may play an important physiological part as a trigger mechanism for the initial stages of hæmostasis and thrombosis Investigations of the mechanism of its interaction with platelets are in progress

DISSECTING ANEURISMS OF THE LARGE ARTERIES OF CHICK EMBRYOS DUE TO (SWEET PEA) LATHYRISM

By Z. ZÁHOŘ and M. MACHOVÁ
II Department of Pathology, Charles University, Prague 2

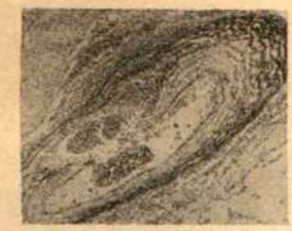
PONSETI and Baird in 1952[1] succeeded in producing dissecting aortic aneurisms in young rats fed on a diet containing 50 per cent *Lathyrus odoratus* Since that time, these vascular changes have been studied repeatedly by a number of workers β-aminopropionitrile has been found to have similar properties to the so-called *Lathyrus* factor By means of this compound, Lalich *et al* [2] were able to produce dissecting aneurisms in turkeys.

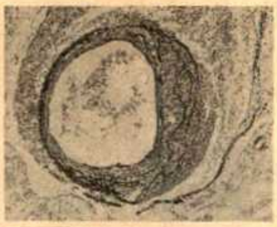
There is a high incidence of aortic aneurisms due to *Lathyrus* factor in developing rat fœtuses. We were able to demonstrate this fact clearly in some of our experiments[3] As a result of these experiments we attempted to produce vascular changes by means of fœtal chicken lathyrism.

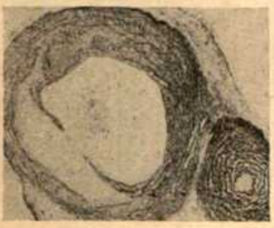
Lathyrus odoratus seeds were finely ground, and macerated in physiological saline solution (w/w, 1 2) at room temperature for 2 hr. The fluid obtained by pressing this thin, watery mash was rendered free from micro-organisms by using a bacteriological filter

Fertilized hen eggs (Leghorn white) were placed in special circular stands in a perpendicular position in an incubator, with the end of the egg containing the air space pointing upwards On the 7th day after placing the eggs in the incubator the top of each egg was opened so that a circular hole appeared having a diameter of 1–2 cm Each egg was covered by a glass vessel, allowing the access of air from beneath The embryos were examined twice a day

In our first experiment 50 eggs, treated as described, were divided into 5 equal groups Beginning on the 7th day, we applied different amounts of *Lathyrus odoratus* extract to each egg (using the hole at the top) belonging to groups 1–4 every day The eggs of group 5 were treated with saline solution only (0 4 ml. for one egg daily) The daily amounts of







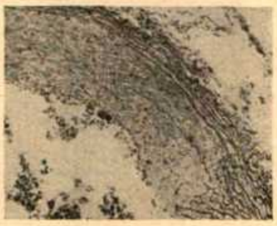


Fig. 1 (top, left). Ruptured dissecting aneurism of a branch of the pulmonary artery. (van Gieson's and Weigert's elastica stain, × *c.* 33)

Fig. 2 (top, right). Acute dissecting aneurism of ductus arteriosus. (Staining as in Fig. 1; × 50)

Fig. 3 (bottom, left). Acute, almost circular dissecting aneurism of the aorta. The ductus arteriosus is seen at the edge of the aorta. (Masson's trichrome and Weigert's elastica stain, × 25)

Fig. 4 (bottom, right). Scar in the aortic wall as a result of a healed dissecting aneurism. (Staining as in Fig. 3, × *c.* 83)

Lathyrus extract were as follows: Group 1, 0·05 ml./day; group 2, 0·1 ml./day; group 3, 0·2 ml./day; group 4, 0·4 ml./day. In the 3rd and 4th group, the fœtuses died very early, usually during the 10th or 11th day (that is, after 2–3 days of *Lathyrus* extract application). In group 2, 6 embryos died between the 11th and 13th day, the remainder of them dying between the 18th and 20th days. In the 1st experimental group, 7 embryos died between the 15th and 20th day, and the remaining 3 hatched out on the 21st day of incubation. In the control group, 2 chickens died on the 13th day, the remaining 8 hatched spontaneously on the 20th or 21st days.

Histological examination of the experimental animals that died during the course of the experiment very often disclosed extensive hæmorrhage, especially in the thoracic region. We were able to find acute massive dissecting aneurisms affecting one of the main branches of the pulmonary artery in 3 animals, belonging to the 1st and 2nd experimental groups (dying on the 19th and 20th days). In the control group, we failed to find any pathological changes.

In the second experiment 30 eggs, treated in the same way as above, were used. They were divided into 3 equal groups on the 12th day of their development. At this time, *Lathyrus* extract was injected in a single dose by a sterile needle into the albumen at the bottom of the eggs. The hole remaining after the puncture was closed by a paraffin plug. The amount of the *Lathyrus* extract injected was as follows: group 1, 0·5 ml.; group 2, 1 ml.: group 3, 2 ml.

In this experiment, the embryos died spontaneously even up to the end of their development, that is between the 18th and 21st day. Four chickens died in the first, 5 in the second, and 9 in the third experimental group. The remaining chickens hatched out on the 20th or 21st day. At birth, they required mechanical help, as they suffered from serious impairment of leg mobility. The surviving birds were killed on the following day by ether narcosis. The thoracic organs of all the chickens were serially sectioned *in toto* for microscopic examination.

In the animals of the first group minimal vascular lesions were found. In the second experimental group we were able to find extensive dissecting aneurisms in 4 chickens; both ducti arteriosi were affected in three chicks, the pulmonary artery once, and the aorta twice. In the third experimental group, dissecting aneurisms were disclosed in six chickens, the ductus arteriosi being affected most frequently.

Several workers have studied the effects of β-aminopropionitrile on connective tissue, using chicken embryos as the experimental animal[4-6]. Roy *et al.*[7] succeeded in producing aortic ruptures by means of 2-cyanopropylamine in young chickens after birth.

The method used in our second experiment seems especially suitable for the production of vascular lesions in chick embryos by *Lathyrus* factor.

We thank Dr. Z. Rychter and Dr. L. Lemez of the Institute of Normal Anatomy, Charles University, for technical advice.

MODIFICATION OF THE EFFECTS OF AN AMPHETAMINE–BARBITURATE MIXTURE BY THE PAST EXPERIENCE OF RATS

By Dr. HANNAH STEINBERG, Dr. RUTH RUSHTON and CHRISTINE TINSON

Pharmacological Laboratory, University College, London

AMPHETAMINE – BARBITURATE mixtures have been used in psychiatry for many years, for example in the treatment of anxiety states, and sometimes in preference to either drug on its own. Why such mixtures might be especially effective is not well understood: barbiturates in the fairly small doses used in psychiatry are usually intended to act as mild depressants or 'sedatives', while amphetamine is a cerebral stimulant and its effects on most kinds of response tend to be the opposite of those of barbiturates. Clinically, the effects of the two kinds of drug when given in combination seem to be regarded as 'mutually corrective'[1], that is, as somehow reinforcing each other's beneficial effects while mitigating each other's undesirable side actions. But relatively little systematic work on the effects of such mixtures on the behaviour of animals or man seems to have been done in the laboratory.

The purpose of the experiments described here was to study the effects of such a mixture, and of the two constituents separately, on the exploration of a new environment by laboratory rats. There is an extensive experimental literature on 'exploratory behaviour'. Many factors can affect it. There is evidence for the following generalizations[2-4]: Novel environments evoke in animals exploratory activities like walking about, rearing and sniffing which can be attributed to curiosity. Novel environments may, however, also have the opposite effect on behaviour; they may induce 'freezing' and if, for example, a noxious stimulus is introduced into a novel situation exploration is inhibited and may stop completely. These effects can be attributed to fear or anxiety. Both curiosity and fear are apt to diminish as familiarity with an environment increases, though they may do this at different rates. The actual amount of exploration in a given situation can thus be regarded as the net result of competition between two opposing tendencies; for example, radical novelty has been shown to evoke less exploratory behaviour than mild novelty, presumably because with radical novelty fear predominates. Miller[5] has shown in various experiments that the effects of fear induced in rats by electric shocks can be mitigated by barbiturates.

On this kind of analysis one might expect that drugs which can alleviate fear or anxiety would increase exploration of a radically novel environment; and they might have less effect in a more familiar environment where fear has already been largely overcome. In order to investigate this, two groups of rats were used: 'inexperienced' rats which had never been in the apparatus before, and 'experienced' rats which had been familiarized with the apparatus and had developed a relatively stable and high rate of exploring.

The apparatus was a symmetrical Y-shaped runway, 13 in. high. Each arm was 15 in. long and 5 in. wide. A trial consisted of placing a rat in the centre of the Y and leaving it in the apparatus for 3 min.; the number of times it entered the arms was the measure of exploration. Rearing and defæcation were also noted. There were no rewards. The rats were 48 adult Lister hooded females which had been reared under standard conditions since weaning and had been little handled. Throughout they lived in their home cages with food and water *ad lib.* All experiments took place between 2.30 and 5.30 p.m.

The procedure was as follows: when the rats were 117–127 days old they were allocated at random to the two experimental groups: (1) 'Experienced' rats, which were given regular trials in the runway, twice weekly, for 16 weeks. (2) 'Inexperienced' rats, which received an equivalent amount of handling but were not placed in the runway. At the end of the 16 weeks each group was divided at random into four sub-groups of 6 rats; three of each of the four sub-groups received a drug: (*a*) amylobarbitone sodium 15 mgm./kgm., (*b*) amphetamine sulphate 0·75 mgm./kgm., (*c*) these two doses combined in a mixture; the fourth sub-group were saline controls. For rats these doses are relatively small, but the proportion of barbiturate is rather higher than in the mixtures used clinically. The drugs were dissolved in saline so that the volume injected, subcutaneously, was 2 c.c./kgm. 35 min. after the injection each rat was given a single 3-min. trial in the runway.

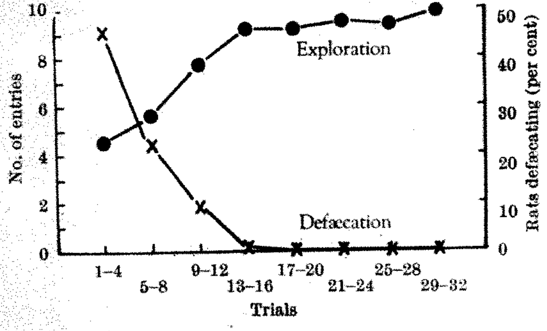

Fig. 1. Pre-drug trials of 'experienced' rats. The figure shows the mean number of entries into the arms of a Y-shaped runway made in 3 min. by 24 rats in 32 successive trials, and the percentage of rats which defæcated during these trials. The results have been grouped for four successive trials at a time, so that each point on the graph represents the mean results for four trials

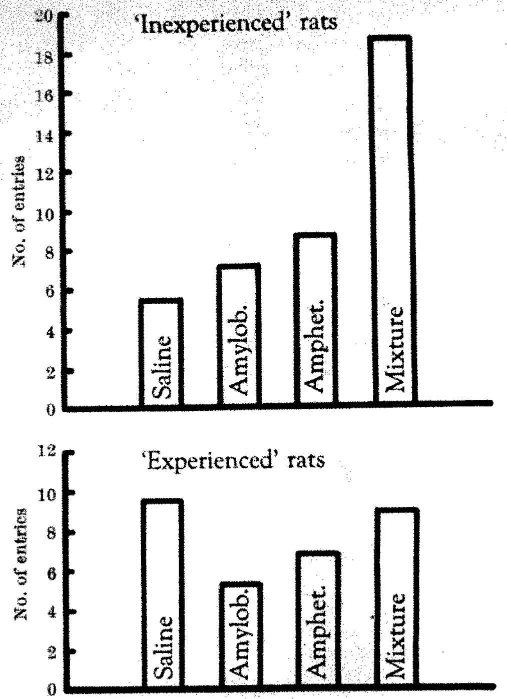

Fig. 2. Effects of drugs on exploration. The figure shows the mean number of entries into the arms of a Y-shaped runway made in 3 min. by four sub-groups of 'inexperienced' and of 'experienced' rats ($n = 6$). Three of each of the four sub-groups received a drug, respectively amylobarbitone sodium 15 mgm./kgm., amphetamine sulphate 0·75 mgm./kgm., and these two doses combined in a mixture; the fourth sub-group were saline controls

Pre-drug trials of 'experienced' rats. Fig. 1 summarizes the behaviour of the 'experienced' rats during the 32 pre-drug trials. At the first trial they explored relatively little (mean number of entries 5·79, *S.D.* 3·26), but in successive trials the amount of exploration gradually increased. From the 13th trial onwards the mean number of entries differed significantly from the first trial ($P < 0.02$) and soon remained fairly stable at about double the initial amount. Defæcation showed a corresponding decrease.

Effects of drugs. These are summarized in Fig. 2. The statistical significance of differences between sub-group means has been tested against the residual error, d.f. 40, discussed under (iii).

(i) 'Inexperienced' rats. The saline animals explored relatively little and spent much time sitting and 'freezing'. Their mean number of entries was 5·67, *S.D.* 2·25, which was similar to the mean number made by the experienced rats on their very first trial. Amylobarbitone and amphetamine barely increased exploration. The mixture, however, had a marked effect. the mean number of entries was 18·83, *S.D* 6·24, and this was more than three times the amount with saline ($t = 6\cdot11$, $P < 0\cdot001$). It was also noticed that the mixture induced unsteadiness of movement so that the rats had a rolling gait and sometimes toppled over, and some rats dragged themselves along on their bellies; in spite of this they continued to explore. Two of the amylobarbitone rats also showed some inco-ordination. It was further noticed that mixture rats were usually asleep in their home cages before being taken out for testing, and it was only in the new environment that they became active.

(ii) 'Experienced' rats. The experienced saline rats made a mean of 9·50 entries, *S.D.* 2·07, which was similar to their usual performance (cf., Fig. 1) and nearly twice the number made by the inexperienced saline rats. The drugs, however, had little effect on exploration. A few of the experienced rats showed motor inco-ordination with the mixture and with amylobarbitone, like rats in the corresponding inexperienced groups, but they explored no more than the experienced saline controls.

(iii) Interaction between 'experience' and 'drug' conditions. A two-way classification analysis of variance was carried out on the results for the four inexperienced and the four experienced sub-groups, and showed that the interaction between 'experience' and 'drug' conditions is highly significant ($F = 6\cdot64$, d.f. 3, 40, $P < 0\cdot001$). From Fig. 2 it is clear that the interaction arises in this way: among inexperienced rats the lowest mean was for saline controls while the highest mean was for the rats which had the mixture, the effect of 'experience' as compared with 'no experience' was to increase exploration under saline, but to inhibit the increase which the drug mixture induced in the inexperienced group.

These results suggest the following conclusions.

(1) Doses of amphetamine and amylobarbitone which separately barely affect exploratory behaviour can, when given in combination, have striking effects. These effects, moreover, seem to be in the same direction, that is the two drugs seem to act together to produce an increase in activity. Increased activity would not, of course, be surprising with amphetamine, but it is less usual with barbiturates. However, clinical reports have suggested that small doses of barbiturates, as of alcohol, can sometimes increase activity and excitement, and recently there have been some fresh and quantitative demonstrations of this kind of effect in laboratory animals[6-8].

(2) Whether an increase in exploratory activity occurs depends, however, not only on the drugs but also on the past experience of the animals: only rats which were unfamiliar with the new environment showed the increase. This is consistent with the assumption discussed at the outset (cf. ref. 9) that curiosity and fear may affect exploration in opposite ways and that the effect of the drug mixture should be to counteract fear. (i) Inexperienced saline rats, for whom the runway was a radically novel environment, explored less than experienced saline rats which had presumably already overcome their fear. That the experienced rats had indeed overcome their fear is also suggested by the gradual increase in exploration during the first 12 trials and by the corresponding decrease in defæcation. Defæcation has often been shown to be associated with fear and inversely related to activity (for example, ref. 10). Hence, by the time they were given drugs these rats were exploring at a rate consistent with a level of curiosity which had been stabilized by 32 previous trials, and so the drug mixture did not further increase it. (ii) But inexperienced rats given the mixture explored more than inexperienced saline rats, in other words, the drug mixture made them behave as though they were experienced and presumably unafraid. That these mixture animals explored even more than the experienced saline rats is not surprising since both curiosity and fear may be expected to be maximal on the very first occasion an animal meets a new environment, therefore, if fear is reduced, as by a drug, curiosity should more nearly show its maximal effect.

Even if further experiments do not confirm this interpretation in terms of curiosity and fear, the present results illustrate that (*a*) the effects of drugs may sometimes only become manifest if the experimental subjects have an appropriate past history, (*b*) 'inexperienced' animals can be more sensitive to drugs than highly trained animals. If the drug mixture had been tested only on experienced rats it would have been concluded that it had no effect on behaviour.

We wish to thank Profs. F. R. Winton, G. C. Drew and A. Summerfield and Dr. A. R. Jonckheer for discussing aspects of this work with us. The work was supported by research grant *MY*-3313 from the National Institute of Mental Health, U.S. Public Health Service.

BIOCHEMICAL ASPECTS OF PHAGOCYTOSIS

By Dr. G. Y. N. IYER, D. M. F. ISLAM and Prof. J. H. QUASTEL, F.R.S.
McGill-Montreal General Hospital Research Institute, 3619 University Street, Montreal, Canada

FOLLOWING a number of observations which indicated an increased rate of oxygen consumption by leucocytes during phagocytosis, Karnovsky and his colleagues[1-3] have shown that in the process of engulfment of particles by polymorphonuclear leucocytes, obtained from peritoneal exudates of guinea pigs, changes take place in the metabolism of the leucocytes. Increases in the rates of oxygen consumption and glucose utilization occur. The most significant change is the stimulation, during the phagocytic process, of the hexosemonophosphate shunt pathway of glucose oxidation. The ratio of glucose carbon 1 to glucose carbon 6 appearing in the respiratory carbon dioxide rises from a value of 8 in the resting (non-phagocytizing) leucocytes to a value of 22 during phagocytosis. Glycogen breakdown is increased[1,4] and there is some increase in lactate formation even though the rate of glycolysis in the leucocytes, both under aerobic and anaerobic conditions, is relatively high compared with that in many other mammalian cells. The energy for the phagocytic process seems to come from glycolysis[1]. Phagocytosis will take place under anaerobic conditions, or under aerobic conditions in the presence of a concentration of potassium cyanide that diminishes the respiration of leucocytes by 70 per cent (ref. 1). Acetate-1-^{14}C, uniformly labelled glucose-^{14}C, and phosphate-^{32}P are incorporated into the lipids of phagocytizing cells to a greater extent than into the lipids of resting cells[2,5], both under aerobic and anaerobic conditions. Incorporation of phosphate-^{32}P into phosphatidic acids is greatly increased as a result of phagocytosis[6].

The purpose of this communication is to report on certain other biochemical aspects of phagocytosis, particularly the stimulation of formate oxidation[7] and the possible bearing of this phenomenon on the mechanism by which oxygen consumption during phagocytosis is stimulated and its implications in the bactericidal processes accompanying phagocytosis.

The preparation of polymorphonuclear leucocytes was carried out by the method of Karnovsky *et al.*[1,8] with a few modifications. Guinea pigs weighing 400–500 gm. were injected intraperitoneally with 20 ml. 12 per cent sterile sodium caseinate solution. The largest numbers of leucocytes appear about 48 hr. after injection of the casein. In the following experiments, after 30 hr., the peritoneal exudates were collected in ice-cold calcium-free Krebs–Ringer medium containing 0·25 per cent sodium citrate, shaken and allowed to stand for 10 min. The cell suspension was slowly decanted from debris, centrifuged at 3,000 r.p.m. for 2 min., washed twice by resuspending in 8–12 volumes of ice-cold calcium-free Krebs–Ringer medium (*p*H 7·4). The packed cells were then diluted with the Ringer medium in the ratio 1 : 4. There was little or no contamination with red blood cells. For the preparation of a leucocyte homogenate, the following procedure was adopted. The leucocytes, after washing with calcium-free Krebs–Ringer medium, were diluted in the same medium in the ratio of 1 : 4. They were frozen, thawed and the thick suspension was homogenized for 3 min. in a Potter–Elvehjem glass homogenizer dipped in crushed ice, and the process of freezing, thawing and homogenization repeated. The homogenate was then centrifuged at 12,000 r.p.m. for 1 min. in the Sorvall centrifuge and the supernatant decanted off for use.

Much of the work described in this communication was carried out with leucocytes to which killed *E. coli* suspensions were added to induce phagocytosis. The *E. coli* cells were grown overnight on nutrient agar, collected, washed twice with 0·9 per cent sodium chloride solution, and then suspended in the same medium. They were killed by heating in a boiling water-bath for 30 min. and then centrifuged, washed with saline and suspended in calcium-free Krebs–Ringer phosphate medium.

The phagocytosis experiments were carried out in the conventional Warburg manometric apparatus at 37°. Krebs–Ringer medium (with 1·5 m*M* calcium chloride) was used as the suspending fluid. For respiration and glycolysis measurements, sodium phosphate buffer (0·02 *M*) and sodium bicarbonate (0·025 *M*) were used respectively. The initial *p*H was 7·4. The main compartment of the manometric vessel contained the leucocyte suspension (about 15 mgm. dry weight). 0·2 ml. (about 7 mgm. dry weight) heat-killed *E. coli* cells, radioactive substrates or other additions were usually tipped in from the side-arm. The centre well contained 0·2 ml. of 20 per cent potassium hydroxide with a roll of filter paper soaked in it; in experiments with potassium cyanide as inhibitor, the potassium hydroxide–cyanide mixture described by Umbreit *et al.*[9] was used. In aerobic experiments the gas phase was air and in anaerobic experiments purified nitrogen (or a mixture of 93 per cent nitrogen + 7 per cent carbon dioxide) was used. To free the nitrogen from traces of oxygen it was passed in succession through alkaline pyrogallol, Fieser's solution[10] and chromous chloride, and finally washed with lead acetate and barium hydroxide solutions. Such a rigorous purification was found necessary since the system oxidizing formate was found to be sensitive to the traces of oxygen still contained in commercial 'purified' nitrogen. After equilibration of the manometric vessels for 10 min. the contents of the side-arm were tipped into the main compartment of the vessel, which was incubated for 1 hr. at 37°.

Carbon-14 dioxide produced by the oxidation of ^{14}C-labelled substrates was absorbed in potassium hydroxide in the centre well of the Warburg vessel, trapped as bicarbonate and then liberated by addition of 0·3 ml. of 30 per cent trichloracetic acid which also served to terminate the reaction. The carbon dioxide was precipitated as barium carbonate in the presence of carrier, plated on aluminium planchets, and the radioactivity assayed using a thin-window gas-flow counter. The results were corrected for background and to infinite thinness of the barium carbonate layer. In experiments with ^{14}C-labelled formate, it was found that a small amount of radioactivity was always fixed by potassium hydroxide even in the absence of leucocytes; a correction had, therefore, to be applied in a routine manner for this.

The catalase we have used was a preparation from horse liver, kindly supplied by Dr. E. Margoliash of this Institute, and had an activity of 1,200 units/ml. (ref. 11).

Metabolism of Glucose-U-^{14}C by Guinea Pig Polymorphonuclear Leucocytes

Different particles were tested for their effects on the respiration of guinea pig polymorphonuclear leucocytes in the presence of glucose and on the rate of formation of carbon-14 dioxide when using uniformly labelled glucose. Typical results are shown in Table 1. Stimulated oxygen uptake has already been shown to take place with insoluble starch particles and polystyrene latex spherules about 1·17μ in diameter[1] and with a number of different bacteria; for example, *Mycobacterium tuberculosis*[12], *Bacillus subtilis*[12] and *Sarcina lutea*[13]. Results in Table 1 show that the highest stimulation of formation of carbon-14 dioxide among the particles tested was obtained with heat-killed *E. coli* cells. High rates of stimulation were also obtained with polystyrene latex spherules (obtained from the Dow Chemical

Company) and heat-killed *M tuberculosis* (B.C.G.) cells grown in a Dubos albumin medium for 7 days. It should be noted that carbon and sulphur particles stimulate leucocyte metabolism, but that freshly prepared barium sulphate and manganese dioxide particles have little or no effect under the given experimental conditions. Possibly the extra oxygen consumption found when sulphur particles are added to the leucocytes is due to some oxidation of the sulphur itself. Extracts of *E. coli* were also without effect. Addition of serum (final concentration 20 per cent) or peritoneal fluid (final concentration 10 per cent) to the suspending medium made no difference to the phagocytic stimulation due to killed *E. coli* cells.

Table 1. EFFECTS OF THE PRESENCE OF DIFFERENT PARTICLES ON THE OXYGEN UPTAKE AND CARBON-14 DIOXIDE FORMATION FROM GLUCOSE-U-^{14}C BY GUINEA PIG POLYMORPHONUCLEAR LEUCOCYTES

Each manometric vessel contained 4 m*M* glucose-U-^{14}C (10^5 c./min./vessel) and leucocytes (15 mgm. dry weight) *p*H 7.5, 3 ml., 1 hr.

Particles	Amount used (mgm.)	Oxygen uptake (µl./vessel)	Carbon-14 dioxide c./min./vessel
None	—	29	450
Carbon	20	58	1,670
Polystyrene (spherules)	15	124	3,430
Sulphur (powder)	60	565	1,220
$BaSO_4$ (pptd.)	95	24	660
MnO_2 (powder, fresh)	50	13	340
B.C.G. (heat-killed)	15	105	2,850
E. coli (heat-killed)	13	155	4,620

The largest accelerations of metabolism occur with fresh leucocytes. If these cells are incubated in a nitrogen atmosphere, in the absence of glucose, before the killed *E. coli* and labelled glucose are added, marked falls in the subsequent stimulated rates of oxygen consumption and carbon-14 dioxide production occur. The latter process is affected more than the former. The metabolic rates in the resting cells are apparently unaffected by this preliminary incubation procedure. The optimum *p*H for phagocytic stimulation was found to be between *p*H 7.5 and 8.5. It is noteworthy that the velocity of oxygen consumption by leucocytes, during phagocytosis of killed *E. coli*, remains nearly constant for about 40 min. at 37°, after which the velocity falls until, after 80 min., it has the same rate as that of the resting cells. Thus the stimulating process is of relatively short duration.

There is little doubt that the cationic concentrations in the media in which the leucocytes are suspended are of importance in the phagocytic stimulation of metabolism. Some typical results, given in Table 2, show that magnesium ions must play an important part in the stimulation, and that optimal effects are obtained only when magnesium, calcium and potassium ions are present with sodium chloride.

It has been pointed out[1] that phagocytic stimulation of metabolism by starch particles is proportional to the number of particles until a maximal value is reached. This is the case with killed *E. coli*. With 17 mgm. dry weight of leucocytes, the rates of oxygen consumption and carbon-14 dioxide are increased proportionately to the amount of killed *E. coli* added until approximately 6 mgm. dry weight bacteria have been added. Little further change occurs when larger quantities of bacteria are added. Similarly the increase in oxygen consumption and carbon-14 dioxide formation during phagocytosis is proportional to the numbers of leucocytes present, a maximum being reached with approximately 15 mgm. dry weight leucocytes (for the addition of 9 mgm. dry weight bacteria). With larger quantities of leucocytes (using this amount of bacteria to induce phagocytosis) there is no increase in the phagocytic stimulation of respiration and there is a fall in the phagocytic stimulation of carbon-14 dioxide formation from labelled glucose. This is possibly due to an increased demand on the glucose for glycolysis by the increased number of leucocytes. The results show that, within certain limits, phagocytic stimulation of metabolism is proportional both to the number of dead bacteria engulfed by the leucocytes and to the number of leucocytes used. It is therefore possible that the process of phagocytic stimulation may be employed for an assay method for phagocytosis.

Table 2. EFFECTS OF CATIONS ON METABOLISM OF LEUCOCYTES IN ABSENCE AND IN PRESENCE OF HEAT-KILLED *E. coli*

Glucose-U-^{14}C 4 m*M*, 120,000 c./min./vessel, leucocytes, 10 mgm. dry wt., *p*H 7.4, 1 hr.

Leucocytes washed and incubated in	Oxygen uptake (µl./vessel)		Carbon-14 dioxide (c./min. vessel)	
	Control	Phagocytosis	Control	Phagocytosis

Krebs–Ringer medium No magnesium or calcium ions	12	63	244	2,560
Sodium chloride (0.9 per cent)	9	28	286	1,800

Aerobic and Anaerobic Energy of Leucocytes

Polymorphonuclear leucocytes exhibit both Pasteur and Crabtree effects[1]. The presence of glucose depresses the respiration of leucocytes (Crabtree effect), but has no diminishing effect on the stimulated respiration during phagocytosis. Thus, in a typical result, the Q_{O_2} of resting leucocytes in the absence of glucose was 3.6, and in the presence of glucose 2.1, whereas with phagocytizing leucocytes the Q_{O_2} in the absence of glucose was 15.4 and in the presence of glucose 16.0. The Crabtree effect is evidently eliminated (or masked) by the phagocytic change of metabolism.

Examination of the relationship between aerobic and anaerobic glycolysis and the Crabtree effect in resting leucocytes shows that the rate of formation of adenosine triphosphate aerobically in the absence of added glucose is identical with that in the presence of added glucose, assuming a P/O ratio of 3, in leucocytes. This is seen in a representative result given in Table 3. This relationship is already known to hold with tumours[14]. Moreover, the adenosine triphosphate made available by anaerobic glycolysis is of the same order of magnitude as that produced

Table 3. RELATION BETWEEN AEROBIC GLYCOLYSIS $Q_{CO_2(O_2)}$ ANAEROBIC GLYCOLYSIS $Q_{CO_2(N_2)}$ AND INHIBITION OF RESPIRATION (CRABTREE EFFECT) OF RESTING POLYMORPHONUCLEAR LEUCOCYTES

aerobically (in the presence or absence of glucose) If adenosine triphosphate, made available aerobically or anaerobically, is an essential factor for the operation of the phagocytic process, it is evident that the process should take place as well anaerobically as aerobically, other conditions being the same There is considerable evidence[1] to support this conclusion

Evidently, since respiration is suppressed by cyanide or antimycin A (ref 1) without interference with phagocytosis, the adenosine triphosphate produced by respiration may be localized so that it is not available for the phagocytic process

Substrates affected by Phagocytosis

Representative results recorded in Table 4 show the effects of phagocytosis on the oxygen consumption and carbon-14 dioxide formation from a number of labelled substrates in the presence of guinea pig polymorphonuclear leucocytes and killed *E coli* In confirmation of earlier findings[1], it will be noted that the rate of formation of carbon-14 dioxide from glucose-1-^{14}C greatly exceeds that from glucose-6-^{14}C, justifying the conclusion that the hexosemonophosphate shunt is greatly stimulated by the phagocytic process Only quantitatively minor effects are seen with other substrates, with the exception of labelled formate, the rate of oxidation of which is greatly increased during phagocytosis

Aerobic and Anaerobic Oxidations by Resting and Phagocytizing Polymorphonuclear Leucocytes

During aerobic phagocytosis, the rate of oxidation of formate, as estimated by the increase of rate of formation of carbon-14 dioxide from formate-^{14}C is increased 3–6 fold Typical results recording the quantities of substrate (glucose or formate) oxidized by 1 mgm dry weight leucocytes per hr are shown in Table 5 Although the oxidation of formate is markedly stimulated, there is little or no increase (within the experimental error) in the rate of oxygen consumption during its oxidation The stimulation of oxidation of formate by phagocytosis is considerably less than that of oxidation of glucose

Under strictly anaerobic conditions, the rates of oxidations of glucose and formate are very greatly reduced and the phagocytic process, anaerobically, brings about only relatively small increases of these rates (Table 5) However, the addition of 0 3 per cent potassium ferricyanide, well known as an oxidant of reduced phosphopyridinenucleotide[15], to the leucocytes under strictly anaerobic conditions brings about an increased rate of formation of carbon-14 dioxide from glucose-U-^{14}C with the resting cells and a large stimulation of this rate with the phagocytizing cells The ratio of formation of carbon-14 dioxide from glucose-U-^{14}C by phagocytizing cells to that of resting cells is 9 2 in the presence of oxygen and 5 4 in presence of ferricyanide anaerobically The rate of carbon-14 dioxide formation, however, aerobically from glucose-U-^{14}C is at least twice that obtained anaerobically in presence of ferricyanide, with both resting cells and phagocytizing cells (Table 5) It is evident that, whereas ferricyanide can replace oxygen as an oxidant in the phagocytic processes, it is, under the given experimental conditions, much less effective What is also evident from the results given in Table 5 is that there is no stimulation, within experimental error, of formate oxidation by ferricyanide under anaerobic conditions

Experiments carried out with sodium pyruvate show that the addition of this substance to the leucocytes under strictly anaerobic conditions increases

Table 5 OXIDATION OF GLUCOSE AND OF SODIUM FORMATE BY GUINEA PIG POLYMORPHONUCLEAR LEUCOCYTES RESTING AND PHAGOCYTIZING, UNDER AEROBIC AND ANAEROBIC CONDITIONS

Gaseous phase	Substrates	Micromoles of substrate oxidized per mgm dry weight leucocytes per hour × 10^4	
		Resting	Phagocytizing
Air	Glucose-U-^{14}C	38	351
	Formate-^{14}C	24	96
Nitrogen	Glucose-U-^{14}C	5	12
	Glucose-U-^{14}C + potassium ferricyanide (0 3 per cent)	15	81
	Glucose-U-^{14}C + sodium pyruvate (5 m*M*)	32	37
	+ sodium pyruvate (10 m*M*)	27	35
	Formate-^{14}C	1	2
	Formate-^{14}C + potassium ferricyanide (0 3 per cent)	0 5	1 2
	Formate-^{14}C + sodium pyruvate (5 m*M*)	0 5	1 3

Each manometric vessel contained 15 mgm dry weight leucocytes, 0 6 ml Ringer medium (5 times normal strength), 0 5 ml 0 1 *M* phosphate buffer solution *p*H 7 4, 15 micromoles glucose Final vol = 3 ml Incubation = 1 hr at 37° Glucose-U-^{14}C, 10^6 c /min / vessel, 2 m*M* sodium formate, 1 5 × 10^5 c /min /vessel Phagocytosis induced by addition of heat-killed *E coli* suspension (7 mgm dry weight) the rate of formation of carbon-14 dioxide from glucose-U-^{14}C obtained with the resting cells almost to the aerobic level (Table 5). This fact lends support to the conclusion that pyruvate may be the normal oxidant for hexosemonophosphate oxidation via the shunt system[3,17]. On the other hand, the addition of pyruvate is less effective than ferricyanide in increasing the rate of formation of carbon-14 dioxide anaerobically with phagocytizing cells. Moreover, the amount of glucose-U-^{14}C converted to carbon-14 dioxide during phagocytosis aerobically is at least nine times that found on the addition of pyruvate anaerobically. It is therefore evident that whereas pyruvate can replace oxygen for glucose oxidation in resting leucocytes, it can only do so partially in phagocytizing cells. Mention should be made of the fact[21] that pyruvate can accelerate the aerobic rate of formation of carbon-14 dioxide from labelled glucose (or lactate) with ascites tumour cells, the effect being ascribed to exogenous pyruvate acting as an additional electron acceptor.

Effects of Metabolic Inhibitors and Stimulators on Glucose and Formate Metabolism during Phagocytosis

A large variety of substances has been tested for their effects on the stimulation of the rates of oxygen consumption and carbon-14 dioxide formation from glucose-U-^{14}C in presence of guinea pig polymorphonuclear leucocytes.

Antibiotics such as penicillin, streptomycin, chloromycetin, polymixin, bacitracin, gramicidin, sarcomycin were without effect at concentrations that were effective in suppressing bacterial growth.

Sodium amytal (5 m*M*), sodium malonate (10 m*M*) and sodium fluoracetate (10 m*M*) were without effect on the phagocytic stimulation of metabolism. On the other hand, those substances capable of suppressing glycolysis, such as phenylarsenoxide thioglycollate (30 μgm./ml.), glyceraldehyde (8 m*M*), phloretin (0.2 m*M*), as well as iodoacetate[1] and fluoride[1] bring about large inhibitions of stimulated phagocytic respiration and of carbon-14 dioxide formation from glucose-U-^{14}C. Thus the phenylarsenoxide thioglycollate brought about 87 per cent inhibition of carbon-14 dioxide formation from glucose-U-^{14}C, glyceraldehyde 72 per cent and phloretin 47 per cent. Phloretin also exercised a large inhibitory effect on the respiration of the resting cells. Again, sodium tartronate, known as a glycolytic inhibitor through its competitive suppression of lactic dehydrogenase[18], exercises a considerable inhibition of both glycolysis and phagocytic stimulation of leucocytes. At a concentration of 50 m*M* it inhibited glycolysis by 40 per cent and carbon-14 dioxide formation from glucose-U-^{14}C by 34 per cent in resting cells, and 68 per cent in phagocytizing cells. Sodium oxalate, another inhibitor of lactic dehydrogenase[19], behaved similarly to tartronate.

These results support the conclusion that, although the energy required for phagocytosis is obtained by glycolysis, the phagocytic stimulation of metabolism consists largely of an acceleration of the hexomonophosphate shunt pathway of oxidation and to a minor extent of an acceleration of lactic acid formation[1]. As the former process is mediated by triphosphopyridine nucleotide, it was desirable to test the effects, on the process, of substances known to stimulate oxidation of triphosphopyridine nucleotide, for example, menadione and pyruvate[16,17]. It was found that a variety of quinones, including menadione, increase markedly the rates of oxygen consumption and of carbon-14 dioxide formation from glucose-U-^{14}C of resting leucocytes with but little effect on the phagocytic stimulated rates of oxygen consumption and of carbon-14 dioxide formation. Representative results given in Table 6 show that naphthoquinone (0.3 m*M*) and menadione (0.3 m*M*) increase the rates of oxygen consumption and carbon-14 dioxide formation from glucose-U-^{14}C with resting cells several-fold, menadione being the more effective substance, while the phagocytic stimulation is only increased about 20 per cent. Vitamin K_1 and α-tocopherol quinone have little effect on the rates of oxygen consumption but increase the rates of carbon-14 dioxide formation from glucose-U-^{14}C with resting cells more than 100 per cent, and with phagocytizing cells 43 and 24 per cent respectively at the concentrations tested. It is therefore evident that quinones can stimulate the formation of carbon-14 dioxide from resting cells, sometimes to the phagocytic level, but they have much less effect on the formation of carbon-14 dioxide from phagocytizing cells. The accelerating effect of menadione on formation of carbon-14 dioxide is seen with glucose-1-^{14}C and not with glucose-6-^{14}C (Table 6), as would be

Table 6. PERCENTAGE EFFECTS OF QUINONES, ETC., ON METABOLISM OF POLYMORPHONUCLEAR LEUCOCYTES

See Table 4 for control values

expected if the acceleration due to menadione were confined to the hexosemonophosphate shunt

Phenazine and methylene blue are also accelerators of the rates of oxygen consumption and carbon-14 dioxide formation in the presence of labelled glucose, their effects on the metabolism of resting cells being greater than on that of phagocytizing cells (Table 6) Phenazine is much more active than methylene blue in this respect It is noteworthy that phenazine permits the direct oxidation of reduced diphosphopyridine nucleotide[20]

Sodium pyruvate has little or no effect on the rates of respiration of resting and phagocytizing cells, it increases (at 8 mM) the formation of carbon-14 dioxide from glucose-1-^{14}C by 74 per cent with resting cells, but has no effect on that obtained with phagocytizing cells Its effects are very clearly seen on leucocytes treated with iodoacetate, for it nearly abolishes the inhibition of the rate of formation of carbon-14 dioxide by iodoacetate in resting cells (Table 6) On the other hand, it has a relatively small effect in diminishing the inhibition by iodoacetate of formation of carbon-14 dioxide with phagocytizing cells.

While these results indicate that pyruvate will increase the rate of formation of carbon-14 dioxide from labelled glucose with resting cells by at least 74 per cent, both with normal cells and with cells treated with iodoacetate, and that it may, therefore, act as an oxidizer of reduced triphosphopyridine nucleotide, it is clearly very ineffective as compared with a quinone such as menadione or a carrier such as phenazine Moreover, the fact that it cannot increase the rate of oxygen consumption, or of carbon-14 dioxide formation, of resting cells to the phagocytic levels indicates that phagocytic stimulation cannot be wholly due to an increased rate of liberation of pyruvate in the leucocyte during the process of phagocytosis It should be noted that menadione (Table 7) increases the rate of formation of carbon-14 dioxide from formate-^{14}C with resting leucocytes almost to the phagocytic level

Sodium iodoacetate (0 1 mM)	26	259	10	25

Evidence for Hydrogen Peroxide Formation during Phagocytosis

Experiments, typical results of which are shown in Table 7, show that the formate-oxidizing mechanism is greatly inhibited by concentrations of sodium azide and potassium cyanide that have but little effect on the oxidation of glucose, either with resting or phagocytizing cells Iodoacetate has an inhibitory effect on formate oxidation approximately equal to that on glucose oxidation The facts indicate that formate oxidation in the leucocyte is dependent on that of glucose, that it requires molecular oxygen as an oxidant and that it is blocked by inhibitors that affect enzymes containing hæm As it is already known that leucocytes are rich in peroxidase[22], and as the optimum pH for phagocytic stimulation of formate oxidation is 6 0, which is the optimum for peroxidase, it is reasonable to conclude that oxidation of formate is accomplished by hydrogen peroxide formed during the oxidation of glucose by the hexosemonophosphate shunt It is already known[23] that in the presence of peroxidase or catalase, hydrogen peroxide oxidizes formate and that azide and cyanide will inhibit the activity of verdoperoxidase

Evidence that hydrogen peroxide is actually formed during phagocytosis comes from experiments the results of which are shown in Table 8 In the first place it is evident that the addition of catalase more than doubles the rate of oxidation of formate in the presence of resting or phagocytizing leucocytes, whereas the addition of heated catalase has no effect Such an accelerating effect must be attributed to the action of catalase on hydrogen peroxide leaking from the leucocyte, as we have found no evidence that the catalase content of the leucocyte is increased on exposure to catalase Secondly, the addition of sodium nitrite (2 mM) which will act as competitor to formate[23] brings about an inhibition of oxidation of formate by resting or phagocytizing leucocytes. Moreover, the system oxidizing formate is to be found in the leucocyte homogenate, which is capable of extensive oxidation of formate in the presence of a system producing hydrogen peroxide such as is afforded by a mixture of glucose oxidase (notatin) and glucose (Table 8)

Table 8 FACTORS AFFECTING AEROBIC OXIDATION OF FORMATE BY LEUCOCYTES AND LEUCOCYTE HOMOGENATES

Formate-^{14}C (2 mM) present throughout Glucose = 5 mM Notatin = 0 01 per cent

	10^4 × μmoles formate oxidized/hr /mgm leucocytes
Resting leucocytes	
Leucocytes only (pH = 6 0)	36
Notatin + glucose	0
Leucocytes + notatin + glucose	715
Leucocytes + notatin + glucose + sodium azide (1 mM)	1
Leucocytes only (pH = 7 4)	18
+ sodium azide (1 mM)	0 8
+ potassium cyanide (1 mM)	6
+ catalase (1/750)	40
+ heated catalase (1/750)	18
+ sodium nitrite (2 mM)	3
Phagocytizing leucocytes	
Leucocytes only (pH = 7 4)	86
+ catalase (1/750)	198
+ heated catalase (1/750)	87
+ sodium azide (1 mM)	2
+ sodium nitrite (2 mM)	12
+ potassium cyanide (1 mM)	9
Leucocyte homogenate	
Homogenate only (pH = 6 0)	65
+ glucose + notatin	529
+ glucose + notatin + catalase (1/15,000)	708
Glucose + notatin + catalase (1/15,000)	105
Homogenate + glucose + notatin + sodium azide (1 mM)	5
Homogenate + sodium azide (1 mM)	3
Homogenate + sodium nitrite (2 mM)	6

The evidence indicates that the systems oxidizing glucose (by the hexose monophosphate shunt pathway) and formate are present in the non-particulate cytoplasmic fraction of the leucocytes, a fact in agreement with observations concerning the localization of glucose-6-phosphate and 6-phosphogluconic acid dehydrogenases in many other tissues[25]

Oxidation of Sodium Sulphite by Resting and Phagocytizing Leucocytes

A substance that greatly increases the rate of oxygen uptake of leucocytes undergoing phagocytosis is sodium sulphite In a typical experiment this substance (at 30 mM) increased the oxygen consumption per hour of 12 mgm (dry weight) resting leucocytes from 30 µl to 60 µl, and of phagocytizing leucocytes from 120 µl to 700 µl. At the same time it diminished carbon-14 dioxide formation from glucose-U-^{14}C, with phagocytizing cells, by 90 per cent. Oxidation of formate-^{14}C to carbon-14 dioxide was also suppressed by sodium sulphite, an inhibition of 47 per cent occurring with 10 m*M* sodium sulphite. The reasons for these effects are now being investigated.

Participation of Flavin in the Formation of Hydrogen Peroxide in Leucocyte Homogenates

Results, which will be described in detail elsewhere (Iyer, G. Y. N., and Quastel, J. H., to be published), show that homogenates of guinea pig polymorphonuclear leucocytes are capable of oxidizing in the presence of air the reduced forms of di- and triphosphopyridine nucleotides to hydrogen peroxide, as indicated by oxidation of formate-^{14}C to carbon-14 dioxide. Reduced triphosphopyridine nucleotide is more effective than the reduced diphosphopyridine nucleotide in this respect. It seems likely that this mechanism underlies the formation of hydrogen peroxide during phagocytosis. The addition of flavin mononucleotide (0.01 m*M*) accelerates the rates of oxygen consumption of the leucocyte homogenate in presence of reduced di- or tri-phosphopyridine nucleotide. Moreover (Table 7), the addition of flavin mononucleotide increases the rate of formation of carbon-14 dioxide from formate-^{14}C in the presence of the resting leucocytes. These facts support the conclusion that a system catalysed by flavin is involved in the oxidation of the reduced di- and triphosphopyridine nucleotides by leucocytes to form hydrogen peroxide.

The liberation of a reduced di- or tri-phosphopyridine nucleotide oxidase, capable of producing with these dinucleotides, hydrogen peroxide, during the process of phagocytosis, or that of a quinone linking reduced di- or tri-phosphopyridine nucleotide with molecular oxygen, would account for the observed phenomena. Possibly the release of enzymes from the granules of polymorphonuclear leucocytes, shown by Cohn and Hirsch[26] to occur during phagocytosis, is involved in these phenomena[3,6].

Formation of Hydrogen Peroxide in Leucocytes during Phagocytosis

Calculations indicate that if the increased oxygen consumed by the guinea pig leucocytes on phagocytosis is wholly converted to hydrogen peroxide, the amount of the latter formed will amount to 0.39 micromole per mgm. dry weight leucocytes at *p*H 7.4. This corresponds to a concentration of approximately 100 m*M* in the leucocyte, assuming no leakage. If, however, the increase in oxidation of formate by the leucocytes on phagocytosis may be considered as the measure of hydrogen peroxide formation, this will amount to 1·3 m*M* at *p*H 7.4. At a lower *p*H, for example, 6.0, the corresponding values are 26 m*M* hydrogen peroxide (calculated from the increased amount of oxygen uptake) and 6.2 m*M* (calculated from the increased oxidation of formate. It is evident that the amount of hydrogen peroxide formed will vary according to the amount of phagocytosis and the intracellular *p*H and that it may vary from 1 m*M* to 100 m*M*. The latter concentration of hydrogen peroxide is known to be highly toxic to *E. coli*[27], but whether such an amount is actually formed is still uncertain. Nevertheless, in the consideration of the various factors that may operate in bringing about bactericidal action during phagocytosis, the possibility that hydrogen peroxide is formed during this process must be taken into account. It is unlikely that hydrogen peroxide is wholly responsible for the non-specific bactericidal effects of phagocytosis[28,29], but it will surely be one of the responsible agents.

Summary

Phagocytosis by guinea pig polymorphonuclear leucocytes is accompanied by an increased rate of oxidation of formate. Formate oxidation is linked with the oxidation of glucose and is sensitive to cyanide and to azide. Whereas glucose oxidation, anaerobically, may be stimulated by the presence of ferricyanide or pyruvate, formate oxidation under these conditions does not occur. The evidence indicates that whereas added pyruvate can replace oxygen as an oxidant with non-phagocytizing leucocytes, it is relatively ineffective with phagocytizing cells. The results also indicate that oxidation of reduced phosphopyridine nucleotides in leucocytes is accompanied by formation of hydrogen peroxide which is responsible for oxidation of formate. It is possible that the stimulation of glucose oxidation that occurs during phagocytosis is due to liberation of oxidase systems reacting with molecular oxygen to form hydrogen peroxide. The implications of the latter process on the non-specific bactericidal effects occurring in phagocytosis are discussed.

ASTROPHYSICS

Atmospheric Scale Height as a Modifying Influence on Linear Trend of F-Region Electron Density with Sunspot Number

IN the prediction of maximum usable frequencies a linear increase in *foF*2 with sunspot number is generally assumed for practical purposes[1] However, an analysis of maximum usable frequencies, estimated for a sunspot cycle interval from Christchurch ionospheric vertical sounding data obtained during 1947–58, indicated that the trend of twelve-month running average values of *foF*2 monthly medians with twelve-month running average sunspot number showed significant departures from linearity especially in the daylight hours and above running average sunspot number 170 at the 1957–58 sunspot maximum Chun-Ming Huang[2] has observed a similar marked departure from linear trend at the 1957–58 maximum in an analysis of vertical sounding stations in the Western Pacific area, the time of onset relative to sunspot number varying with time of day and station latitude

A critical examination of Christchurch trends in noon values of maximum *F*2 ion density ($N_{\max}$) and true height ($h_{\max}$) was made to discover possible modifying influences contributing to the observed *foF*2 departures The plot of twelve-month running average values of $N_{\max}$ vs running average sunspot number (Fig 1) showed that departure from a linear trend is clearly defined for median, calm and disturbed conditions above running average sunspot number 170

The noon maximum ion density at a fixed pressure-level can be assumed to be an approximation to the equilibrium value·

$$N = \frac{q}{\beta}$$

where q is the rate of ion production and β is the rate of loss by an attachment-like process

On this assumption, if height changes, and changes in β throughout a cycle are neglected, an increase in q with sunspot number due to an increasing incident ionizing radiation could explain the main linear increase in $N_{\max}$ of the order of 4 1 for calm conditions. Height changes, however, indicative of scale height variations appear to be significant in modifying the electron density increase due to increasing q

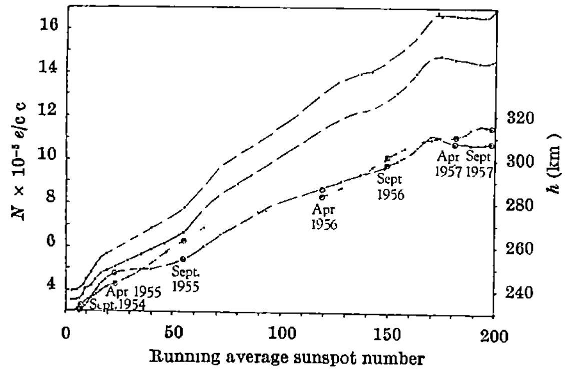

Fig 1 Twelve-month running averages of $N_{\max}$ vs running average sunspot number 1954–58 showing non-linearity above running average sunspot number 170 and annual residual variation. Full lines, ion densities, dotted line, median heights Upper, middle and lower curves are for calm, medium and disturbed conditions respectively

True height values of $h_{\max}$ for representative calm days 1954–58 were available from *N′h* profiles computed by Cummack using the method of King[3] Where the coverage was not complete for this period a relatively quick computation of $h_{\max}$ using the median trace method[4] combined with a slider technique was used The latter values were in reasonable agreement with the more rigorous calm-day computations and satisfactory for the purpose required

Twelve-month running average noon values of $h_{\max}$ for the 1954–58 interval were plotted on the ion density graph and the height trend coincided with the disturbed ion density trend (Fig 1). This latter exhibited similar departure from linearity to the median and calm ion density trends and was therefore taken as the ion density standard of reference for purposes of comparison

Above running average sunspot number 170 the height trend as shown in Fig 1 was maintained for a time after the linear increase in ion density had degenerated

Assuming that (1), height increases are indicative of increased scale height (H), and (2), that $qH \propto I$, where I is the incident ionizing radiation, it is postulated that critical increases in scale height near the 1957–58 sunspot maximum have been large enough to modify the increase in q resulting in a relative decrease in $N_{\max}$ at this stage of the cycle. As the ion density departures were similar under both calm and disturbed conditions, the effect of increased incidence of storms near sunspot maximum is not considered to be a major contributing factor to this phenomenon.

Fig 1 also shows that a residual annual variation remains during the years 1954–56 after the main seasonal variation has been eliminated by the smoothing process Relative ion density maxima and height minima centre on April while corresponding ion density minima and height maxima centre on September It can be considered that twelve-month running averages for April and September include the same equinoctial and winter months April–October. In addition, the April average includes the effect of the preceding summer months and the September average the effect of the following summer months As a result of the smoothing process, therefore, any marked departures from linearity occurring in the trend due to the effect of modifying influences in succeeding summer seasons could be at a maximum at the April and September points on the graph The observed residual annual departures then can imply that summers nearer sunspot maximum are characterized by a relative decrease in $N_{\max}$ associated with increase in scale height This deduction was supported in an examination of the declining phase of the cycle where height and ion density departures for April and September were found to be reversed, again implying that summers nearer sunspot maximum show a greater relative decrease in $N_{\max}$ due to relatively increased scale heights than those nearer sunspot minimum.

As the increase in summer heights from sunspot minimum to maximum (240–350 km.) is much greater than the increase at other seasons (230–280 km. in winter) a modifying influence due to increasing scale heights would be expected to be greater for summer as suggested However, a more refined discussion, including the effect of changes in β, is needed to account for the detailed seasonal behaviour pattern of $N_{\max}$ observed at Christchurch throughout the sunspot cycle investigated

A full account of the analysis of estimated values of maximum usable frequencies throughout a sunspot cycle and associated electron density trends at Christchurch will be published in the *New Zealand Journal of Geology and Geophysics* The survey includes detailed observations of seasonal trends in $N_{\max}$ throughout the cycle and examines sunspot cycle changes in diurnal trends of ionospheric storm departures

PHYSICS

Triple Resonance Phenomenon in Plasmas

INTERACTIONS between electromagnetic waves and weakly ionized plasmas in the presence of a steady magnetic field have been widely investigated[1] The Appleton–Hartree formula for the equivalent complex dielectric constant of the plasma is partially reproduced in graphical form in Figs. 1 and 2 These graphs are restricted to the case that the propagation vector and E-polarization of the electromagnetic wave are both perpendicular to the direction of a uniform steady magnetic field With these restrictions, the relative dielectric constant can be written

$$\varepsilon' = \frac{\varepsilon}{\varepsilon_0} = \varepsilon_r - \frac{j}{\omega\varepsilon_0} = \frac{\varepsilon_{11}{}^2 + \varepsilon_{12}{}^2}{\varepsilon_{11}} \tag{1}$$

in which

$$\varepsilon_{11} = 1 + \frac{\omega_p{}^2}{j\omega}\,\frac{\nu + j\omega}{(\nu + j\omega)^2 + \omega_b{}^2} \tag{2}$$

$$\varepsilon_{12} = -\frac{\omega_p{}^2}{j\omega}\,\frac{\omega_b}{(\nu + j\omega)^2 + \omega_b{}^2} \tag{3}$$

where ω is the radian frequency of the wave, ν is the collision frequency. $\omega_b = eB/m$ is the cyclotron frequency, $\omega_p = \sqrt{\frac{ne^2}{m\varepsilon_0}}$ is the plasma frequency, e and m are the charge and mass of an electron B is the strength of the steady magnetic field, n is the volume density of free electrons in the plasma, and ε_0 is the permittivity of free space A dependence on time of $e^{j\omega t}$ has been assumed

When $\nu = 0$, the insertion of (2) and (3) in (1) leads simply to the result that the relative dielectric constant alternates between regions of positive and negative values as the electron density is increased Thus the electromagnetic wave is propagated if the free electron density is less than the value corresponding to $\omega_p{}^2 = \omega(\omega - \omega_b)$ It is cut off in the range $\omega(\omega - \omega_b) < \omega_p{}^2 < (\omega + \omega_b)(\omega - \omega_b)$ and is then propagated again in the range $(\omega + \omega_b)(\omega - \omega_b) < \omega_p{}^2 < \omega(\omega - \omega_b)$ For all electron densities greater than the value corresponding to $\omega_p{}^2 = \omega(\omega + \omega_b)$ the electromagnetic wave is not propagated It is apparent that increasing ω_b serves to separate these boundaries farther from each other In the laboratory, it is possible to achieve a sufficiently large ω_b/ω to make this triple resonance effect detectable

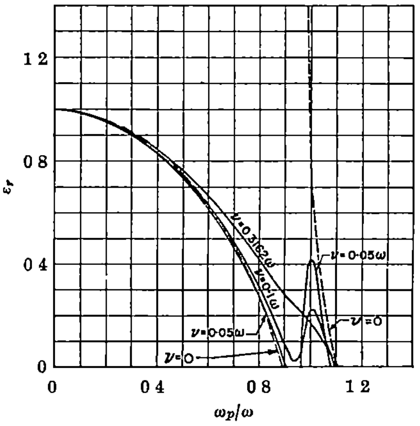

Fig 1 Relative dielectric constant versus normalized plasma frequency ($\omega_b = 0\ 2\ \omega$)

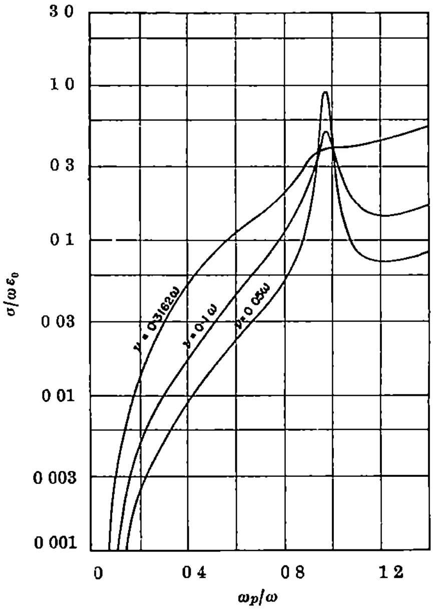

Fig 2 Normalized conductivity versus normalized plasma frequency ($\omega_b = 0\ 2\ \omega$)

The inclusion of collision losses serves to broaden these resonances, as in any problem in which Q is lowered However, it is interesting to note that a sufficiently high value of ν will erase the triple resonance effect entirely, as shown in the ε_r curves of Fig. 1 This proved to be a formidable stumbling block in the experimental work which was undertaken to demonstrate this phenomenon

An apparatus similar to one used earlier by Anderson[2] was employed. A 19-mm. outside diameter 'Pyrex' tube with a 1.5 mm. wall was placed inside a square brass wave-guide. The glass tube was 42 in. long with the last 3 in. on each end tapered to a point. The inside dimensions of the wave-guide were 0.805 in. by 0.805 in. with 0.035-in. walls. 5.5-in. wave-guide transitions coupled each end of the square guide to standard X-band wave-guide for connexion to the remainder of the microwave system. A klystron source was operated at 8,600 mc.p.s. and unmodulated.

The tube was attached through a hole in the wave-guide wall, with a 10-mm. nipple, to a spherical bulb of 3 in. diameter. The latter contained the ignitor electrode, auxiliary anode, and mercury pool cathode from a *GL*-5779 'Ignitron'. A second hole in the wave-guide wall, at the other end of the plasma column, accommodated a 5-mm. nipple which housed the main anode, a 0.1-in. diameter tungsten rod. The rod did not project into the plasma column, its end was even with the inside wall of the main tube. Continuous pumping was used to maintain the vacuum between 10^{-6} and 10^{-7} mm. of mercury.

A transverse d.c. magnetic field was impressed on the plasma by inserting the square wave-guide between the 1-in. wide by 57-in. long poles of an electromagnet. The magnet core was constructed of 1020 cold-rolled steel. The 17-gauge heavy 'Formvar' winding was continuous around the 57-in. dimension of the magnet, giving a uniform magnetic field along the entire length of the plasma column. A 0–150 V. d.c. generator supplied a maximum of 4 amp. to the winding to give a maximum field of 1,200 gauss.

The ignitor electrode was pulsed at 60 c.p.s. from a 600 V. supply and the main anode was energized from a composite source—5 kV. to provide a d.c. current plus a variable 60 c.p.s. supply to superimpose a sinusoidal variation on the d.c. current. In this manner, the plasma properties were made to vary at a 60-c.p.s. rate with controllable excursions. The results of this experiment were recorded by photographing the traces of a dual beam oscilloscope for various values of d.c. magnetic field. A representative set of traces is reproduced in Fig. 3. In each display the upper trace is the a.c. component of tube current and the lower trace is the detected microwave signal which has traversed the plasma column. All the oscillograms shown in Fig. 3 were taken with 420 m.amp. d.c. and constant amplitude a.c. through the discharge tube. The negative peak of the upper trace corresponds to minimum electron density in the plasma, a value small enough to cause essentially full transmission of the microwave signal in the absence of a d.c. magnetic field.

The lower traces have many features in common. The 8,600-mc.p.s. wave is cut off until such time as the current through the plasma tube (and thus the electron density) lowers to the point where propagation begins; this is a resonant point. The propagation then rises to a peak, giving a second resonant point. The propagation again decreases, the minimum point giving a third resonance. The propagation then rises to a maximum value of transmission. As the tube current increases in value this sequence is repeated in reverse order.

It is evident that as the d.c. magnetic field is increased, and both the d.c. and a.c. current-levels are kept constant, the transmission-level decreases. This is attributable to the increases in electron density and collision frequency which accompanied the increases in the d.c. magnetic field. It is interesting that Beckman[3] has predicted just such an effect.

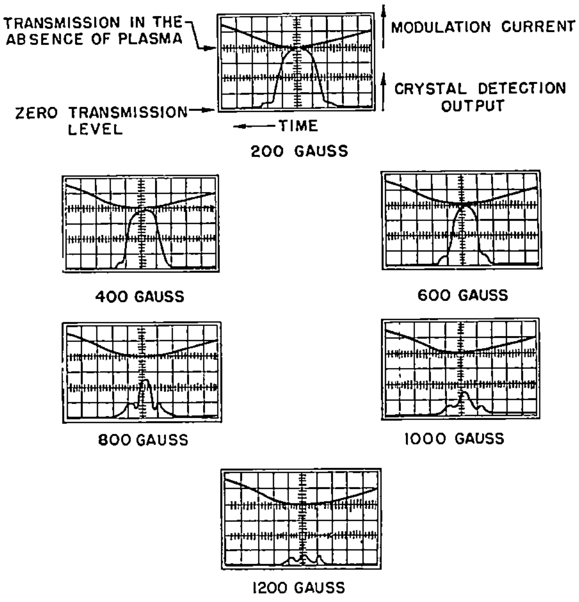

Fig. 3. Oscillograms showing the variation of modulation current and transmitted power during one de-ionization and ionization process for six different magnetic field values. (Reading from right to left, de-ionization occurs in time before ionization)

For this reason no attempt was made to infer that there were specific values of plasma frequency at the three resonant points. No claim can be made that the three resonances separated on the ω_p scale as ω_b was increased. However, the triple resonance phenomenon showed up very clearly and this was the principal goal of the experiment.

Considerable difficulty was experienced in obtaining the results shown in Fig. 3. It was found that the apparatus attained a considerable temperature due to heat generated in the plasma and in the winding of the d.c. magnet. This caused the collision frequency to increase to the point that the triple resonance effect was obscured as predicted by the data in Figs. 1 and 2. Indeed, when the apparatus was first turned on, the oscilloscope trace would clearly show a triple resonance, and as one watched, these features would subside until finally no resonance phenomena were displayed.

This difficulty would not necessarily be present in measurements on a plasma which was not supporting a large current. Often the collision frequency is small in problems concerning the plasma sheath around a missile, or the wake behind it, or in problems concerning the ionosphere. Such plasmas do not contain large currents and their exact laboratory stimulation must be accompanied by techniques different from the one used here. In such applications it can be expected that joint use of a d.c. magnetic field and electromagnetic waves can invoke a triple resonance effect which will prove useful in diagnostics.

Excitation of the 2*s* State of Atomic Hydrogen by Electron Impact

In a recent publication Kingston, Moiseiwitsch and Skinner[1] have applied the second Born approximation, retaining only terms up to the third order in the interaction energy, to the calculation of the total cross-section Q ($1s$–$2s$) for the $1s$–$2s$ excitation of hydrogen atoms by electrons Their results are displayed in Fig 1 Curve 1 is the cross-section obtained by using the first Born approximation while curves 4 and 6 are respectively the cross-sections given by the second Born approximation with allowance for (*a*) distortion due to the coupling to the $1s$ and $2s$ states, (*b*) polarization due to the coupling to the $2p$ states as well as distortion due to the $1s$ and $2s$ states

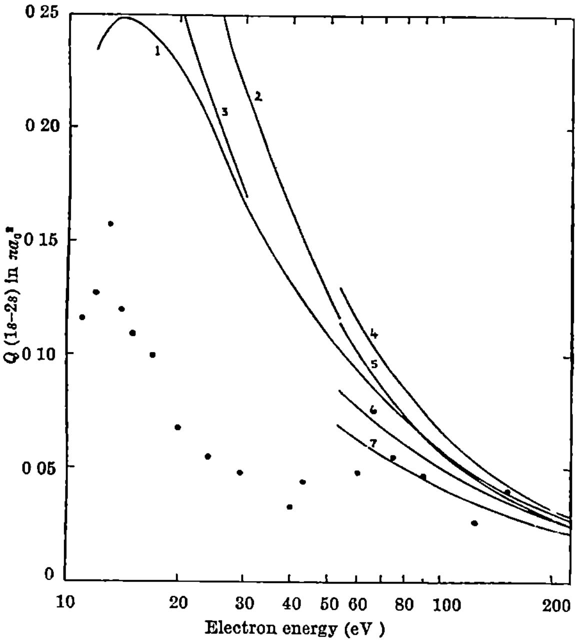

Fig 1

Wu[2] has reported first Born approximation calculations of Q ($1s$–$2s$) in which allowance for exchange has been made From the tables given by Wu the contribution resulting from exchange can be readily calculated and incorporated into the second Born approximation calculations of Kingston, Moiseiwitsch and Skinner The resulting cross-sections are displayed in Fig 1 Curve 5 includes the effects of distortion and exchange while curve 7 includes in addition the effect of polarization Allowance for exchange reduces the excitation cross-section Smith, Miller and Mumford[3] have carried out exact solutions of the coupled differential equations for the $1s$–$2s$ electron impact excitation of atomic hydrogen derived by making full allowance for the distortion due to the $1s$ and $2s$ states but neglecting exchange The cross-section obtained by them is given by curve 2 and is in satisfactory accord with the second Born approximation curve 4 calculated by Kingston, Moiseiwitsch and Skinner

Smith[4] has solved the coupled integro-differential equations for the s, p, d partial waves making full allowance for exchange as well as distortion The resulting total cross-section Q ($1s$–$2s$) is given by curve 3, the higher-order partial cross-sections having been estimated with the first Born approximation Curve 3 lies somewhat below curve 2, and thus allowance for exchange reduces the cross-section in agreement with the previously noted effect of exchange on the second Born approximation cross-sections

The experimental points of Stebbings, Fite, Hummer and Brackmann[5] for Q ($1s$–$2s$) are also displayed in the figure. Lichten[6] has shown that the original data of Stebbings *et al* are in error and should be multiplied by a factor 3/2 This correction was therefore introduced (cf Hummer and Seaton[7])

There is satisfactory agreement, at least at energies greater than 60 eV, between the modified experimental results of Stebbings *et al* and the cross-section curve 7 in which allowance for exchange as well as distortion and polarization has been included Noting that curve 4 lies slightly above curve 2, it is to be anticipated that curve 7 is slightly in excess of the actual $1s$–$2s$ excitation cross-section, which would then bring calculation into still closer agreement with the absolute experimental data of Stebbings *et al.*

The experimental cross-section obtained by Lichten and Schultz[8] does not extend above 45 eV, and in any event is not absolute Hence no comparison between theory and their experimental results is feasible However, their relative cross-section is in good agreement with the shape of the cross-section obtained by Stebbings *et al* as was pointed out by the latter authors

Measurement of Stopping-Power Ratio for Cavity Ionization Chambers

The energy absorbed in a medium per unit mass, E_m, exposed to X- or γ-radiation can be related to the ionization produced per unit mass of gas, J_m, situated in a cavity in the medium by the Bragg–Gray equation

$$E_m = \frac{1}{F_m} W J_m \qquad (1)$$

where W is the average energy associated with the production of one ion pair in the gas, F_m is the mass stopping-power ratio of the gas to the solid for electrons F_m has been evaluated theoretically by assuming electrons lose energy continuously[1,2] and also by allowing for discrete losses of energy[3,4] However, experimental investigation has shown that these theoretical treatments are only useful for a limited range of size of cavity[5], as indeed the initial assumptions in their derivations imply. In many situations the greatest uncertainty in measuring exposure or absorbed dose arises from uncertainty in this factor. Thus a direct measurement of F_m is desirable

Several workers have measured the relative stopping-power ratio, but Whyte[6] devised a method

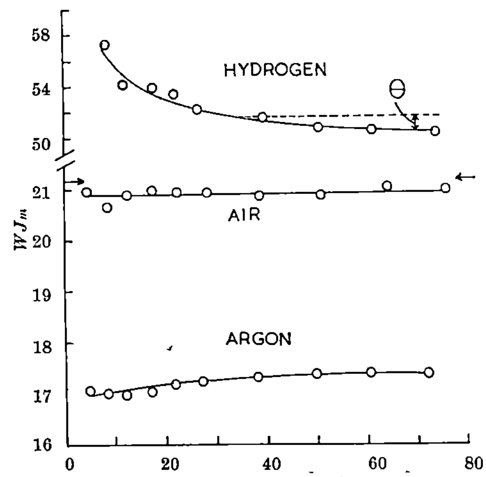

Fig. 1. Variation of the ionization/gm multiplied by the average energy associated with the production of one ion pair with the gas pressure in a graphite chamber irradiated by cobalt-60 γ-rays. θ is the change in the ionization/gm between 70 and 35 cm of mercury pressure

of measuring the stopping-power ratio absolutely by varying the air pressure in a series of ionization chambers with walls of different atomic number.

An absolute measurement of the stopping-power ratio can also be made by varying the pressure of different gases introduced into a single ionization chamber in the following way. Fig. 1 shows the variation in the ionization/gm of gas with the gas pressure for hydrogen, air and argon in a graphite ionization chamber irradiated by 1.25-MeV. photons (cobalt-60 γ-rays). The experimental technique has been described elsewhere[7]. Hydrogen with an atomic number less than graphite yields a graph with a negative gradient, while air and argon with an atomic number higher than graphite yield a graph with a positive gradient. The magnitude of the variation in the ionization/gm with the gas pressure increases with the magnitude of the difference between the atomic number of the gas and the wall and hence increases with the factor, F_m.

To measure this variation of the ionization/gm with the gas pressure a parameter, θ, has been chosen. θ is the change in the ionization/gm between 70 and 35 cm of mercury pressure. The value of θ for each gas is plotted against the value of WJ_m at 70 cm of mercury pressure for each gas in Fig. 2. Now if it were possible to fill the cavity with a gas exactly equivalent to the graphite wall, F_m would be unity at all gas pressures. Thus the ionization/gm would be independent of the gas pressure and in Fig. 1 a straight line parallel to the x-axis would result. In this case θ would be zero. It follows that the value of WJ_m in Fig. 2 where $\theta = 0$ is the value that would occur when the gas in the chamber is equivalent to graphite, namely, when $F_m = 1$.

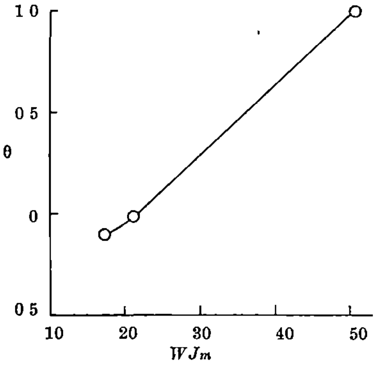

Fig. 2. Variation of the change in the ionization/gm with the ionization/gm multiplied by the average energy associated with the production of one ion pair

For the three gases used in this work W is known reasonably accurately and the values adopted are 36.3 eV for hydrogen, 33.8 eV for air and 26.1 eV for argon. From equation (1) it may be seen that F_m is proportional to WJ_m. In Fig. 1 the ionization/unit mass of gas has been multiplied by the appropriate value of W for each gas. Thus the ordinates in Fig. 1 are proportional to the stopping-power ratio, F_m. Now the value of WJ_m when $F_m = 1$ can be determined as described here and is represented by the arrows in Fig. 1. The absolute value of the stopping-power ratio, F_m, for any of the gases in graphite at a particular pressure is given by the ratio of the ordinate of the appropriate curve at that pressure to the ordinate of the arrows, for which $F_m = 1$.

The values of the stopping-power ratio, F_m, obtained in a preliminary investigation of the method were 2.39 ± 0.05 for hydrogen, 0.99 ± 0.02 for air and 0.82 ± 0.02 for argon for a 0.5-cm^3 cavity in graphite at atmospheric pressure irradiated by 1.25 MeV photons (cobalt-60 γ-rays). A more refined technique would considerably reduce the uncertainty quoted for these figures. In very accurate work it would probably be necessary to consider the effect of the transfer of slow electrons between the electrodes[8].

Although this method of measuring the stopping-power ratio requires data concerning W, it does offer the following advantages over Whyte's method: (1) gases are more easily interchanged than the chamber wall material; (2) there can be no errors arising from differences in volumes of the chambers as in Whyte's method; (3) to perform the interpolation in Fig. 2 it is obviously an advantage to obtain values of θ well above and well below $\theta = 0$. Thus, for example, to determine the stopping-power ratio for a graphite chamber containing air (a combination used frequently) materials are required with an atomic number, Z, well separated from the range $Z = 6$–8, as well as close to this range. By interchanging the wall materials Whyte's method is limited to conducting solids and therefore can only go down to beryllium ($Z = 4$). However, provided the appropriate relative values of W are available, this method can use hydrogen ($Z = 1$) and helium ($Z = 2$) both well separated from $Z = 6$–8. Above $Z = 6$–8 there are several suitable materials for both methods; (4) there can be no error arising from differences in the photon attenuation in the walls or from differences in the absorption coefficient of the wall materials.

I thank Prof. J. E. Roberts for his supervision and Dr. J. R. Mallard for his encouragement.

BIOPHYSICS

Estimation of Mass Thickness of Biological Samples from their Electron Micrographs

DURING the past several years a number of investigations[1-13] have been made to compute the mass thickness of biological samples, from the contrast in their electron microscope images The basis of all these measurements is the well-established relation

$$I_t/I_0 = \exp(-S.\ \rho t) \qquad (1)$$

where I_t/I_0 is the image contrast of an elemental object area of mass thickness ρt and S is the scattering cross-section per gm of the object By using carbonaceous samples, for example, spheres of polystyrene latex, of known diameter and density and measuring their image contrast, several authors[3,12] have estimated the value of S under various operating conditions of the electron microscope From these results, curve 1 in Fig 1 has been plotted, showing the variation of S with the angular aperture α, for 50-kV energy electron beam A few values of S for (i) carbon film calculated from the experimental data of Lippert[14] and (ii) 'Formvar' film (from data of Bahr[5]) have also been plotted in Fig 1

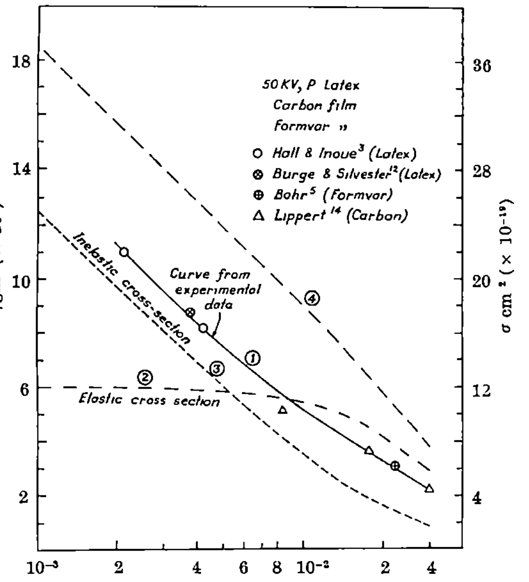

Fig. 1 Variation of scattering cross-section of carbonaceous samples for 50-kV electron beam

Considering the samples to be composed mainly of carbon, the scattering cross-section per atom is $\sigma = AS/N_A$, that is, 2×10^{-23} S cm ², and the same curve (1) represents σ versus α, with suitable change of scale in the ordinate

For comparison, the values of the elastic and inelastic cross-sections of the carbon atom, calculated from the electron scattering formula of Lenz[15] as modified by Sadhukhan[16], are shown as curves (2) and (3), while curve (4) represents the sum of the two cross-sections

The following conclusions can be drawn from these curves The scattering cross-section varies with angular aperture even in the range of 10^{-3}–10^{-2} radian, the nature of the variation indicates that the inelastic component of scattering seems to play an important part in the small angular region The experimental values of the scattering cross-section are not in quite satisfactory agreement with Lenz's equations Hence, any attempt to compute the mass thickness by making use of the theoretical electron scattering formula may give only the order of magnitude, but there is a possibility of a wide discrepancy as regards the right value

I wish to thank Prof N N Das Gupta for his kind interest in this work and Mr P Sadhukhan for helpful discussion Thanks are also due to the Ministry of Scientific Research and Cultural Affairs, Government of India, for financial assistance

RADIOCHEMISTRY

Isolation of Radioactive Bismuth from Metallic Lead and its Compounds

IT is self-evident that the isotopic radionuclide lead-210 will remain an inseparable part of the bulk lead metal which is produced during the extraction of this metal from its various mineral ores

This lead isotope, having a half-life of 22 years, is a direct daughter product of the radium decay chain, and is a natural precursor of bismuth-210, the latter radionuclide decaying by β-decay to the α-emitting polonium-210

$$\begin{array}{ccccc} {}^{210}\text{Pb (Ra}D) & \xrightarrow{\beta} & {}^{210}\text{Bi (Ra}E) & \xrightarrow{\beta} & {}^{210}\text{Po (Ra}F) \\ \text{22 years} & & \text{5 days} & & \text{138 days} \end{array}$$

It has been established experimentally that factual information regarding the concentration of various radioactive isotopes in normal samples of metallic lead may be obtained by the radiochemical separation and determination of the bismuth isotope This is achieved in a quantitative manner by the acidic dissolution of 10–20 gm of the lead material, adding approximately 10 milligrams of bismuth as carrier in the form of the nitrate, and precipitating the bismuth with an *n*-propyl gallate solution in 0 01 normal nitric acid solution at boiling point The yellow crystalline precipitate formed consists essentially of the salt, $C_{10}H_9O_5$ Bi H_2O (molecular weight =436 188), and contains 0 4790 gm bismuth per gm of precipitate dried at 110° C

In experimental practice, the precipitate may be adequately dried by washing with ethanol with suction prior to weighing During the present experiments the filtration was carried out on a

Whatman 541 filter paper of 22 mm diameter, this being mounted on a 1-inch aluminium planchet and counted under a conventional end-window Geiger tube

Alpha particles from any contaminating polonium-210 would be satisfactorily excluded by the Geiger window

Extrapolation of the count-rate to zero time (time of precipitation) shows that the emission decays with the characteristic half-life of 5 days, thus positively identifying the bismuth-210 isotope Typical experimental data are illustrated graphically in Fig 1

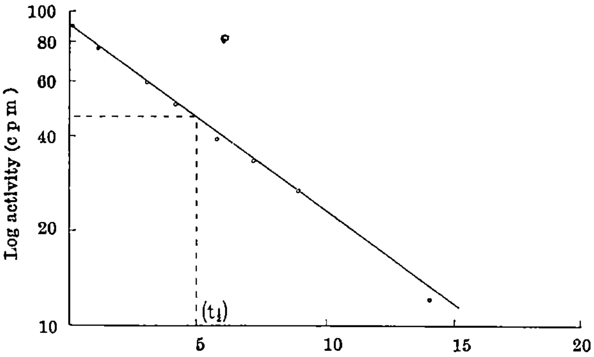

Fig 1 Decay curve of bismuth-210

The count-rates are related on a quantitative basis with those given by a standard solution of radium D, E, F, from which bismuth has been precipitated in the same way The chemical yield of the precipitated bismuth is invariably 100 per cent

Table 1 gives some of the results of these investigations on various samples of lead and its oxides It may be noted that sample No 280 was carefully counted using an anti-coincidence type Geiger assembly, whereas all the other samples were done by normal Geiger tube counting

Table 1 RADIOACTIVITY OF SAMPLES OF LEAD

Laboratory No.	Lead sample	Bismuth-210 β-activity $\mu\mu$c /gm	Total α-activity $\mu\mu$c /gm

295	Virgin lead	2 3 ± 0 1	4 3 ± 1 0

* 90 per cent confidence limits, errors on counting only

The order of radioactivity shown is less than the figure of 20 µµc /gm , which is the proposed limit for natural lead given in the Radioactive Substances Act, 1960 (Sec. 18, Schedule III)

W E Grummitt *et al* [1], by an alternative method, quote the figures of 0 17 µµc total β-activity per gm for sixteenth-century lead, and 1 7 µµc /gm for modern lead These values are in complete accord with those obtained by the bismuth method in the present investigation

In the final column of Table 1, experimental values are given for the total alpha activity of the individual lead samples used These activities were determined by counting infinitely thick sources in a scintillation counter and comparing the results with those obtained from an artificially prepared lead standard containing a known amount of radium D in equilibrium with its daughter products This was prepared by precipitating inactive lead sulphide in the presence of a known amount of radium D, E, F, and the $Z^{2/3}$ relation of J L Glasson[2] was used for correcting the results for the lead compounds of different average atomic number to the lead sulphide standard

The numerical agreement between the measured alpha and beta activities in the final and penultimate columns of the table strongly suggests that the equilibrium product, polonium-210, is the main α contaminant in commercial lead samples, and that radium and other emitters can only be present in small concentrations

The method described in this paper for the separation of bismuth radionuclides from abundant lead has many obvious applications which are now being explored in this Laboratory

In a recent paper presented by A Turkovitch *et al* [3] it was shown that radioactivity induced in the lead sheath of the recovered satellite *Discoverer XVII* by solar-flare on November 12, 1960, was largely due to the production of the 15-day bismuth-205 which emits X-rays in the 70-keV region

Separation was carried out by the electro-deposition of bismuth carrier on a platinum electrode immersed in the lead electrolyte obtained by acid dissolution of the satellite sample (cf A D R Harrison *et al* [4])

It may be confidently predicted that the method now described here could be usefully employed in satellite investigations of this character, and would afford a radiochemical alternative to the electrochemical method of separation

It may be mentioned that occasionally samples of lead are naturally contaminated with inactive bismuth, and where this occurs, the appropriate correction must be applied for the radiochemical yield

CHEMISTRY

Radiation Effects on Lithium-doped Nickel Oxide Catalysts in Carbon Monoxide Oxidation

EFFECTS of nuclear radiation on heterogeneous catalysts has been the subject of various investigations in the past few years[1,2] These investigations have shown that significant changes due to irradiation are produced in the catalytic behaviour of some oxides and metals The phenomenon is due to the fact that catalytic activity is strongly dependent on the structure of solids and this structure may be modified on irradiation Nuclear radiations may create in semi-conductors new energetic levels, which change the position of the Fermi-level in the solid This leads to changes in various structural sensitive properties, for example, the activation energy of the reaction catalysed by the surface of the solid[3]

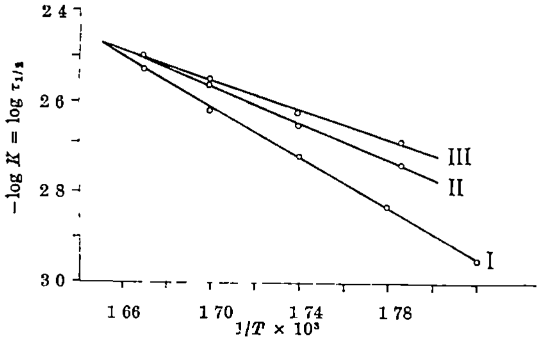

Fig 1 Arrhenius plot for catalytic oxidation of CO on NiO + Li_2O catalyst before (I) and after (II) 80-hr irradiation in the nuclear reactor and after one further irradiation (III) of 80 hr Catalyst NiO + 2 5 mol per cent Li_2O

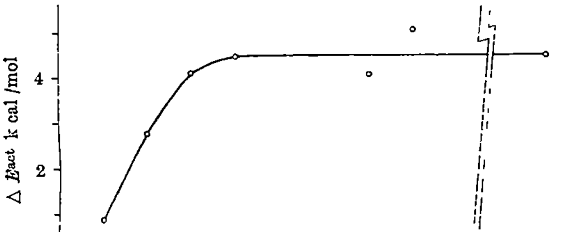

Fig 2 Activation energy differences ΔE_{act} (before and after irradiation) versus irradiation time

However, the major part of the cited papers deals with the variation of the reaction-rate after irradiation at a given reaction-temperature, and only in three papers are there presented results about variation of the activation energy[4–6]. In our opinion, from the changes in the activation energy following irradiation one can get more information about how irradiation affects catalytic behaviour of solids and, on the other hand, how to correlate the change of catalytic and electrical properties via activation energies

In the present communication, we present the results of radiation effects on catalytic behaviour of solid solutions of nickel oxide (NiO) and lithium oxide (Li_2O) in carbon monoxide oxidation The choice of NiO was determined by the fact that its electrical and catalytic properties are better known, so that it is easier to give an interpretation of the experimental results Doping with lithium enhances the efficiency of nuclear radiations through the reaction $Li(n,\alpha)^3H$ Thus, in the neutron flux the lithium atoms become an important source of internal irradiation On the other hand, the results of the catalytic oxidation of carbon monoxide (CO) yield more reproducible results on NiO + Li_2O than on pure NiO (ref 7)

The effects of thermal neutron irradiation of NiO + Li_2O catalysts for the decomposition of nitrous oxide (N_2O) have been examined by Saito *et al* [6], but this work does not indicate a clear variation of the activation energy

Our experimental conditions were the following irradiations were made in the thermal column of the *VVR–S* 2,000 kW water-cooled and water-moderated enriched uranium reactor of the Institute of Atomic Physics, Bucharest The fluxes were thermal neutrons 2×10^{11} *n* /cm ^{2} sec , and fast neutrons 7×10^9 *n* /cm ^{2} sec

The catalyst samples were obtained from the pyrolysis of $Ni(NO_3)_2$ The NiO powder was mixed with Li_2O (from Li_2CO_3), in proportion of 2 5 mol per cent, and sintered at 850° C for 3 hr The oxidation of carbon monoxide was followed in a closed system[7] as indicated by Dry and Stone[8] The results of a typical experiment are represented in Fig 1 Fig 2 shows the variation of the activation energy differences (before and after irradiation) versus irradiation time From these figures, it is clear that irradiation significantly affects the activation energy of the catalytic oxidation of carbon monoxide and that the effects increase with increasing irradiation time The experimental values from Fig 2 seem to imply the existence of a saturation effect revealed by a plateau beginning with irradiation times of the order of 40 hr

Hydrogen Overvoltage at Cathodes of 77 per cent Palladium and 23 per cent Rhodium

CATHODIZING an equilibrium Pd/H/H_2 electrode (25° C 1 atm hydrogen zero volt potential with respect to a Pt/H/H_2 reference in the same solution) further increases its hydrogen content (H/Pd, atomic ratio) and its corresponding hydride vapour pressure *p*. These increases are reflected as a component of overvoltage (volts) given[1–3], the symbols η_2 or η_d (termed[1,3] the diffusion or hydride overvoltage) and related to *p* by $\eta_2 = 0\ 029 \log p$ The large capacity of palladium for hydrogen has enabled η_2 to be obtained by extrapolation, back to zero time, of the increase of electrode potential, *E*, which follows interruption of cathodization, using established relationships between *E*, *p* and H/Pd (refs 1–3) From such measurements it has been established[1,3–5] for surfaces active for rapid equilibration with hydrogen molecules dissolved in solution that at current densities *i* less than 0 040 amp cm $^{-2}$ the retarding kinetic step maintaining H/Pd in excess of its equilibrium value (1 atm hydrogen 25° C) is the slow diffusion from the cathode of hydrogen molecules formed during electrolysis Under these conditions, η_2 is related to *i* by

$$\eta_2 = 0\ 029 \log \left(\frac{i + i_0}{i_0}\right) \qquad (1)$$

where under conditions of vigorous stirring $i_0 \sim 3$ m amp cm $^{-2}$ The observation[1–3] that η_2 attains an almost constant value for *i* greater than 0 040 amp cm $^{-2}$, when hydrogen is evolved as bubbles, has been associated[1] with either critical supersaturation of the diffusion layer with dissolved molecules or saturation of chemisorption sites Experiments reported here appear to eliminate the latter possibility.

The general effect of increasing the amount of rhodium in the Pd–Rh–H system (ref 6 and unpub-

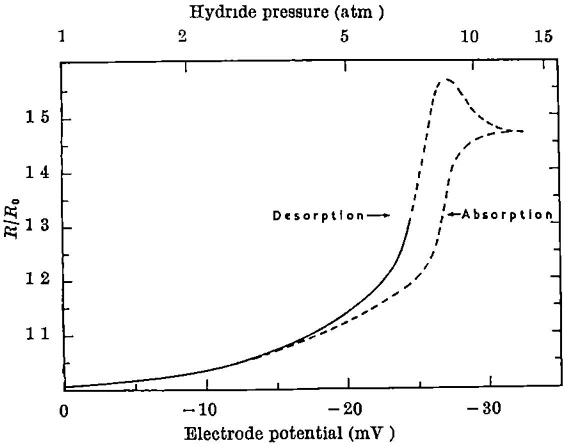

Fig. 1

lished results) resembles that of platinum in the Pd–Pt–H system[8] in increasing the hydride vapour pressure over regions where α- and β-phase hydrides co-exist (and the solids can show marked changes in hydrogen content) and is paralleled (unpublished results) by changes in electrical resistance (recorded as R/R_0 where R_0 is the resistance of the hydrogen-free alloy). Relevant relationships (25° C.) for the 23 per cent rhodium (by weight) system are shown in Fig. 1, where the desorption data were estimated with specimens of slightly less than homogeneously diffusion-controlled activity (see later). Cathodes were in the form of wire (0·0122 cm. diameter, about 10 cm. long) and the apparatus has been described[7]. R/R_0 was recorded, in conjunction with electrode potential both during and subsequent to cathodization, using an a.c. bridge[8] and measurements carried out in 0·002 N and 0·01 N hydrochloric acid to avoid complications due to solution-conduction of the bridge current[7,8]. Pre-activation was either (i) by pre-flaming at close to white heat, or (ii) by plating palladium black from aqueous palladium chloride, or (iii) by plating 'bright' palladium from aqueous tetramminepalladous nitrate under conditions recommended by Philpott[9]. All electrode potentials were zero in hydrogen-saturated solutions prior to cathodization.

As anticipated, values of η_2 (from steady-state values of R/R_0) attained by palladized specimens were in accord with equation 1 for $i \leqslant 0·020$ amp. cm.$^{-2}$ ($\eta_2 \sim 26$ mV.). Furthermore, in support of Knorr's contention[5] that the overvoltage at all platinum group cathodes (homogeneously activated) should be generally governed by the rate of diffusion of hydrogen molecules from their surfaces, pre-flamed specimens could be easily prepared which obeyed equation 1 in this range of i, not only attaining virtually identical steady-state values of R/R_0 to palladized specimens for the same i but also exhibiting virtually identical rates of decrease of $|E|$ and R/R_0 on interruption of cathodization. When $i \sim 0·050$ amp. cm.$^{-2}$, dense clouds of tiny bubbles began to evolve from all cathodes with surfaces sufficiently active for η_2 to be given by equation 1 at lower current densities with palladized specimens, η_2 could thereafter be increased little further, since R/R_0 never exceeded 1·2 even on increasing i to 0·260 amp. cm.$^{-2}$ (equation 1 giving $\eta_2 \sim 56$ mV.), in one specimen R/R_0 was constant at 1·13 from 0·050 to 0·260 amp. cm.$^{-2}$. These results were not the consequence of insufficient chemisorption sites, however, because $R/R_0 \sim 1·4$ was rapidly attained both by less surface-active pre-flamed specimens (even for $i < 0·020$ amp. cm.$^{-2}$) and also by cathodes which had been quite thickly coated with bright palladium but which exhibited, after interruption of electrolysis, only slightly slower rates of decrease of $|E|$ and R/R_0 (over comparable ranges of values) than cathodes for which R/R_0 was not found to exceed 1·2.

It is difficult to measure differences, resulting from hysteresis over the region of co-existence of α- and β-phase hydride (unpublished results) between the absorption/desorption relationships (Fig. 1), so that the precise value of η_2 during cathodization must be assessed with caution. So far, however, results suggest that the limiting hydride vapour pressure, and thus the pressure of dissolved hydrogen molecules in the diffusion layer, can be as low as 10 atm., which is slightly less than that indicated from work with pure palladium[1,3]. In further experiments with this and other palladium alloys, it is hoped to define these limiting pressures even more precisely.

We are indebted to the International Nickel Co. (Mond), Ltd., for providing the palladium/rhodium alloy.

Kinetics of Dissociation of Ethyl Halides in Self-quenching Geiger–Müller Counters

By using the experimental procedure described in ref. 1 mass-spectrometric work on electron-impact dissociation of ethyl halides C_2H_5X (X = Cl, Br, I) in a working Geiger–Muller counter has been carried out.

Simple analysis of the respective decay diagrams shown in Fig. 1 leads to the conclusion that, as in the case of saturated hydrocarbons, a regular, essentially first-order, slow decomposition process follows an initial very fast consumption of parent molecules which practically comes to an end after the

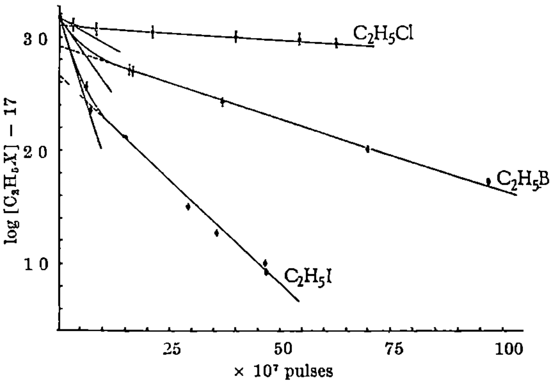

Fig. 1. Decay curves of ethyl halides used as quenching vapours

first 10^7–10^8 pulses have been registered by the counter It is interesting to note that from our mass-spectrometric data evidence was obtained that in the case of ethyl iodide the large initial loss of quenching parent molecules amounts to about 98 per cent For both ethyl chloride and bromide the respective values lie between 85 and 50 per cent

Assuming that the observed fast consumption process is due primarily to strong adsorption phenomena occurring on freshly degassed electrode and glass surfaces, it seems reasonable to expect that only very few undecomposed parent molecules will reach the wall of the counter The average life-time before decomposition for an excited polyatomic molecule is less than 10^{-13} sec (ref 2) The time required by the same molecule to reach the critical distance from the wall (where the probability of neutralization equals unity) being about 10^{-12} sec , it may be assumed that only about one in 10^9 molecules of ethyl halide can reach the cathode surface before decomposing Furthermore, it is apparent that heavy organic molecules such as ethyl halides have a large probability of pre-dissociating at all energies

In order to illustrate the primary decomposition of excited ethyl halide molecules or ions in a working Geiger counter use may be made of the following scheme

$$\begin{array}{ccccc} (M^0, M^+)^* & \underset{k'_i}{\overset{k_i}{\rightleftharpoons}} & (R^0{}_i, R^+{}_i) & + & (R^+{}_j, R^0{}_j) \\ & & \downarrow k_{R_i} & & \downarrow k_{R_j} \end{array}$$

where M^0 and M^+ are parent molecules or their ions, R_i and R_j—free radicals, the usual primary decomposition products, k_i and k'_i—the decomposition and recombination-rate constants, k_{Ri} and k_{Rj} rate-constants of subsequent free-radical secondary reactions

If the concentration of the molecular species M^0 and M^+ is denoted by $[M]$ and those of $[R^0{}_i + R^+{}_i]$ and $[R^0{}_j + R^+{}_j]$ by $[R_i]$ and $[R_j]$ respectively, then

$$\frac{\mathrm{d}[M]}{\mathrm{d}n} = k_i[M] - k'_i[R_i][R_j]$$

Now, at the beginning of the rapid-loss portion of the decay curve it may be assumed that $[M] \gg [R_i][R_j]$ which leads to a first-order equation for the rate of disappearance of parent molecules from a fresh quenching gas

$$\frac{\mathrm{d}[M]}{[M]} = k_i \mathrm{d}n$$

where n is the total number of counts registered by the scaling unit The straight lines, tangent to the decay curves at their origins, shown in Fig 1, represent the kinetics of the initial decomposition of the respective quenching agents It need scarcely be said, however, that with continued use of the counter, the composition of its quenching gas is steadily changing The main features involved are the recombination of free radicals to form a wide assortment of heavier molecules and the adsorption-desorption equilibrium Hence the over-all decay rate-constant is gradually approaching the k_p^s value of the first-order slow-decomposition process

Table 1 QUENCHING CHARACTERISTICS OF ETHYL HALIDE VAPOURS

Quenching molecules	C_2H_5Cl	C_2H_5Br	C_2H_5I
Filling pressure (at 298°) in mm mercury	60	60	60
Counter volume (ml)	71 2	71 2	71 2
Cathode	graphite	graphite	copper
Average No of electrons/ pulse, $\times 10^{-8}$	2 75 ± 0 27	7 2 ± 0 72	17 2 ± 1 7
Initial rapid decomposition rate-constant $k_p^r \times 10^9$/ pulse	5 06	13 2	29 2
Initial rapid decomposition rate-constant $k_e^r \times 10^{17}$/ electron	1 84 ± 0 18	1 83 ± 0 18	1 70 ± 0 17
Initial specific electron yield $S_e \times 10^{-3}$ molecules/ electron	2 7 ± 0 3	2 7 × 0 3	2 55 ± 0 26
Slow decomposition rate-constant $k_p^s \times 10^9$/pulse	0 55	2 76	8 74

The calculated rate-constants for both the initial rapid loss and the subsequent slow decomposition of C_2H_5X molecules are shown in Table 1

Space Group and Unit Cell of the *m*-Bromobenzoate of Photoisopyrocalciferol

THE unit cell and space group of the *m*-bromobenzoate of photoisopyrocalciferol have been determined, and an X-ray diffraction investigation with three-dimensional data is in progress Dauben and Fonken[1] have postulated a structure for photoisopyrocalciferol based on chemical and spectroscopical investigations The *m*-bromobenzoate has been prepared with a chemical analysis of C 72 23 per cent, H 8 17 per cent, and Br 13 58 per cent compared with the calculated values of C 72 52 per cent, H 8 17 per cent, and Br 13 79 per cent for the $C_{35}H_{47}O_2Br$ molecule The crystals melt over the range 93 5–95° C The crystals are colourless, flat needles with the long dimension parallel to the b axis The a axis is perpendicular to the flat sides of the needles Weissenberg photographs of the type hnl and $hk0$ have been taken showing systematic absences only of the type $0k0$ with k odd The usual intensity relationships for the monoclinic system are observed The space group $P2_1$ is the only one consistent with the above observations and compatible with the asymmetrical molecules The following cell dimensions have been determined from films calibrated with quartz powder patterns $a = 21\ 13$ Å., $b = 7\ 39$ Å , $c = 10\ 35$ Å , $\beta = 92°\ 14'$

The density calculated from the above cell dimensions assuming two molecules a cell of 1 19 gm /c c compares favourably with the density of 1 17 gm /c c determined by flotation methods

A grant from the Research Corporation for equipment has made this preliminary work possible and is gratefully acknowledged

Alkali Metal Titanium Oxide Bronzes

THE crystallographic relationships between $K_2Ti_2O_5$, $Na_2Ti_3O_7$ and $Na_2Ti_6O_{13}$, the structures of which have been determined by us[1], led to the belief that oxide bronzes with host lattices of formula TiO_2 might be induced to form under reducing conditions

The reduction in hydrogen of coarsely crystalline $Na_2Ti_3O_7$ for two days at 950° C , followed by extraction with hot sulphuric and hydrofluoric acids, led

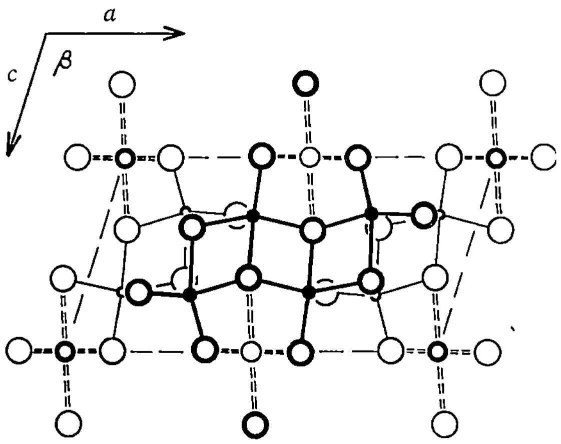

Fig 1 The structure of Na_xTiO_2 seen in projection on to (010) The smaller circles are titanium, the intermediate ones are sodium, and the largest oxygen The heavier outlined atoms are at the level $y = 0$, the lighter at $y = \frac{1}{2}$ The sodium–oxygen bonds are drawn as broken lines, and the unit cell is shown in outline

to the isolation of opaque, blue-black electrically conducting crystals with the empirical formula Na_xTiO_2 (x approximately equal to 0 2) The symmetry is monoclinic, and the unit cell dimensions are $a = 12\ 146$, $b = 3\ 862$, $c = 6\ 451$ Å., $\beta = 106\ 85°$, space group $C2/m$ The structure, deduced by trial and error and refined by Fourier methods as well as by a least squares treatment, is shown as a projection in Fig 1 The titanium atoms each have a distorted octahedral grouping with oxygen, and the octahedra themselves share edges to form a double sheet which, in Fig 1, is parallel to the a axis These sheets are joined together by corners and this results in a new structure of formula TiO_2 The Ti—O bonds vary between 1 7 and 2 2 Å with an average of 1 97 Å, and the oxygen–oxygen distances range from 2 4 to 3 2 Å, average 2 76 Å

This host lattice contains within it interstitial positions which are occupied, in part only—and at random—by sodium ions each of which has four bonds to oxygen of 2 5 Å and four longer ones 3 0 Å Ideally speaking these positions would be cubic, but the distortions introduced by the irregular Ti—O octahedra force the sodium to adopt a virtually rectangular planar configuration

In a discussion of the crystal chemistry of the vanadium oxides, the possibility of structural homologues with the general formula $Me_{2n}O_{5n-2}$ was pointed out[2], V_6O_{13} ($n = 3$) and V_2O_5 being the only members known at that time It is now interesting to note that the host lattice of this sodium titanium bronze, while having a different metal ion, nevertheless has the structure of the end member of the series, $n = 2$

Blue fibrous needles of K_xTiO_2 (x approximately 0 13) were formed by the reduction of $K_2Ti_2O_5$ under identical conditions The tetragonal unit cell dimensions were $a = 10\ 172$, $c = 2\ 846$ Å, the indices showing pseudo body centring None of the needles proved to be a single crystal, and a further detailed investigation by us is not contemplated The structure of this substance is undoubtedly related to that of the mineral hollandite which, however, is truly body-centred tetragonal or monoclinic[3] This structural type, previously considered to be capable of occurring as chemical compounds with bronze-like characteristics[4], is one containing continuous linear interstices, or tunnels, which enclose variable numbers of ions such as barium, potassium, or lead, all of which are considerably larger than sodium The host cation may be one or other of the quadrivalent elements manganese, as in hollandite itself, or titanium[5] The minor symmetry anomaly which alone distinguishes it from these published data possibly could involve order and disorder of the potassium ions in the tunnels

One other titanium bronze, La_xTiO_3 ($0\ 7 < x < 1\ 0$), has been recorded, and this is isomorphous with the cubic tungsten bronzes with the perovskite structure[6] Thus it bears little relationship to either of the two briefly described here

We are indebted to Mr E S Pilkington for the chemical analyses

BIOCHEMISTRY

Formation of 2,3-Dihydroxybenzoic Acid in Fermentation Liquors during the Submerged Culture Production of Lysergic Acid α-Hydroxyethylamide by *Claviceps paspali* Stevens and Hall

A STRAIN of *Claviceps paspali* Stevens and Hall has previously been shown to be capable of producing lysergic acid α-hydroxyethylamide in submerged fermentation[1,2]. Examination of chromatograms (solvent n-butanol/acetic acid/water, 4 1 5) of culture fluids at the end of the fermentation period revealed the presence of a mobile (R_F 0 83) spot showing bright blue fluorescence, not giving the Ehrlich–Van Urk reaction for lysergic acid derivatives but giving a blue-violet colour with ferric chloride

The substance responsible for this spot could be extracted from the culture medium acidified with concentrated sulphuric acid with two volumes of ether and was obtained crystalline after transfer to water at pH 4, re-extraction with ether at pH 1, washing the ether extract repeatedly with water and evaporating to dryness It was recrystallized from water The yields were of the order of 200–350 mgm. from 1 litre of culture medium, showing that the substance is a metabolite of major importance in the lysergic acid fermentation by *Claviceps paspali* Stevens and Hall It gave a strong blue-violet colour with ferric chloride which turned red on alkalinization with sodium hydroxide It analysed for $C_7H_6O_4$ (C, 54 65, H, 3 92 per cent, calc C, 54 52, H, 4 01 per cent) and was identified as 2,3-dihydroxybenzoic acid by comparison with an authentic sample by chromatographic behaviour in three solvent systems as well as by its ultra-violet and infra-red spectrum, its melting point (200° C), mixed melting point (no depression) and its first dissociation constant (found $1 1 \times 10^{-3}$)

2,3-Dihydroxybenzoic acid is also formed from l-tryptophan by washed mycelium of *Claviceps paspali* Stevens and Hall in replacement cultures and clearly is one of its breakdown products in this micro-organism To our knowledge, 2,3-dihydroxybenzoic acid has not been identified as a product of tryptophan degradation in any other tryptophan derivative synthesizing micro-organism It has, however, been shown to be formed from salicylic acid in *Aspergillus niger*[3], and in the rat[4], and to occur in Nature in the buds of *Populus balsamifera*[5] and as a glucoside in the leaves of *Vinca minor*[6].

Identification of an Amylobarbitone Metabolite in Human Urine

Amylobarbitone (5-ethyl-5-(3-methylbutyl) barbituric acid) fed to dogs in doses of 45 mgm. per kgm has been shown to produce 5-ethyl-5-(3-hydroxy-3-methylbutyl) barbituric acid as the main metabolite, about 67 per cent of the original dose being excreted in this form[1]

We have recently identified this metabolite in the urine of a woman who had died 30 hr after ingesting an unknown quantity of 'Tuinal' (equal parts of amylobarbitone and quinalbarbitone)

The metabolite was obtained by saturating the urine with ammonium sulphate, acidifying with hydrochloric acid, and continuously extracting with ether for 8 hr A 0 5 *N* ammonium hydroxide extract of the ether was acidified with hydrochloric acid, saturated with ammonium sulphate, and re-extracted with a large volume of ether The ether was evaporated, and the residue dissolved in a small volume of alcohol, which was spotted on Whatman No 1 chromatography paper The paper was developed in *n*-butanol/0 880 ammonia (3 1) for 4 hr

After exposing the paper to ammonia vapour, four absorbing spots were detected with R_F's 0 65, 0 18, 0 08 and 0 respectively using ultra-violet light (2537 Å). A permanent record was obtained by contact printing the ammonia-treated paper chromatogram using Ilford 50 reflex paper and the same ultra-violet source[2] (Fig 1)

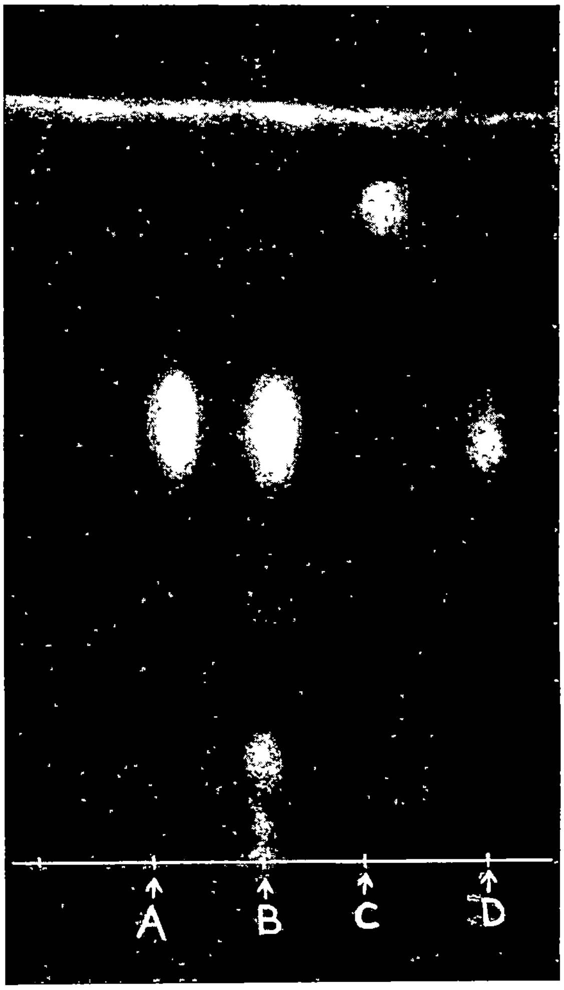

Fig 1 Chromatogram developed in butanol–ammonia *A*, 5-Ethyl-5-(3-hydroxy-3-methylbutyl) barbituric acid, *B*, total urine extract, *C*, amylobarbitone, *D*, eluted R_F 0 65 metabolite Ultra-violet transmission photograph after exposing chromatogram to ammonia vapour

The highest of the spots had the same R_F as a synthetic sample of 5-ethyl-5-(3-hydroxy-3-methylbutyl) barbituric acid run adjacently None of the spots corresponded with amylobarbitone The substances with R_F's 0 65 and 0 18 gave purple colours after spraying with cobalt chloride (1 per cent in acetone) and exposing to ammonia vapour[3] and were the only ones showing greatly increased absorption after ammonia vapour treatment, indicating an intact pyrimidine ring

The R_F 0 65 urine metabolite was eluted with alcohol acidified with hydrochloric acid, and the X-ray

Table 1 *d*-Values of 5-ethyl-5-(3-hydroxy-3-methylbutyl) Barbituric Acid

d-Value	Intensity	*d*-Value	Intensity
9 82	20	4 225	10
8 865	80	3 525	40

Chromatography and Nucleotide Sequences of Deoxyribonucleic Acid synthesized in *Salmonella typhimurium* after Irradiation with Ultra-Violet

IT has been shown[1,2] that ultra-violet irradiation produces in some kinds of bacteria, for example, *Escherichia coli* B/r and *Salmonella typhimurium*, a temporary inhibition of deoxyribonucleic acid (DNA) synthesis The synthesis is resumed after 30–60 min and proceeds at a rate similar to the control, but the surviving bacteria are growing only in mass, having lost their ability to form colonies One of the possible explanations for such behaviour is that DNA synthesized after temporary inhibition is different from the normal one That this might be so is supported by Kanazir *et al* [3], who found that whereas DNA from non-irradiated *Sal typhimurium* could reduce the damage to an irradiated culture, that from an irradiated culture could not, and by Hudnik and Glisin[4], who showed that the thermal denaturation pattern followed by viscosity and ultra-violet absorption measurement was different in the two DNA's

Ord and Stocken[5] using the usual analytical procedures were unable to distinguish between DNA of thymus from normal and irradiated animals, but a difference could be established by chromatography on 'Ecteola' columns according to the method of Bendich *et al* [6] The same method was therefore used for characterization of DNA from normal and irradiated *Sal typhimurium*

The growth of bacteria and the irradiation conditions were the same as described in ref 3 At zero time one-half of the bacteria were irradiated with an LD_{50} dose of ultra-violet light delivered from Hanovia mercury vapour lamp and phosphorus-32 (1 μc /ml culture) added 120 min later At this time there is reason to suppose that the bacteria are synthesizing DNA at the same rate as their controls Phosphorus-32 was added to the control bacteria 90 min. from zero time and both irradiated and control samples were gathered 90 min after the addition of phosphorus-32 They were then washed and DNA isolated according to the method of Zamenhof[7] using 15 per cent 'Dupanol' for the lysis of the cells Ribonucleic acid (RNA) was removed by digestion with ribonuclease and ethoxyethanol precipitation as described by Kirby[8] The possible contamination with RNA was checked by measuring radioactivity in the supernatant after digestion of the DNA with alkali No radioactivity could be detected in this fraction The protein content was less than 0 5 per cent when tested according to Lowry[9]

Chromatography on 'Ecteola' was performed as described by Ord and Stocken[5] Two mixing chambers in series were used for gradient elution and the elution pattern followed by measurement of optical density at 260 mμ The control and irradiated samples of DNA were eluted in parallel from the common supply of solvent The fractions were pooled and analysed for radioactivity in a liquid Geiger counter and for DNA by the method of Ceriotti[10]

Nucleotide sequences were estimated according to the method of Burton and Petersen[11] on unlabelled DNA samples prepared in the same way as described here

If the amount of ultra-violet absorbing material eluted in the main fractions in the control and irradiated DNA are compared (Table 1) it can be seen that more is eluted in the irradiated DNA in fractions I*A*, *B* and III and less in fractions II and IV, as compared with the control Although small, the differences are consistent in both experiments

Table 1 CHROMATOGRAPHY ON 'ECTEOLA' OF DNA FROM NORMAL AND ULTRA-VIOLET IRRADIATED *Salmonella typhimurium*

Fraction	E_{260} as percentage of control Exp 1	 Exp 2
1 *A*	119	127
1 *B*	104	105
2	90	79
3	103	104
4	86	89

Fig 1 represents the specific activities of pooled sub-fractions plotted against the composition of the eluant It can be seen from the elution pattern that the radioactive fractions of the irradiated DNA start with the elution at a lower concentration of sodium chloride, and that the specific activities of the fractions eluted with sodium chloride gradient are higher in the irradiated DNA It is difficult to see why this is so since both control and irradiated bacteria synthesize practically the same amount of DNA in the same time It is possible that although the net synthesis is roughly the same in the two cases, the DNA formed in the irradiated bacteria is less stable[12] and the turnover correspondingly greater There are smaller differences in the subsequent fractions, and at the end of ammonia

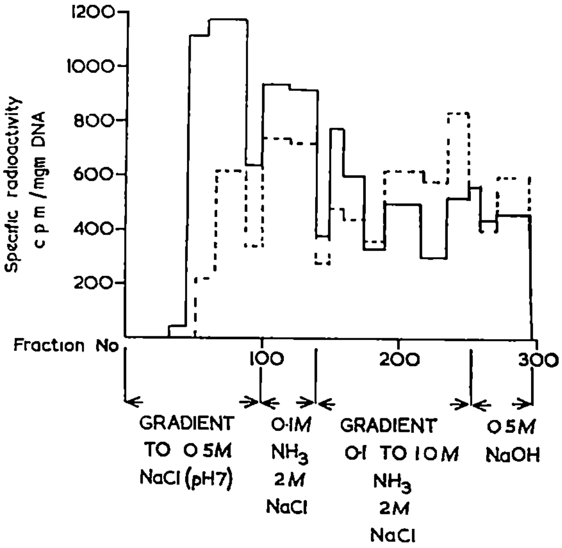

Fig 1 Specific activities of DNA fractions (*Salmonella typhimurium*) eluted from 'Ecteola' – –, Control, —, irradiated

gradient and in the sodium hydroxide sub-fractions the specific activity of the irradiated DNA is lower than that of the control

The results of the estimation of frequencies of some nucleotide sequences are summarized in Table 2 No difference was found in the frequency of the following sequences C, T, T_3p_2, T_4p_3, T_5p_4, CT_5p_5, T_3Cp_3 and C_2Tp_2 But some of the nucleotides containing more cytosine appear to be more frequent in the irradiated DNA while some nucleotides with more thymine seem to be more frequent in the control It will be noted that the TpC/CpT ratio is changed from 1 33 to 1 16 and this adds further support for the idea that irradiation has modified the structure of the DNA (cf Burton[13]) Relevant to this are the observations of Beukers and Berends[14], who found a dimerization of thymine which had been exposed to ultraviolet irradiation *in vitro*, and of Wacker *et al* [15], who noted a change in 2^{14}C-thymine of bacterial DNA irradiated *in vivo*

Table 2 NUCLEOTIDE SEQUENCES OF DNA FROM NORMAL AND IRRADIATED *Salmonella typhimurium*

Determination of Argininosuccinic Acid by Ion-Exchange Chromatography

RECENTLY, an unknown amino-acid excreted in the urine by two mentally defective children[1] was identified as argininosuccinic acid (ASA)[2] This is unstable in weakly acid aqueous solutions and cyclizes[3] More recently Westall[4] has shown that under these conditions two separate types of anhydride (*B* and *C*) are formed, rapidly at high but more slowly at room temperatures

For the original metabolic studies of ASA in the mentally defective children[5], the gradient elution fraction-collecting method of Moore and Stein[6] employing the cation exchange resin 'Dowex 50' of 4 per cent cross-linking was used Under these conditions ASA emerged cleanly from the column as two separate peaks which we now know corresponded to the two anhydride forms *B* and *C* The rate of chromatographic development of these columns is slow (6–8 ml /hr) and ASA is subjected to a *p*H of between 3 and 4 for a period of about 60–70 hr at 30–50° C This time is presumably long enough for the ASA to be completely converted to the two anhydride forms which emerged from the columns in the position on the flow sheet between the peaks of leucine and tyrosine

More recently we have attempted to measure ASA using an automatic self-recording amino-acid analyser[7] which has been built in this Department This method used the 'Amberlite' cation-exchange resin *CG*–120 of 8 per cent cross-linking and the columns are operated at a flow-rate of 30 ml /hr ASA is not eluted from the 150 cm column with the *p*H 3 25 buffer at 30°, but after changing to the *p*H 4 25 buffer at 55° a small amount of free ASA emerges after the passage of the new buffer front and this is followed by a slowly rising baseline and the emergence of several partially separated peaks immediately after the phenylalanine position Pure samples of either of the *B* and *C* anhydrides when treated similarly are stable and give each time a single peak at 5 and 45 ml , respectively, after the centre of the phenylalanine peak There is no sign of any reconversion to ASA and the baseline is unaltered We believe, therefore, that after only 10 hr at 30° with the *p*H 3 25 buffer the original ASA is not fully converted to the anhydride forms; conditions are then changed to *p*H 4 25 at 55°, but before a new equilibrium is attained a mixture of ASA and its anhydrides is eluted from the column

On the 50 cm column used for the estimation of basic amino-acids in biological fluids, operated at *p*H 4 19 and 30°, free ASA emerges at 25 ml and the anhydrides *B* and *C* at 50 and 60 ml respectively About 5 per cent of anhydride was found in the analysis of a sample of ASA on the 50 cm column, but this amount could well have been present in the original sample itself It is therefore possible to estimate ASA in pure solution on the 50 cm column but this is of little practical use since the presence of the acidic and neutral amino-acids, which are usually present in biological fluids, grossly interfere at the beginning of the run between 10 and 40 ml

In order to overcome these difficulties we have made use of the fact that ASA in solution can be readily converted to the anhydride forms by standing for 48 hr at *p*H 2 and the anhydrides are stable providing the *p*H does not rise above 5 Provided that the cyclization is complete then the formed anhydrides can be determined on the 50 cm column where they emerge conveniently between the large peak of combined acidic and neutral amino-acids and the peak given by phenylalanine and tyrosine at about 80 ml In a test of the experimental conditions by analysis carried out on the 50 cm column, 1 μmole of a sample of ASA gave, after standing at *p*H 2 for 24 hr at 20°, 0 04 μmole of ASA, 0 04 μmole of *B* and 0·69 μmole of *C* After increasing the time of standing to 48 hr the values were 0 01 μmole of ASA, 0 04 μmole of *B* and 0 71 μmole of *C*

Provisionally we are applying a correction factor to compensate for the 75 per cent recovery of ASA as the anhydrides

In practice, samples of urine and deproteinized plasma are brought to *p*H 2 by the dropwise addition of 2 *N* hydrochloric acid and are allowed to stand at room temperature for 48 hr prior to analysis.

Miles Laboratories Inc and the Ames Co , Ltd , provided a generous grant for the construction of the automatic amino-acid analyser which was built in the Medical Unit by Mr C. E Glover and Mr. G Marshall

One of us (D C C) is indebted to the Drummond Trust for a senior fellowship

Chromatographical Separation of Carbohydrate O-Isopropylidene Derivatives

DURING investigations on fluorocarbohydrates, it became necessary to examine the purity of small amounts of *O*-isopropylidene derivatives Hitherto, for such compounds in the carbohydrate series, there has been no reliable chromatographical method of separation from fully protected or nearly related hydroxylated compounds We have found, however, that separations can be achieved rapidly and easily by reversed-phase, ascending chromatography on cellulose acetate strips (20 × 4 5 cm , as used for electrophoresis and obtainable from Oxo, Ltd , Queen Street Place, London, E C 4)

Strips were washed thoroughly in methanol and dried in air Compounds (50–800 μgm in ethanol) were applied as spots to the washed strip which were then developed by ascending chromatography with a mixture of methanol and water (6/4 v/v). The separation was achieved in 2 hr at 2–5° C

After drying for 20–25 min in air at room temperature, compounds can be detected in two ways

(*a*) Developed chromatograms are immersed in a solution[1] of 2,4-dinitrophenylhydrazine (0 4 per cent w/v) in 2 *N* hydrochloric acid Carbonyl, *O*-isopropylidene and *O*-benzylidene compounds appear as deep yellow zones which are further intensified when the chromatogram is washed briefly in aqueous sodium hydroxide (10 per cent w/v)

(*b*) Alternatively, the developed chromatograms are floated on the surface of a solution[2] (1 per cent w/v) of potassium permanganate in 1 *N* sulphuric acid for 2 min and immersed for a further minute The chromatogram is then washed in running water, when the components appear as sharply defined purple-brown spots, which turn brown on standing This is sensitive to about 150 μgm of such compounds as 1,2 5,6-di-*O*-isopropylidene-D-glucose

Table 1

Substance	*R_F*	No. of free hydroxyl groups
1,2 4,5-di-*O*-isopropylidene-3-mesyl-D-fructose	0 15	0
1,2-*O*-benzylideneglycerol	0 23	1
Methyl *O*-isopropylidene-DL-glycerate	0 28	0
1,2 3,4-di-*O*-isopropylidene-6-tosyl-D-galactose	0 32	0
Methyl 2,3-*O*-isopropylidene-αβ-D-ribofuranoside	0 48	1
1,2 5,6-di-*O*-isopropylidene-D-glucose	0 52	1
1,2 3,4-di-*O*-isopropylidene-D-galactose	0 55	1
1,2-*O*-isopropylideneglycerol	0 65	1
Methyl DL-glycerate	0 66	2
(±)-butan-1,3-diol	0 73	2
1,2-*O*-isopropylidene-D-glucofuranose	0 80	3
2,3,4,6-tetra-*O*-methyl-D-glucose	0 90	1
Methyl 2,3,6-tri-*O*-methyl-αβ-D-glucoside	0 98	2
3-*O*-methyl-D-glucose	0 98	4

As seen from the list of R_F values in Table 1, the method in general can be used to distinguish fully protected sugars from those with one or more free hydroxyl groups In general, unsubstituted sugars move at the solvent front

Isolation of Histones(?) from *Staphylococcus aureus*

ANY theories that try to give an explanation of the function of histones have had in the past to take account of the reported absence of histones from bacteria[1,2] If histones are solely concerned with cell differentiation or 'gene suppression' in multicellular organisms, then one might expect them to be absent from bacteria and protozoa[3,4] But if, on the other hand, they have an even more fundamental function, related to the function of deoxyribonucleic acid (DNA) in all cells, then they should also be present in unicellular organisms

In the present investigation an attempt was made to extract basic proteins from bacteria, following a modification of the procedure routinely used in our laboratory for the isolation of histones from cell nuclei[5]

The bacteria, *Staphylococcus aureus*, were washed with 4 per cent acetic acid, and then defatted and dried by washing several times with ethanol and then with ether This procedure denatures many of the non-basic proteins, rendering them insoluble on extraction with acid The acid-soluble proteins were extracted by grinding the dried bacteria with glass powder in the presence of 0 1 *N* sulphuric acid, and then centrifuging Large amounts of non-protein material extracted were removed by dialysis against 0 1 *N* sulphuric acid, and the proteins were precipitated from the dialysed extract by the addition of seven volumes of ethanol, and dried with ethanol followed by ether

Some of the extracted material was subjected to starch-gel electrophoresis in the presence of 4 *M* urea

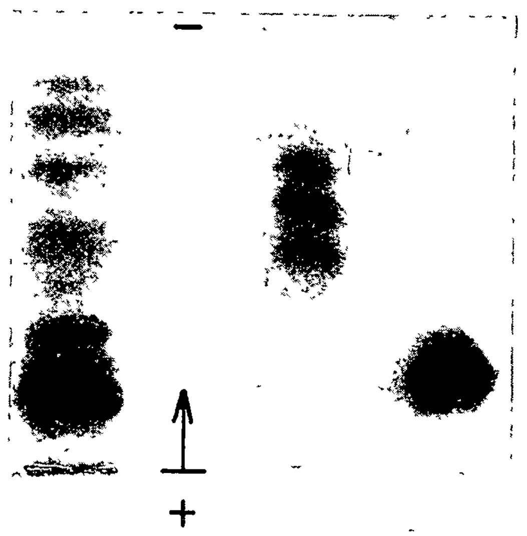

Fig 1 Starch-gel electrophoresis of proteins extracted from *Staphylococcus aureus* with 0 1 *N* sulphuric acid (*a*) total protein, (*b*) basic protein fraction, (*c*) non-basic fraction

using a modification of the technique developed by Neelin and Neelin for use with histones[6] The gel, rolled 1 mm thick on a glass plate and coated afterwards with paraffin wax, was prepared with 0 014 *M* acetate buffer containing the urea, giving a *p*H within the gel of 6 After migration, the gel was stained with amido black 10*B* and showed the presence of at least eight components (Fig. 1). The direction of migration of the slower components is reversed if the *p*H of the gel is increased above 6 5

Those components which were strongly basic, like histones, with isoelectric points well above *p*H 7 were separated from the others by using carboxymethyl-cellulose The protein mixture, dissolved in bicarbonate buffer *p*H 7, was applied to a very short carboxymethyl-cellulose column previously washed with buffer Under these conditions the non-basic components run through the column while the more basic components are retained The column was washed with water, and then the basic proteins eluted with about 1 ml of 0 1 *N* hydrochloric acid

Starch-gel electrophoresis of these two fractions, recovered from the eluates by ethanol precipitation, shows the complete separation of the faster components from the remainder, which, although extracted by acid, do not have isoelectric points above *p*H 7 (Fig 1)

Amino-acid analysis of both fractions, by acid hydrolysis followed by paper chromatography (two successive runs in one direction using an *n*-butanol, acetic acid, water system and detection of the spots by ninhydrin reagent), indicated that the faster, more basic fraction was very similar to unfractionated ox-thymus histone[7] It contained particularly large amounts of lysine, arginine, alanine, leucine and proline with relatively small quantities of acidic amino-acids, histidine and tyrosine, while the slower, less basic fraction was quite different It is concluded from the above results, from ultra-violet absorption and from solubility characteristics that the proteins in the faster electrophoretic fraction are very similar indeed to histones

Thus it is clear that these bacteria contain basic proteins like the histones found in the higher forms of life Comparable results have been obtained with *Micrococcus lysodeikticus* These basic proteins may also occur in the DNA-protein fraction previously isolated by Vendrely *et al* from *Escherichia coli*[8].

It is not yet possible to say whether all the basic protein components demonstrated here have come from association with the DNA or the ribonucleic acid of the bacteria But somewhat similar components have recently been shown to occur in ribosomes prepared from *Escherichia coli*[9].

We wish to thank Dr J F Wilkinson for providing us with liberal supplies of bacteria

Detection and Distribution of Enzymes for oxidizing Thiocysteamine

The intermediate role of the persulphide analogues (R—SSH) of cysteine and cysteamine in the biological conversion of cystine and cystamine into the corresponding sulphinates and thiosulphonates has been suggested in ref 1. This view has been emphasized by the detection of an enzyme, or enzyme system, able to convert thiocysteamine (the persulphide analogue of cysteamine NH_2—CH_2—CH_2—SSH) into thiotaurine (R—SO_2SH) and hypotaurine (R—SO_2H) in the presence of air[2] Careful study of this reaction merits attention since it may throw light on the first steps of the metabolic pathway of cystine and cystamine.

In our earlier work[2] thiotaurine and hypotaurine were detected in the incubation mixtures by using labelled substrate and by submitting the final deproteinizate to chromato-radioautography or chromato-scanning. Although providing good results, these methods are time-consuming, expensive, and cannot be used as routine procedures for the isolation of the enzyme. Thus we have sought simpler methods for obtaining activity values Since thiotaurine is the main product of the enzymic oxidation of thiocysteamine, methods have been tried for determining this compound. The cyanolysis method[3] and ion-exchange chromatography[4,5] seemed simple enough and were adapted to the determination of thiotaurine in our incubates The results obtained with these two methods have been compared with those obtained by scanning radiochromatograms

The enzyme was extracted from pig kidney by fractionation between 20 and 60 per cent ammonium sulphate[2] Thiocysteamine was produced in the incubates by adding cysteamine hydrochloride and elementary sulphur[2]. The experimental conditions are reported in Tables 1 and 2 The distribution of the enzyme has been investigated by comparing the amount of thiotaurine produced under standard con-

Table 1. TIME-COURSE OF THE ENZYMIC CONVERSION OF THIOCYSTEAMINE INTO THIOTAURINE, AS DETERMINED BY THREE DIFFERENT METHODS

Enzyme: 32 mgm. of proteins of 20–60 per cent ammonium sulphate saturation fraction of pig kidney homogenate dissolved in 2 ml. water. Thiocysteamine: 50 μmoles containing 8 μc. of sulphur-35. Phosphate buffer pH 7·4: 0·6 ml., 0·1 M. Final volume, 3 ml.; Temperature, 38°. Values reported in μmoles of thiotaurine produced

Time of incubation (hr.)	Cyanolysis	Ion-exchange chromatography	Chromato-radio scanning
2	2·3	1·9	2·3
4	2·5	2·1	2·8
6	2·9	3·3	3·0

Table 2. DISTRIBUTION OF THIOCYSTEAMINE OXIDIZING ENYZME

Values in μmoles of thiotaurine produced after 2 hr. under standard conditions by using the cyanolysis procedure. Conditions were the same as described in Table 1, with the exception that the enzyme was substituted with 2 ml. of a homogenate of 1 part of the organ with 5 parts of phosphate buffer, and that thiocysteamine was not labelled

	Kidney	Liver	Muscle	Heart
Rat	1·35	1·72	0·91	0·85
Rabbit	1·23	0·50	0·23	0·25
Pig	1·76	2·56	—	0·48
Cattle	2·07	0·90	0·50	0·88
Horse	4·88	1·21	0·71	0·90

ditions by the same amount of homogenate of various organs. Details are reported in ref. 2.

The cyanolysis technique was that described by Sorbo[3]. Various controls have been performed and it was found that interfering substances were removed by the addition of 'Dowex 50'. The cyanolysis determination was performed as follows. The final incubation mixture (3 ml.) was deproteinized with 0·3 ml. 100 per cent trichloracetic acid and added to 0·3 gm. of 'Dowex 50 ×4', 200–400 mesh, in the H$^+$ form. After shaking and centrifuging, an aliquot of the supernatant was added with 2 ml. 1 N ammonia and 1·5 ml. of 0·1 M potassium cyanide. After 30 min. in a boiling water-bath, the solution was cooled, added to 1 ml. ferric nitrate reagent[3] and read at 470 mμ.

Ion-exchange determination of thiotaurine was performed on the trichloracetic filtrate, without the addition of the resin, following the procedure of Stein[5]. The eluant was 0·1 M citric acid in 0·2 M sodium chloride at 37°. By using this solution, thiotaurine is eluted together with taurine, far from other disturbing amino-acids[4]. Since our enzyme preparation was free from taurine, the peak which developed with ninhydrin in the area of thiotaurine was calculated as pure thiotaurine.

The procedure for scanning uni-dimensional radiochromatograms has been described in ref. 2. We have observed that part of the radioactivity is recovered in the trichloracetic precipitate at the end of the incubation. This is probably due to exchange of thiocysteamine with thiols and disulphides of proteins[6]. For that reason values for thiotaurine have been calculated by comparing the radioactivity of the area occupied by thiotaurine in the chromatograms with the radioactivity of a known amount of the substrate. In our earlier papers radioactivity of thiotaurine was compared with the radioactivity distributed in the whole chromatogram. The yield of thiotaurine, by using the present procedure, is consequently lower than that reported in ref. 2 and is more accurate.

As shown in Table 1, the procedure for cyanolysis gives results which are comparable with those obtained by ion-exchange and by chromato-radioscanning. This finding permits the use of the very simple procedure of cyanolysis for the detection of the enzyme. Table 2 shows the first results of the study of the distribution of the enzyme in various organs and animals. These preliminary results suggest a wide distribution of the enzyme and a general importance of the reaction. Moreover, they indicate that the horse kidney is the best source for the extraction of the enzyme.

This work has been aided by a grant of the Consiglio Nazionale delle Ricerche.

Presence of Haptoglobin in Synovial Fluid

ELECTROPHORETICALLY classified α- and β-glycoproteins have been shown to be normal constituents of synovial fluid[1]. Evidence based on immunoelectrophoresis and Cohn fractionation of human traumatic effusions also suggests the presence of most of the serum proteins in synovial fluid[2,3]. Individual biologically active serum proteins have also been found, namely, some enzymes[4], siderophilin[3], cærulo-plasmin[3], and the thyroxine-binding protein[5]. The accepted blood-coagulating factors, however, were found to be absent from normal bovine fluid[6].

In an experiment using starch-gel electrophoresis, the patterns obtained with bovine serum and synovial fluid were found to be identical. Electrophoretic zones obtained for both were albumin, α-globulin, 4β-globulins, a slow α-globulin and γ-globulin[7]. Since the hæmoglobin-binding protein, haptoglobin, migrates electrophoretically as an α-globulin, it seemed likely that this glycoprotein might be a normal constituent of bovine synovial fluid. Its presence in the normal fluid was further suggested by its relatively low molecular weight (85,000).

Since haptoglobin complexes hæmoglobin[8], its presence is readily ascertained by determining the electrophoretic migration of the haptoglobin–hæmoglobin complex. Thus, at a pH of 7·0–7·5 the complex migrates anodically while free hæmoglobin is immobile. The amount of haptoglobin may then be expressed in terms of the hæmoglobin-binding capacity.

In the present work the electrophoretic procedure was that described in detail by Zak *et al.*[9] using a dilute agar medium. A 0·25 per cent solution of agar (certified pure) in 0·05μ veronal–citrate buffer of pH 7·3 (10·3 gm. sodium barbital and 2·1 gm. citric acid per litre) was transferred to an 8·3 cm. × 10·2 cm. glass basin containing a sheet of parchment paper (No. 72 vegetable parchment powder paper, Upjohn Co.). After electrophoresis for 45–50 min. at 250 V. and 40–60 m.amp., the agar plate was dried under an infra-red lamp. The dried parchment paper was stained with a 1 : 1 mixture of benzidine (saturated solution in glacial acetic acid) and hydrogen peroxide (3 per cent solution). The hæmoglobin-containing bands gave a typical blue reaction.

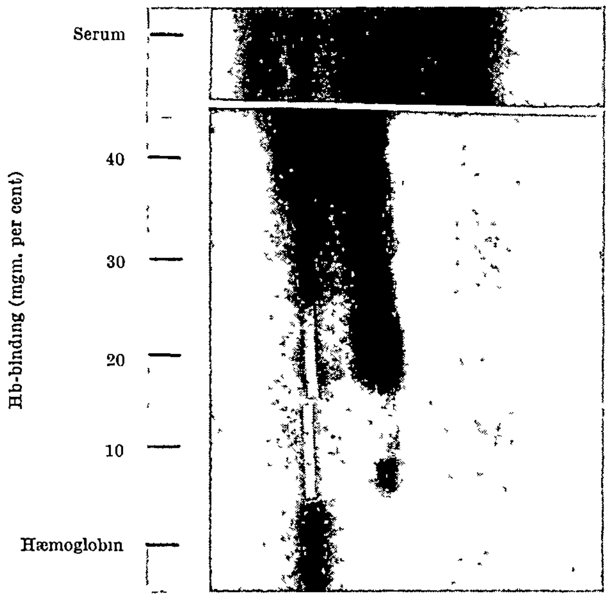

Fig. 1. Electrophoretic determination of hæmoglobin-binding capacity in human serum

Graded series of bovine sera and concentrated synovial fluids were prepared so as to contain 5, 10, 20, 30 and 40 mgm. per cent of hæmoglobin. For these a standard solution (5 gm. per cent) was previously diluted to contain 50, 100, 200, 300 and 400 mgm. per cent. Then 0·01 ml. aliquots of the diluted standard solutions were mixed with 0·1 ml. portions of serum or concentrated (1 : 10) synovial fluid. Bovine synovial fluids (5 ml.) were first incubated with hyaluronidase prior to concentration by lyophilization. Small strips (0·5 mm. × 8 mm.) of Whatman No. 3 *MM* filter paper were soaked in the samples and then were placed on the agar gel approximately 1·5 in. from the cathodic end.

In a preliminary experiment, human serum was used (Fig. 1) to establish the applicability of this electrophoretic technique to the determination of haptoglobin. Fig. 2 demonstrates the presence of haptoglobin in bovine synovial fluid. Free hæmoglobin remained at the origin while the haptoglobin-bound hæmoglobin migrated between the α- and β-fractions. The average hæmoglobin-binding capacity of seven samples of concentrated synovial fluid was approximately 10 mgm. per cent. When based on the total protein content of synovial fluid (average 1 gm. per cent) the binding-capacity was 1 mgm. of hæmoglobin per gm. of total protein. Bovine serum gave a range of 10–20 mgm. per cent. However, it was impossible to collect bovine serum from the slaughter-house without some degree of hæmolysis. Determinations of the content of hæmoglobin showed the presence of 5–10 mgm. per cent in the serum. Therefore, the actual hæmoglobin-binding capacity for serum averaged 20 mgm. per cent for 7 animals or 2·5 mgm. of hæmoglobin per gm. of total protein.

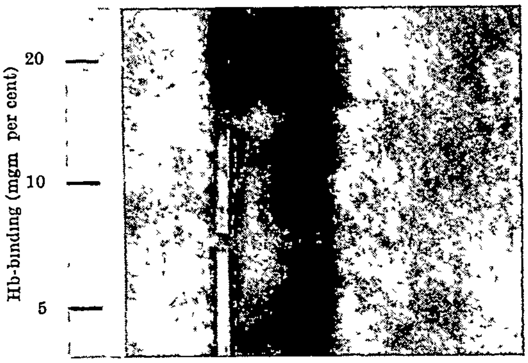

Fig. 2. Electrophoretic demonstration of haptoglobin in normal bovine synovial fluid

On the basis of the preceding results, it is apparent that the glycoprotein, haptoglobin, is a normal constituent of bovine synovial fluid. The hæmoglobin-binding capacity of synovial fluid, expressed in mgm. hæmoglobin/gm. total protein, is approximately 40 per cent of the binding capacity of the serum.

PHYSIOLOGY

Hormonal Control of Oxidized Flavour in Milk

IN two recent papers the importance of natural copper in producing oxidized flavour in milk has been stressed[1,2]. The pronounced effect of adding copper salts to induce oxidized flavour, as well as the inhibiting effect of a great many compounds with copper-binding abilities, has been recognized for a long time. Contamination with copper occurs easily in metal equipment with which the milk has been in intimate contact[3]. Contribution from equipment was considered to be the main origin of copper in milk, and thus the importance of natural copper for development of oxidized flavour may have been overlooked. High copper values are found in carefully sampled milk[1,4], and particularly high values in milk from the early lactation period[1]. Elevated content of natural copper in this period seems to indicate a hormonal regulation of copper metabolism. The copper-catalysed oxidation in milk may be enhanced or depressed, and factors of this kind will combine to give the final result. The addition of copper sulphate to milk is a method used to evaluate these factors, or the so-called susceptibility, and is of practical importance. The relative effect of natural copper contents is lessened. Indications of hormonal influence on oxidized flavour in milk are reported here.

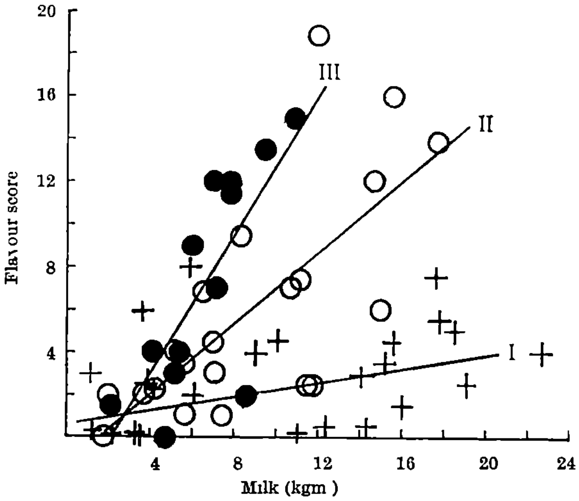

Fig. 1. Flavour score versus milk yield. Groups I, II and III are cows with 4 or more, 2 and 3, and 1 gestations, respectively. Coefficients of correlation are 0·34, 0·70 and 0·74. Scores of group I are significantly lower than those of groups II and III

The results are obtained by scoring milk from the College farm herd, sampled from each cow during milking. The samples were left overnight in the cold store to be judged next day by a single taster. Oxidized flavour scores were magnified by adding copper sulphate to the milk samples. Thus, sufficient grading was attained, and this made statistical treatment possible. Good correlations were obtained for flavour score versus milk yield on the same day, especially when the cows of the herd were divided into groups due to the number of gestations they had had. The interrelations given in Fig. 1 for a scoring in September are retained for all parts of the year and lactation period. Very recent freshened cows may, however, disturb the regression, particularly cows in their first lactation period. The regression coefficient in the latter case has a negative value in the first part of the lactation period.

The liability of a certain farm to produce milk with oxidized flavour must then, besides frequency of recent calvings, also depend on age-distribution of the animals. The correlation coefficient between the sum of monthly flavour scorings of untreated milk last year and the average age of animals in 23 herds in the district was found to be − 0·52, with regression coefficient significantly deviating from zero. Milk sampled from farms was drawn at point of delivery.

When a group of young cows was followed through a 5-wk period, 8 cows showed heat. The average score throughout the 3-wk sex cycle could then be calculated and plotted. The curve showed its summit at, or near, the day of heat (Fig. 2).

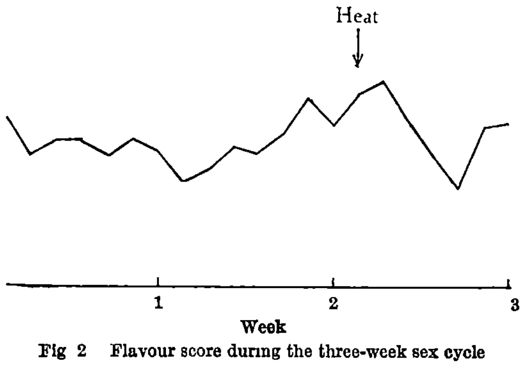

Fig. 2. Flavour score during the three-week sex cycle

Not only natural copper but also pro- and antioxidants may contribute to the noted differentiation in Fig. 1 so far as they are controlled by the same mechanism.

Physical state, like size of fat globules, organizing and complexing compounds (important for excretion of copper in milk), or tocopherols, are factors likely to interfere with oxidation and may be factors influenced by hormonal activity.

Thyroid Activity at Higher Ambient Temperatures

THYROID activity is increased in animals exposed to cold with release of thyroid hormone[1] and both the output from, and the uptake of, iodine-131 by the thyroid is augmented[2,3], but the blood-level of protein-bound iodine[4] and the epinephrine-potentiating effect of thyroxine[5] are decreased. Work on the evolution of thermoregulation reveals that birds and baby mammals suffer from defective thermoregulation[6,7] and there is increased activity of the adrenergic system on exposure to high ambient temperature[8,9]. In the present investigations, thyroidal activity of birds and baby rabbits has been investigated after exposing them to high ambient temperature.

Baby rabbits (weighing about 300 gm.) and pigeons (weighing about 275 gm.), maintained at an average temperature of 32° C., served as controls, and they were exposed to 45° C. and 48° C. respectively in constant-temperature chambers for 2·5 hr., the standard error of temperature variation being within ± 0·03° C. Protein-bound iodine (PBI) level of serum was estimated[10] and a histological study of the thyroid was carried out. After exposure to heat, the PBI-level increased in blood in both groups. Histological work on the thyroid showed an increase in acinar cell height (140 per cent) with an overall release of the acinar colloid in pigeons exposed to heat, while in the exposed baby rabbits there is no significant increase in acinar cell height, although there is a slight release of the colloid (Table 1).

On exposure to cold there is an excessive release of thyroid hormone, but the serum PBI-level falls due to greater utilization of the hormone in the cold[11,12]. In the present work, the high concentration of serum PBI, associated with histological evidence of release of thyroid hormone, might indicate a decrease in peripheral utilization of the latter, although this point has not yet been verified experimentally. Thyroid acinar cell height in pigeons exposed to heat is 140 per cent of the control, while in the baby rabbits there is no difference, indicating increased thyrotrophic hormone secretion by the anterior pituitary in pigeons, probably as a result of the stimulation of hypothalamus. In the baby rabbits a small depletion of thyroid colloid with unaffected acinar cell height indicates little release of thyrotrophic hormone. This difference in behaviour might be due to the fact

Table 1 NORMAL PIGEONS AND BABY RABBITS EXPOSED TO WARM ENVIRONMENT

Animals, with number in parentheses		Ambient temperature	Serum PBI in μgm per 100 ml ± standard deviation	Increase (per cent)	Thyroid acinar cell height in μ ± standard deviation	Increase (per cent)	Colloid
Pigeon	(15)	32° C	4 37 ± 1 02	143	3 31 ± 0 42	140	Overall release
Pigeon	(15)	48° C	6 23 ± 0 90		4 62 ± 0 63		
Rabbit	(12)	32° C	6 32 ± 1 1	24	4 40 ± 0 60	101*	Release, but comparatively less
Rabbit	(12)	45° C	7 84 ± 1 0		4 46 ± 0 51		

* Not statistically significant.

that these baby rabbits have passed the stenothermic phase of thermoregulation and the small release of thyroid hormone is probably a direct temperature effect unlike that in pigeons[9] The cause of the increased serum PBI concentration and its physiological effect on tissue respiration are being investigated

Effect of Quinones on the Uptake of Oxygen by Red Cells

IT is well recognized that many oxidizing agents will convert hæmoglobin to methæmoglobin Among these are the quinones[1] Vitamin K_3, however, could have an additional effect through its role in electron transport[2], although it is difficult to envisage a complete electron chain since mature red cells possess no cytochromes

In this work human erythrocytes were separated from plasma and the other formed blood elements and incubated in a Warburg manometric apparatus in the usual way[3]. Vitamin K_3 (0 2 mgm /flask), 1 4-naphthoquinone (0 2 mgm /flask), which has a similar structure but no known physiological role, and dicoumarol (0 3 mgm /flask), an analogue of vitamin K_3 and also a potent inhibitor of vitamin K_3 reductase[2], were added from the side-arm at the beginning of the experiment as indicated

Red cells have a predominantly glycolytic metabolism The small amount of oxygen uptake (Fig 1) is probably accounted for by the auto-oxidation of hæmoglobin to methæmoglobin Normally the latter so formed is reduced by reduced diphosphopyridine nucleotide (DPNH) derived from the oxidation of 3-phosphoglyceraldehyde, the reaction being catalysed by methæmoglobin reductase As a result of this reduction mechanism only 1–2 per cent of the total hæmoglobin is normally present as methæmoglobin. Following the addition of vitamin K_3 or 1 4-naphthoquinone there was a rapid oxidation of hæmoglobin to methæmoglobin within 2 min and a corresponding oxygen uptake Thereafter the rate of oxygen utilization fell but was still greater than in the absence of the quinones. After 3 hr incubation 45 per cent of the hæmoglobin was present as methæmoglobin compared with 1·7 per cent in the absence of quinones Dicoumarol has no effect on oxygen uptake nor does it lead to the formation of methæmoglobin

In the absence of glucose the rate of uptake of oxygen fell after 1 hr and the level of methæmoglobin in the presence of vitamin K_3 or 1 : 4-naphthoquinone was 58 per cent after 3 hr This may be attributed to the gradual depletion of endogenous glucose, which makes available a supply of DPNH and TPNH for methæmoglobin reduction Similar results were obtained using lysed red cells Under these conditions uptake of oxygen is much reduced, possibly due to configurational changes in the proteins or co-factor dilution

Elsewhere[3] we have shown that compounds which lead to the production of methæmoglobin in the cell stimulate both uptake of oxygen and the amount of glucose oxidized via the pentose pathway with the production of TPNH, which then reduces methæmoglobin There is at present some controversy as to whether DPNH and TPNH are linked to the same or different enzymes

Since vitamin K_3 and 1 4-naphthoquinone had identical effects on oxygen uptake and led to the formation of excess methæmoglobin in the cells while dicoumarol did not depress oxygen uptake, it would

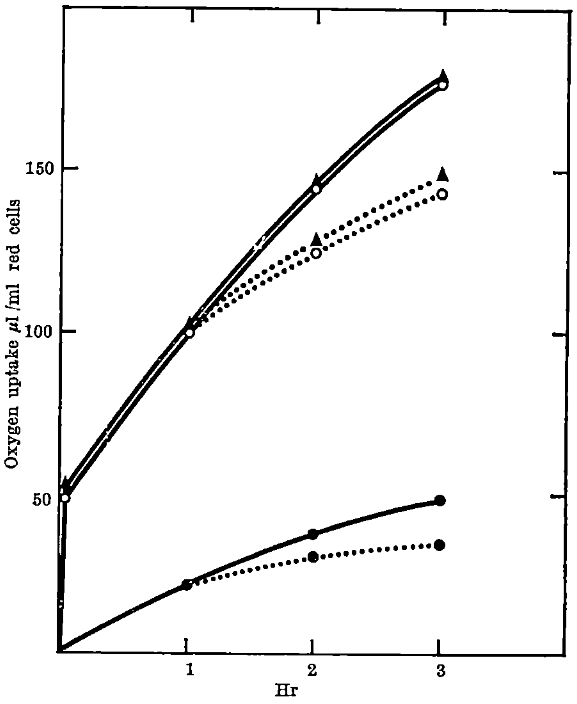

Fig 1 Effect of quinones in presence and absence of glucose on oxygen uptake of 1 ml of packed red cells in isotonic buffer *p*H 7 4 at 37°
●—●, red cells + glucose only , ● · ●, red cells without glucose added , ○—○, red cells + 1 4-naphthoquinone + glucose , ○ · ○, red cells + 1 4-naphthoquinone without glucose added , ▲—▲, red cells + vitamin K_3 + glucose , ▲ ▲, red cells + vitamin K_3 without glucose added

seem that the effect of vitamin K_3 in stimulating oxygen uptake by the red cells is a result of the oxidation of hæmoglobin.

Plasma Albumin Catabolism in Experimental Nephrosis

GLOMERULAR filtration and tubular re-absorption of plasma albumin occur as part of the normal function of the mammalian kidney[1] The fate of the re-absorbed protein is less certain Oliver *et al* [2] have presented evidence that enzyme systems capable of catabolizing certain of the plasma proteins exist in the renal tubule cell, suggesting that re-absorbed protein is broken down in transit through the cell However, we have demonstrated that in the normal rat[3] and dog[4], bilateral nephrectomy depresses the breakdown of plasma albumin to only a limited extent The amount of plasma albumin contained in the renal tubules of rats with experimental nephrosis is much greater than normal, and Goodman and Baxter[5] maintain that this is due to enhanced glomerular filtration and subsequent tubular re-absorption of greater than normal quantities of plasma protein. We have reasoned that if the kidney has any important role in plasma albumin catabolism it should be demonstrable under these conditions of exaggerated albumin reabsorption

Rats were made nephrotic by 5–10 daily subcutaneous injections of the aminonucleoside of puromycin[6]. Such rats had plasma albumin concentrations of 8–15 mgm /ml., and they excreted 100–250 mgm of albumin daily in their urine With 8–10 injections most rats had lipæmic sera, œdema, and ascites With 5–7 injections the serum was often clear, there was less œdema, and only occasional ascites. Animals were used within 15 days of the start of injections Rat plasma albumin was iodinated with iodine monochloride labelled with iodine-131 (ref 7) and 'screened', according to McFarlane[8], for 2–4 days before use All rats received 0 3–0 8 μc. of screened iodoalbumin intravenously immediately after nephrectomy or sham nephrectomy Urine was collected quantitatively when available After 8 or 24 hr rats were killed and ground in a meat grinder, and the non-protein radioactivity extracted from the ground rat tissue with trichloroacetic acid The methods used have been described previously[3]

The results are summarized in Table 1 Normal rats broke down 24 per cent of the injected iodo-albumin in 24 hr Following nephrectomy the rate of breakdown in the non-nephrotic rats averaged 20 per cent This is a significant change, and carries a P value of 0 01–0 005 In previous experiments with screened iodo-albumin[3] we found depression in breakdown following nephrectomy of 0–15 per cent, and experiments with perfused kidney[3] indicated that up to 15 per cent of the albumin turnover in the body may occur in kidneys.

Table 1 EFFECT OF BILATERAL NEPHRECTOMY ON IODOALBUMIN BREAKDOWN IN NORMAL AND NEPHROTIC RATS

Duration of exp (hr.)	Condition of animal	Bilateral nephrectomy	No of rats	Iodoalbumin breakdown Injected radioactivity (per cent) Range	Average
24	Nephrotic	–	22	16–29	23
		+	21	4–15	11
24	Normal	–	16	20–28	24
		+	12	16–26	20
8	Nephrotic	–	13	8–15	12 5
		+	13	2 5–9 0	4 6

Nephrotic rats broke down 23 per cent of the injected iodoalbumin in 24 hr and about 14 per cent in 8 hr On removal of the kidneys breakdown was markedly reduced, averaging 11 and 5 per cent in 24 and 8 hr respectively In nephrotic rats the turnover of plasma albumin is very rapid (estimated half-life 4–12 hr) This is due primarily to the urinary excretion of albumin, which in a day amounts to several times that of the circulating plasma albumin 30–80 per cent of the injected radioactive iodoalbumin was excreted as such in the urine within 24 hr

It should be stressed that the breakdown of radioactive iodoalbumin recorded in Table 1 cannot be directly equated with the rates of breakdown of the total exchangeable plasma albumin In rats without proteinuria the breakdown of iodoalbumin reflects primarily the catabolism of plasma albumin, and during the period of these experiments iodoalbumin breakdown is approximately proportional to the rate of albumin catabolism On the other hand, in animals with extensive proteinuria, labelled iodoalbumin is removed very rapidly from the circulation and the specific activity of circulating albumin drops to within 10–20 per cent of the initial value within 24 hr. In the experiments described here, the nephrotic rats retained from less than 20 to 50 per cent of the injected radioactivity in the exchangeable albumin pool On the other hand, in animals without proteinuria (including nephrectomized nephrotics) 70–80 per cent of the injected radioactivity was retained. Thus the effect of removal of kidney on the rate of plasma albumin breakdown in the nephrotic rat cannot be readily estimated in quantitative terms from our results. To evaluate quantitatively the effect of nephrectomy on the rate of albumin breakdown the turnover kinetics of albumin in animals with and without kidneys must be evaluated For this purpose the size of the vascular and extravascular albumin pool, the rates of albumin excretion, breakdown, and synthesis, as well as the rates of exchange of albumin between the vascular and extravascular pools must be determined Most of these parameters are being measured in work now in progress in our laboratory

In spite of the limitations indicated above, our results indicate that albumin catabolism is greatly reduced following nephrectomy in nephrotic rats In these animals the initial fractional rate of iodoalbumin degradation, and thus of plasma albumin breakdown, is as high as in normal rats On nephrectomy the initial fractional breakdown of iodoalbumin is less in the nephrotic rat than in the normal (with or without kidneys) and much less than in the nephrotic with kidneys. This indicates that the rate of albumin catabolism in nephrotic rats without kidneys is much less than in all the other groups

It stands to reason that if the only change following nephrectomy were the elimination of albumin loss in the urine, the fractional rate of iodoalbumin breakdown should increase. This would be so, since the radioactivity of the circulating albumin pools remains high, and thus the specific activity of the breakdown products would be, on the contrary, higher than in rats the iodoalbumin of which is rapidly depleted by proteinuria. Our results show the fraction broken down is greatly decreased.

The best explanation of our findings is provided by the assumption that in the nephrotic rats, kidneys are a major site of plasma albumin breakdown. Thus, the results strongly suggest that in amino-nucleoside nephrotic rats with extensive proteinuria, removal of kidneys markedly decreases plasma albumin breakdown, and that a major, and possibly predominant, part of plasma albumin breakdown in this type of acutely nephrotic animal occurs in the kidney.

Inhibitory Properties of the Catecholamines

FOR some years considerable attention has been focused on the inhibitory action of γ-aminobutyric acid (GABA). One of the first systems used to demonstrate this property involved inhibition of the spontaneous discharge of the slowly adapting stretch receptor neurone of the crayfish[1,2]. This bio-assay procedure has been used to investigate the inhibitory characteristics of many other compounds[2–4], but none reported to date has proved more active than GABA. A number of aliphatic amino- and guanidino-acids have, however, shown activity approaching that of GABA, and pre-requisites for activity appear to be the presence in the molecule of an acidic and a suitably separated basic function. Such general characteristics are to be found among the catecholamines. The inhibitory characteristics of these substances were therefore investigated.

Pacifastacus leniusculus (Dana) was the crayfish used and the method was essentially that described by Florey[1] and by Elliott and Florey[5]. The commercially obtained compounds were made up in 'crayfish saline'[6] at *p*H 6·5–7 and the 'threshold blocking concentration' was determined; this was the concentration which would cause a transient (*c*. 20 sec.) block of the spontaneous discharge. The activity of any compound was expressed in arbitrary units, defined as the reciprocal of the concentration, in m.moles/litre, which produces a threshold block when applied to the stretch receptor neurone.

Results comparing the inhibitory activity of GABA and the catecholamines are given in Table 1. 3-Hydroxytyramine showed a much higher order of activity than GABA or the other catecholamines on every crayfish preparation used. Although there was great variability in the response of the different preparations to the substances tested, it was repeatedly shown that a given substance tested under two code numbers on a given preparation gave concordant results.

Table 1. INHIBITORY ACTIVITY OF GABA AND SOME CATECHOLAMINES ON THE CRAYFISH STRETCH RECEPTOR NEURONE

Substance	No. of preparations	Activity in units defined in text (mean)	Activity in units defined in text (range)
GABA	18	80	15–206
3-hydroxytyramine hydrogen chloride	15	6,250	566–41,580
L-noradrenaline bitartrate, water	7	110	5–468
L-adrenaline bitartrate	5	65	< 4·5–185

Our results on L-noradrenaline bitartrate and L-adrenaline bitartrate, indicating an activity comparable with that of GABA, are in conflict with those of Elliott and Florey[5], who reported that these compounds were inactive at a concentration of 1 mgm./ml. (less than 0·3 unit in each case). These workers used crayfish of the species *Orconectes virilis*, and did not specify the number of trials. The results we have obtained with many aliphatic amino- and guanidino-acids agree remarkably well with those of Edwards and Kuffler[3], who used both *O. virilis* and *Procambarus alleni*; it therefore seems unlikely that the difference in species of crayfish used can account for the difference in results between ourselves and Elliott and Florey.

The ability of various agents to block the inhibitory effects of 3-hydroxytyramine and of GABA was significantly different. Picrotoxin (10^{-3} *M*) blocked about 60 per cent of the activity of GABA, but was only slightly effective against 3-hydroxytyramine. Chlorpromazine ($1·5 \times 10^{-4}$ *M*) and dibenzylene (8×10^{-4} *M*), on the other hand, were ineffective against GABA but blocked 3-hydroxytyramine almost completely. These results suggest that more than one receptor site on the stretch receptor neurone is involved.

The significance of these results remains to be assessed by work on other systems. The high activity of 3-hydroxytyramine lends support to the many investigators who have suggested that it may be an effector substance in its own right as well as a precursor of adrenaline and noradrenaline.

Acquired Tolerance to Homografts produced by Homologous Spleen Cell Injection in Adult Mice

THE dosage of skin homografts has been shown to be a factor in their survival. While small homografts show a prolonged survival-time when compared with medium-sized grafts, the application of large or near total body size homografts results in increased survival time[1,2]. Billingham and Sparrow also showed that intravenous injection of living homologous dissociated epidermal cells caused a two- to three-fold increase in the survival of skin homografts which were afterwards placed on rabbit hosts[3]. Because of our success in producing acquired tolerance to outcross skin in adult mice using parent–F_1 hybrid parabiosis[4,5], the following experiment was designed to study the effects of dosage of homologous antigen on the future recipients of skin homografts in adults, reasoning along lines that the success of parabiosis was primarily a dosage phenomenon.

Groups of adult *C3H* female mice were injected intravenously with a spleen cell suspension obtained from either $(Ce \times C3H)F_1$ hybrid, $(A \times C3H)F_1$ hybrid, *A*, or $(C_{57}(BL) \times C3H)F_1$ hybrid mice. The contents of three donor spleens were suspended in 1 ml. of Ringer's solution such that each ml. contained 300 to 340 million nucleated cells. Injections were made intravenously through a 30-gauge needle placed in the tail vein. One week later a 2·5 × 3·5-cm. full thickness, homologous, abdominal skin-graft taken from donors corresponding to the strain of injected spleen cells was placed on the back of host animals. Each graft was rotated 180° to facilitate identification of viability and checked daily for gross signs of rejection.

Table 1 demonstrates the differences in graft behaviour between the experimental groups. $(C3H \times Ce)F_1$ hybrid skin, accepted by *C3H* hosts at 30–48 days of age, is not accepted at 120–130 days of age unless receiving spleen cells when 30–48 days old. In the case of *C3H* mice injected with $(A \times C3H)F_1$ spleen and grafted with $(A \times C3H)F_1$ skin, the final behaviour of the skin homograft depended on the dosage of spleen injected one week before grafting. Seven of ten grafts placed, following an injection of 300–340 million cells, showed no signs of destruction except in two cases where there was shrinkage to approximately 50 per cent of the original size and a less dense hair-distribution than the other 5 successful homografts (Fig. 1). These latter homografts have been viable for four and a half months. In the other 3 instances the homografts were rejected following a prolonged survival. In the strain combinations, $A \longrightarrow C3H$ and $(C_{57}(BL) \times C3H)F_1 \longrightarrow C3H$, the groups receiving intravenous spleen displayed prolonged survival of grafts but no permanent tolerance.

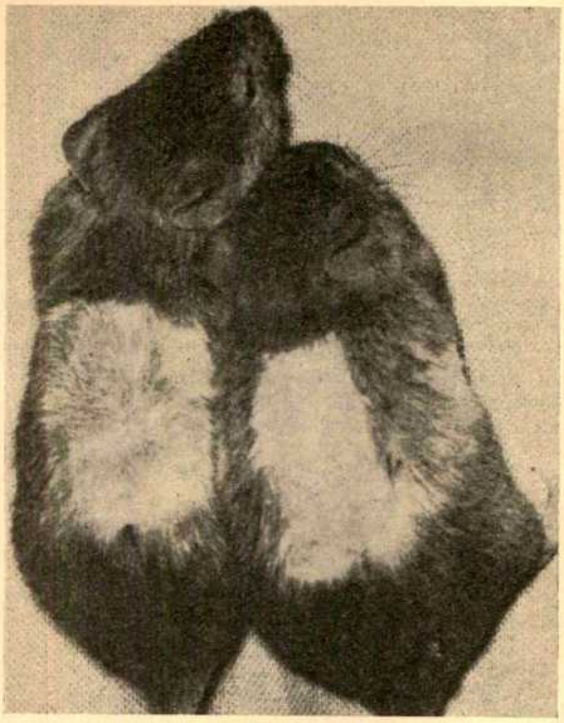

Fig. 1. *C3H* female mice bearing $(A \times C3H)F_1$ female skin-graft of 4·5 months duration. Animal on the left is one of five showing complete tolerance. Animal on the right is one of two, the graft of which is 50 per cent of the original size of grafted abdominal skin

In inbred-F_1 hybrid parabiosis of adult mice a cellular exchange between partners can result in tolerance of the inbred animal to the outcross tissue of its F_1 hybrid partner. The success in provoking a tolerant state depends on the genetic disparity between inbred and F_1 hybrid[4,5]. It would seem logical, in addition, that the dosage afforded by linking the animals is an important factor in the success of this method. The results obtained in this experiment confirm those described by Billingham and Sparrow[3] on the effect of intravenous injection of cells on graft survival. Our results indicate that high doses of homologous cells alter the subsequent capacity to react against these cells, analogous to the demonstration of immunological paralysis to pneumococcal polysaccharide by Felton[6]. The dosage effect was best demonstrated when strong histocompatibility differences were minimized by the use of hybrid

Table 1

6	*C3H* ♀	$(C_{57}(BL) \times C3H)F_1$ ♀	$3·0–3·4 \times 10^8$	$(C_{57}(BL) \times C3H)F_1$ ♀	37–55	13·6	0

* Host animals were between 30–48 days of age when injected with homologous spleen.

† Mean survival time of two rejected homografts.

‡ Mean survival time of three of ten rejected homografts.

animals. A spectrum of results was obtained depending on the genetic disparity between these hybrid to pure line grafts. $(C3H \times Ce)F_1$ skin on $C3H$ took with minimal doses of spleen in adults. The strains Ce and $C3H$ have the same H–2 locus. A large dose of spleen was required to allow the acceptance of homografts from strains differing unilaterally at the H–2 locus with $(A \times C3H)F_1$ and $C3H$. In the combinations $(C_{57}(BL) \times C3H)F_1 \longrightarrow C3H$ and $A \longrightarrow C3H$, a unilateral and bilateral H–2 locus difference respectively, even this large dose of spleen cells was insufficient to produce tolerance.

Effect of Diethylstilbœstrol on the Serum γ-Globulin in the Guinea Pig

IT has been reported previously that the active œstrogens, both natural and synthetic, are strong stimulants of the phagocytic activity of the reticulo-endothelial system[1-3]. It has also been reported that cortisone depresses reticulo-endothelial phagocytosis, lowers the total and differential white cell blood counts, and reduces the serum γ-globulin to about half the normal level[4].

The present work was carried out to ascertain whether diethylstilbœstrol, which is a strong stimulant of the reticulo-endothelial phagocytes, raises the level of γ-globulin in the serum.

Thirty-six male guinea pigs of 450–660 gm. body-weight were used in these experiments. Sixteen of the animals were used as controls of which 9 were given no treatment and 7 received 1·5 ml. arachis oil intraperitoneally daily for 6 days. The remaining 20 animals each received 0·5 mgm. diethylstilbœstrol in 1·5 ml. arachis oil intraperitoneally once daily for 6 days. The serum γ-globulin was estimated in all the animals; in the arachis oil controls and in those given diethylstilbœstrol this was carried out on the seventh day after treatment commenced.

The procedure was as follows: From each animal 2 ml. of blood was withdrawn by cardiac puncture, placed in a centrifuge tube and allowed to clot. The specimen was then centrifuged at 3,000 r.p.m. (r.c.f. 1,533*g*) for 20 min. and the supernatant serum removed by pipette. The serum proteins were then separated by paper electrophoresis, using a vertical tank, a barbitone buffer of *p*H 8·6, and Whatman filter paper No. 3 *MM*. Each separation was carried out on 0·01 ml. of serum using a current of 240 V. for 12 hr. The paper strips were dried, then stained with light green for 15 min. and excess stain removed with acetic acid until a clear background was obtained.

The relative distribution and the density of the serum protein bands were recorded using an 'Elphor' densitometer, and from the readings a graph was constructed on 1 mm. paper. The area enclosed by the curve representing the total serum protein was cut out and weighed; from this the area enclosed by the γ-globulin curve was then cut out and weighed separately.

Mean ± *S.D.*	588 ± 57·2	0·996 ± 0·071	0·191 ± 0·024

The results are shown in Table 1. It will be noted that in the untreated controls the mean weight of the graph area of total serum protein is 0·81 gm. and that of the γ-globulin is 0·069 gm. The arachis oil controls show little if any variation from the results in the untreated controls. In the animals which received treatment with diethylstilbœstrol the mean weight of the graph area of total serum protein is increased to 0·996 gm. and that of the γ-globulin to 0·191 gm. These results represent an elevation of the total serum protein-level of 23 per cent above that of the control groups. This increase is composed principally of serum γ-globulin, which in fact has risen 177 per cent above normal, whereas the remaining serum proteins as a group have increased only 9 per cent. From this evidence it appears that when the reticulo-endothelial system is stimulated by diethylstilbœstrol the serum γ-globulin is increased to about 2¾ times the normal level.

Since the development of antibodies is considered to be closely related to the serum γ-globulin, it seems likely that the great increase of the latter should be accompanied by a corresponding rise in the antibody-forming potential of the animal. This has now been confirmed by further researches which are at present being prepared for publication.

In these investigations we gratefully acknowledge financial assistance from the Tobacco Manufacturers' Standing Committee and the Medical Research Council.

HISTOLOGY

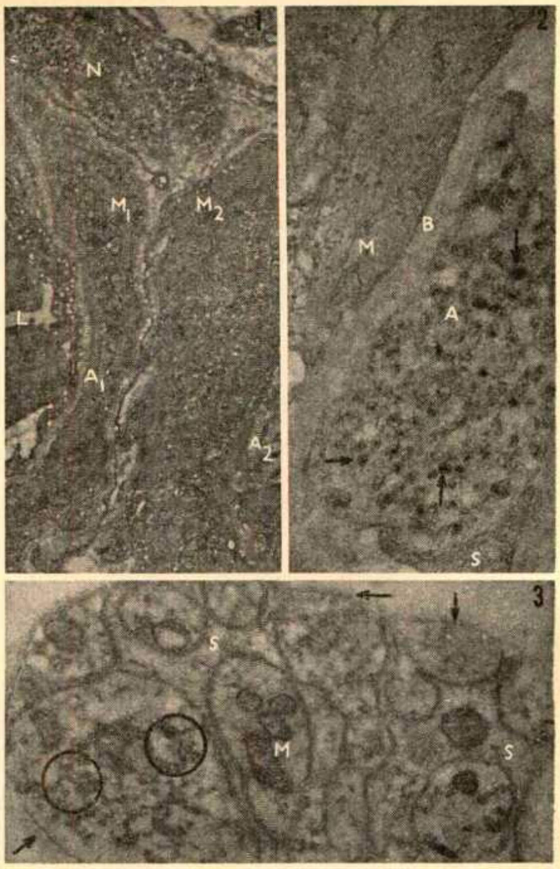
Fine Structure of the Arteriolar Nerves in the Guinea Pig Pancreas

DURING the course of an investigation into the effects of cobalt chloride on the endocrine pancreas of the guinea pig (Esterhuizen and Lever, in the press), our attention was arrested by certain fine structural features—which we believe have not hitherto been described—in the nerve fibres associated with the pancreatic arterioles.

According to Mitchell[1] the nerve supply to the pancreas is a mixture of post-ganglionic sympathetic fibres from the cœliac plexus and some vagal fibres. These nerves reach the gland by way of a peri-arterial plexus in company with the vessels of supply, and for the most part their subsequent distribution is alongside the branching arterial tree between the acini and ducts of the exocrine tissue and within the islets of Langerhans. It is likely that the pancreatic innervation is almost entirely vasomotor, although Lacy[2] has reported, and we also have seen, the occasional axon in direct contact with an endocrine cell.

One may commonly observe groups of unmyelinated axons lying together with a variable amount of connective tissue in the peri-vascular spaces around the small arteries (Fig. 1) in any part of the pancreas. At a fine structural level the well-known axon–Schwann cell relationship[3,4] can be seen in most of the nerve fibres present. That is to say, several axons are enwrapped by the plasma membrane of the same Schwann cell (Fig. 3), each being suspended by mesaxonal invaginations of this membrane. There is nevertheless a number of nerve fibres which are incompletely shrouded by Schwann plasma membrane, and, but for a thin surface covering of basement membrane, these axons could be described as naked over their exposed areas (Fig. 3).

Naked axons of this sort are seen frequently in close approximation to the muscular layer of the arterioles in the guinea pig pancreas. In electron micrographs the plasma membranes of opposing axon and smooth muscle cell are separated by a space which may either contain a single layer of a material having the appearance of basement membrane (Fig. 2), or be lined by this material both on its axonal and muscular sides. This space was found to range from 100 to 400 mμ in width. Although closer neuro-vascular approximation has not yet been observed, the high concentration of micro-vesicles and mitochondria[5] (Figs. 2 and 3) in many of the naked axons would suggest that in these situations nerve fibres are at, or near, their points of termination. Perhaps the synaptic arrangements of peri-vascular nerves are similar to those noted by Fawcett and Selby[6] at nerve endings in the turtle atrium in which contact between pre- and post-synaptic elements is not as intimate as at nerve terminals in many other situations.



Electron micrographs of specimens taken from guinea pig pancreas at intervals following intravenous injection of cobalt chloride (25 mgm./kgm. body-weight). Figs. 1 and 2, 24 hr.; Fig. 3, 2 hr. after injection

Fig. 1. Unmyelinated nerves (N) within a peri-vascular space around two small arteries A_1, A_2; lumen of first artery (L); smooth muscle cells M_1 and M_2 in walls of vessels. Note dense granular material in axons (N) (× 11,250)

Fig. 2. Naked axon (A) separated by a space containing 'basement membrane' (B) from the plasma membrane of a smooth muscle cell (M). Most of the micro-vesicles in the terminal axoplasm contain dense granular material (↑). Note Schwann cytoplasm (S) (× 40,500)

Fig. 3. Peri-arterial axons invested by Schwann cytoplasm (S). Note areas (↑) where axons are covered only by basement membrane. Concentrations of mitochondria (M) and micro-vesicles are common in these axons. In the encircled areas several micro-vesicles are seen to contain dense granular specks (× 27,000)

The micro-vesicles, found in high concentration within the terminal axoplasm of these pancreatic peri-vascular nerves, have a diameter of 350 (±50) Å. In the normal animal, although the occasional one of these vesicles was seen to contain a dense granular material, the majority of them are without visible content in electron micrographs. However, in guinea pigs examined at intervals up to five days after injection of cobalt chloride, a high proportion (at 24 hr.—the majority) of the micro-vesicles exhibit a filling of this dense material (Figs. 1 and 2). These facts might suggest: (1) that cobalt had some specific and local action on the peri-vascular nerve terminals; or (2) that filling of a large proportion of the terminal vesicles may be a local manifestation of the response to a non-specific but stressful action of cobalt As the neurones in question are vasomotor and presumably sympathetic post-ganglionic in nature, they can be expected to elaborate noradrenaline or a comparable substance In tissues such as the adrenal medulla[7,8] and the carotid body[9], work has already indicated that the catecholamine transmitter agent is visualized in electron micrographs as a dense granular substance parcelled up within vesicles before release from the cell. It is therefore conceivable that the osmiophile granular material seen within some of the micro-vesicles at the termination of these arteriolar nerves in the pancreas (Fig 2) may be visible evidence of the presence of such a transmitter substance

HÆMATOLOGY

Relationships between Red Blood Cell Potassium Concentrations, Medial Corpuscular Fragility and Hæmoglobin Type in Merino and Southdown Sheep

WITHIN any breed of sheep there are animals which have red blood cells containing a high concentration (c 80 m equiv /litre of red blood cells) or a low concentration (c 20 m equiv /litre of red blood cells) of potassium[1] The two types are simply inherited, the latter being dominant[2]

Low-potassium Merino sheep characteristically have a very low concentration of potassium in their erythrocytes (c 12 m equiv /litre of red blood cells) and this is associated with a very low gene frequency for high potassium concentration (approx 0 07)[3] This breed appears to be particularly well adapted to the semi-arid regions of Australia This could be associated with the observation that low-potassium sheep consume less water and void less urine than high-potassium animals when both types are kept under controlled conditions[4]

Although potassium concentrations in red blood cells remained remarkably constant during long periods in sheep kept under controlled conditions[5] it has been shown recently[6] that four-fold increases in the concentration of potassium in the erythrocytes of Merino sheep in the field can occur, and that this is associated with a marked lowering of the hæmatocrit value and red blood cell count The increase in potassium concentration appears to be correlated with the severity of the anæmia and has only been recorded so far in low-potassium animals The nature of this correlation is being investigated at present

If a hæmolytic process associated with the swelling of the red blood cells is involved, there could be differences in the median corpuscular fragility between low- and high-potassium cells This preliminary point has now been investigated in Merino and Southdown sheep of known hæmoglobin type[7] and red blood cell potassium type Median corpuscular fragility determinations were carried out using the method described by Dacie[8]

Initially, the median corpuscular fragility of the red blood cells of 28 Merino ewes (23 low potassium, 5 high potassium) was examined on three occasions and a significant ($P < 0$ 1 per cent) difference between low potassium (median corpuscular fragility = 0 695) and high potassium (median corpuscular frequency = 0 625) animals was found The between animal variation was greater than the within animal variation ($P < 0$ 1 per cent), and animals with the lowest concentrations of potassium in their red blood cells within the low potassium group appeared to have the highest median corpuscular frequency values within the group

This initial observation was followed up with an experiment in which 21 Merino sheep were selected and divided into three groups—low potassium (7 animals with red blood cell potassium ion concentrations below 17 0 m equiv /litre), high potassium (9 animals with more than 17 0 m equiv /litre), high potassium (5 animals) The median corpuscular fragility was determined on each animal on 10 separate occasions The results are given in Table 1

A significant difference in median corpuscular fragility between low potassium and high potassium animals was again demonstrated in this second experiment ($P < 1$ 0 per cent), but although the difference between the high low potassium and low potassium group was in the direction expected from the high potassium results it was not significant In the high potassium group one of the animals was of the type classified as *Keβ*[5]—a type not common in British breeds—and the remaining four animals were of the type classified as *Keγ*—the normal high potassium type in British breeds of sheep This *Keβ* animal has a significantly lower median corpuscular fragility ($P < 5$ 0 per cent) than the remaining *Keγ* type animals

A similar examination of the red blood cells of 7 high potassium and 8 low potassium Southdown sheep has also been carried out and a significant difference ($P < 1$ 0 per cent) between the median corpuscular fragility of the two cell types has been found

Although no obvious correlation between median corpuscular fragility and hæmoglobin type was observed there was a correlation between hæmoglobin

Table 1 HÆMOGLOBIN TYPE, RED BLOOD CELL POTASSIUM TYPE AND MEDIAN CORPUSCULAR FRAGILITY IN MERINO SHEEP

* $P < 1 0$ per cent, † $P < 5 0$ per cent, N S , not significant No of animals in parenthesis

type and mean red blood cell potassium concentrations

All animals in a small experimental flock of Merino sheep which had been selected originally on the basis of red blood cell potassium concentrations were therefore examined along with a small flock of Southdowns The results are shown in Table 2

Low potassium (*A*) Merino sheep had a significantly higher mean red blood cell potassium concentration than low potassium (*AB*) animals ($P < 1 0$ per cent) or low potassium (*B*) animals ($P < 1 0$ per cent) Sufficient animals in the three hæmoglobin phenotypes were only available for the low potassium Merino, but other results show a similar trend—a trend which had been noted previously in relation to whole blood potassium concentrations[9]

The correlations between median corpuscular fragility and potassium type, and between potassium type and hæmoglobin type, are of interest in relation to the possible adaptive significance that the gene pairs controlling potassium and hæmoglobin types may have in some Australian environments[11,12]

Human, Cow and Rabbit Native Fibrin Powders as Anticoagulants

THE anticoagulant action of fibrin-coated surfaces on native blood and plasma has been demonstrated recently[1,2] Since the fibrin-coating process is quite laborious[3], we tested the anti-coagulant effect of a fibrin surface by simply placing native plasma in contact with fibrin powder. It was realized that the contact of native plasma with surfaces foreign to blood known to initiate coagulation, such as glass, would have to be counteracted by a large enough fibrin surface In a preceding investigation by Copley and Cliffton[4] so-called fraction I fibrin powder, prepared from a Cohn fraction I of bovine plasma by the addition of thrombin, was found to have an anticoagulant action similar to that observed in glass tubes coated with bovine fraction I fibrin Since the bovine fibrinogen (Armour) contains 40–50 per cent sodium citrate, it was not clear whether the latter was responsible for the anticoagulant effect of the fraction I fibrin powder Therefore, work has been done on native plasma fibrin powder, prepared from native plasma without the addition of anticoagulants or coagulants

Blood was drawn from the antecubital vein of healthy human subjects, the jugular vein of cows, or the rabbit's heart and immediately centrifuged for 10 min at 5,000 r p m at 0° C The undiluted native plasma thus obtained was transferred to a glass tube and allowed to coagulate at room temperature, and the clot removed with a glass rod and incubated at 37° C. in a Petri dish to speed up retraction The serum exuding from the clot was absorbed by filter paper every 10 min for 1 hr , by which time clot retraction appeared to be complete The clot was then transferred to another Petri dish and was allowed to dry in the incubator for about 21 hr after which the fibrin was ground to a fine powder 80 mgm of the powder were mixed with 1 ml of freshly prepared native plasma in a glass tube which was shaken by flicking it several times to ensure a thorough contact of the plasma with the powder. The tubes were incubated in a water-bath at 37° C. and observed for coagulation As a rule, the plasma was kept in contact with the powder for 1 hr and then was separated from the fibrin particles by low-speed centrifugation Such so-called 'fibrin-contact plasma' was then further observed for clotting in glass tubes at 37° C In all cases, regardless of the species used. coagulation never was found to occur for 7 or more hours Thereafter, the plasma was stored in a refrigerator at 4° C to counteract bacterial growth, and coagulation times were taken on successive days for periods up to several months The initial contact of 1 hr. of rabbit native plasma with cow native fibrin powder did not result in coagulation for 98 days

Table 1. EFFECT OF THROMBIN ON HUMAN, COW AND RABBIT FIBRIN-CONTACT PLASMA
(5 N I H units thrombin per 0 1 ml plasma)

Hours of contact with fibrin powder	Gelation times (sec) of fibrin contact plasma at 37° C Human native plasma exposed to human native fibrin	Rabbit native plasma exposed to rabbit native fibrin	Rabbit native plasma exposed to cow native fibrin
1	4 1	10 8	7 3
3	4 6	11 2	8 4
26]	4 9	11 0	8 9

Whenever coagulation times were taken, the fibrin-contact plasma was tested for its coagulability by mixing 0 1 ml with 0 1 ml thrombin solution, containing 5 N I H (National Institutes of Health) units, and timing the appearance of gel formation As seen from Table 1, the thrombin coagulability of the fibrin-contact plasma does not change significantly when the native plasma is in contact with the fibrin for 1–26 hr Human native plasma exposed to autologous native fibrin gives the shortest clotting or gelation times on the addition of thrombin, while this is not always the case with rabbit native plasma exposed to autologous native fibrin which exhibits longer clotting times As can be seen, rabbit plasma exposed to cow native fibrin gives shorter clotting times with this thrombin test The possibility of species-specific reactions and their variations is under investigation Frequently we observed that ageing of fibrin-contact plasma was associated with a lengthening of the thrombin clotting times However, ageing had a similar effect on oxalate plasma of the same blood withdrawal used as a control

Fibrin-contact plasma, prepared by using native fibrin from the three species, exhibited anticoagulant action This was tested by mixing 2 vol of fibrin-contact plasma with 1 vol of native plasma, resulting in markedly prolonged clotting times or in no coagulation Such mixtures always showed coagulation with the above thrombin test When 2 vol of native plasma were mixed with 1 vol of fibrin-contact plasma, coagulation occurred, and the clotting times were only slightly longer than the controls of native plasma

In contrast to fraction I fibrin powder, plasma exposed to native fibrin powder often exhibited decreases in fibrinogen content following incubation of 1 or more hr regardless of the species used for the native fibrin Such decreases amounted to 44 per cent for 2 hr of contact when compared with the control of oxalate plasma from the same blood It will have to be established whether the fibrinogen lost from the fibrin-contact plasma has been adsorbed to the native fibrin or whether it has been converted into fibrin The use of native fibrin appears to differ also in another way from that of fraction I fibrin By using the latter in both native plasma and whole blood, coagulation could be prevented; however, when native whole blood was exposed to native fibrin such an anticoagulant effect did not always result Our findings appear to show that the use of fraction I fibrin introduces possible artefacts in contrast to that of native fibrin The latter may well prove to have a more physiological anticoagulant action

Our findings suggest that if the proposed endo-endothelial fibrin film[1,2,5] did exist, it might have an anticoagulant action This might well aid in maintaining the fluidity of blood in the circulation Outside some promising practical applications, our results necessitate alteration of certain views, generally believed to be responsible for the fluidity of circulating blood and the origin of thrombosis

We are grateful to Dr R G Macfarlane, Radcliffe Infirmary, Oxford, for helpful discussions, and to Mr F A Glover, of the National Institute for Research in Dairying, University of Reading, for the preparation of cow native plasma fibrin

The work was aided by grant *H*–4793 from the National Institutes of Health, Bethesda, Md

PATHOLOGY

Persistence of Motility in Bone-Marrow Cells from the Cadaver

A READILY available source of large quantities of bone marrow would be valuable for replacement therapy in such cases as radiation accidents Cadaveric marrow may be suitable for this purpose as the cells are believed to remain viable for several hours after death[1], although no criteria of viability are given. The present work was undertaken to determine the persistence of viability of marrow cells by investigating their motility *in vitro* after somatic death

Sternal marrow (0 1–0 2 ml) was obtained by normal puncture technique from fifty human subjects at various times after death Bodies were refrigerated about 2 hr after death The range of age was 33–89 although the great majority were more than 50 years old and the ratio of males to females was approximately 2 1 An occasional sample was taken within 2 hr of death, increasing difficulty was often experienced the longer after death the attempt was made

Most leucocytes of the bone marrow exhibit some degree of motility although this is greatest in the neutrophil polymorphonuclear[2], and the present results are based for the most part on the motility of this cell Motility was considered to be present if a cell was observed to move a distance of approximately its own diameter or more during a 5-min search of the preparation

For examination of the specimen a drop of marrow was expelled on to a chemically cleaned glass slide, a coverslip applied and the edge sealed with soft paraffin The remaining marrow was mixed with bovine albumin (5 per cent) in physiological saline and used to prepare stained films for differential counting[3] This is important because for practical purposes polymorphs represent the only motile cells of the marrow and any notable reduction of their number clearly reduces the chances of observing motility The sealed preparation, on a warm stage at 37° C , was examined for motility with the 1/6 objective A 5-min search usually entailed the examination of about twelve different fields

In a preliminary examination of living subjects 12 out of 14 samples from routine diagnostic sternal marrow biopsies showed motility Of the 2 negatives one was a case of lymphocytic leukæmia, the other a case of myelosclerosis

In the post-mortem investigation, 50 results were assessed as satisfactory for analysis (Table 1) Cases were excluded from analysis because of myeloproliferative or aplastic disorders, failure of refrigeration of the body or unavailability of temperature records within 24 hr of death The presence of pyrexia before death, that is a temperature of more than 37° C at some stage during the terminal 24 hr , reduced motility and such cases are recorded separately in Table 1 Thirty-four of the fifty cases showed motility This was invariably present less than 5 hr after death and up to 20 hr in apyrexial subjects and absent in all subjects after 40 hr Oscillation of the intra-leucocytic granules frequently persisted after detectable motility had ceased McLeod and McLeod[4] believe that such oscillation is a criterion of the viability of leucocytes Whitby and Britton[2] while by inference agreeing that cells exhibiting these properties are living, state that the oscillation is a preliminary to cellular death and the present investigation supports this view Monocytic and lymphocytic motility exists[2,5,6], but was considered unimportant because of their small numbers and sluggish movement

Table 1

		Hours after death	
		0–20	> 20

	Non-motile	0	5
b	Motile	9	4
	Non-motile	3	8

a, Apyrexial, *b*, pyrexial

Cellular viability in the bone marrow of the refrigerated cadaver persists for 20 hr. or more after death. A shortening of the period of motility by ante-mortem pyrexia is in accord with Jeanneret's[7] finding that in pyrexial human subjects degeneration of cells in the stained film of post-mortem marrow occurs earlier than in the apyrexial subject. It is uncertain whether this phenomenon is attributable to a common factor, for example toxæmia, which causes pyrexia and hastens cellular death, or to the pyrexia alone increasing the metabolic rate of the cell with quicker exhaustion of its energy potential.

The clinical inference from these leucocyte motility investigations is that cells may remain transplantable longer than hitherto supposed. The technique for studying the motility is a simple one which should be useful in other ways, as for example in the examination of possible cytotoxic effects of anti-leucocytic sera.

I wish to thank Dr. J. F. Wilson for the idea from which this work developed as well as Prof. J. S. Young, Dr. R. C. Nairn and Mr. W. Brass for their interest and advice.

Effect of Phagocytosis on the Lysis of *Staphylococcus aureus* (Type 81) by Bacteriophage

CERTAIN investigations on animals have suggested the efficacy of treatment of bacterial infections with specific bacteriophage. Dubos *et al.*[1] demonstrated the therapeutic effect of *Shigella dysenteriae* phage in experimental infections in mice. Morton and Engley[2] showed a prophylactic, as well as therapeutic, effect in mice infected with *Shigella dysenteriae*. Recently, Muir and Blakemore[3] protected 70 per cent of mice lethally infected with *Staphylococcus aureus* type 80/81 with high-titred specific phage given simultaneously with the bacteria.

Work on the use of bacteriophage *in vivo* is necessarily complicated by a variety of factors, one of which is the role of phagocytes. This report will present evidence to indicate that *S. aureus* is phagocytized *in vitro* by rabbit monocytes and polymorphonuclear leucocytes, and that bacteria released from the phagocytes are susceptible to subsequent lysis by specific bacteriophage.

Staphylococcus aureus, propagating strain 81, was grown and maintained on tryptacase soybean broth (TSB). Type 81 staphylococcal bacteriophage was propagated on *S. aureus* strain 81 in the same broth, filtered through UF fritted glass filters and was stored at 4° C. Polymorphonuclear leucocytes (PMN) were obtained from normal rabbits by injecting 100 ml. of sterile 0·85 per cent sodium chloride intraperitoneally, followed by a similar injection 18 hr. later. Rabbits were killed about 3 hr. after the second injection either by bleeding or by a blow on the back of the head and the peritoneal cavities were opened aseptically. Peritoneal fluid was removed into sterile 0·85 per cent saline containing about 10γ of heparin per ml. Monocytes (MN) were obtained from rabbits given 100 ml. of sterile heavy mineral oil intraperitoneally and killed three days later. Both MN and PMN were washed three times with sterile Hanks's solution and collected after centrifugation at 1,000 r.p.m. for 5 min. at 4° C. By these methods, about 75 per cent of the collected cell population were of the desired type.

In the experiments reported here, 5 ml. of an 18 hr. culture of *S. aureus* (about 5 × 10^{10} bacteria/ml.) were mixed with an equal volume of either PMN or MN suspended in medium 199 to contain 2 × 10^{6} cells/ml. These mixtures were incubated in a roller drum revolving at 15 r.p.h. at 37° C for 45 min. Following incubation, the mixtures were immediately chilled in an ice-bath and all subsequent washings of the cells were carried out at 4° C. The original cell bacteria mixtures were washed five times with Hanks's solution and the cells resuspended at 1 × 10^{6} cells per ml. in medium 199. One of these suspensions was taken as the zero time sample. The tubes were tightly stoppered and returned to the roller drum. At intervals one tube was removed from the roller drum and washed as described. The final cell pellet was lysed in 1·5 ml. of sterile distilled water, releasing intracellular bacteria, and isotonicity was restored with an equal volume of sterile 1·6 per cent sodium chloride. Ten-fold dilutions were made in TSB in 1·0-ml. amounts. To one-half of each dilution 0·5 ml. of phage type 81 (RTD = 10^{-4}) was added. The same volume of TSB was added to the other half of each dilution. These mixtures were incubated at 37° C for 10 min. and were poured on to fresh tryptacase soybean agar plates. All plates were incubated at 37° C overnight and colony counts carried out the following day.

The colonies present on each control (*C*) plate and each test or phage-treated plate (*T*) at each time-interval and at each dilution were counted. In three experiments with PMN and two with MN from five different rabbits, the control colony count at each time-interval reflected the ten-fold dilutions made. The colony counts given in Table 1 (PMN) and Table 2 (MN) represent geometric means of the three ten-fold dilutions using cells from five rabbits at each time interval. The *T*/*C* ratios were calculated from the geometric means at each time-interval. The *T*/*C* ratio for both PMN and MN reached its peak at about the same time the intracellular bacterial count was lowest. The number of bacteria not lysed by the phage was quite constant within the time-limits of the experiments, while the number of intracellular bacteria not exposed to phage decreased steadily for about 1·5 hr. in PMN, then increased. MN, on the other hand, kept the number of viable intracellular

Table 1. *T*/*C* RATIOS AND GEOMETRIC MEANS OF COLONY COUNTS IN PMN FROM THREE RABBITS

Hr.	Colony count *T**	Colony count *C*†	*T*/*C*
0	2	475	4·2 × 10^{-3}

Table 2. *T*/*C* RATIOS AND GEOMETRIC MEANS OF COLONY COUNTS IN MN FROM TWO RABBITS

Hr.	Colony count *T**	Colony count *C*†	*T*/*C*
0	1	74	1·4 × 10^{-2}
1	1·5	13	1·1 × 10^{-1}
1·5	1·1	8	1·4 × 10^{-1}
2	1·1	7	1·6 × 10^{-1}
2·5	1·2	7	1·7 × 10^{-1}

*T**, Phage treated, *C*†, no phage treatment.

bacteria at a constant low level for at least 1 hr longer Microscopic examination revealed no viable phagocytes in either system after 24 hr

Bacteria which were not lysed by the phage after passage through either PMN or MN were later plated and incubated at 37° C for 18 hr When these bacteria were exposed to phage 81, complete lysis occurred This indicates that after passage through either PMN or MN, *S aureus* was unaffected in its susceptibility to lysis by phage 81

The meaning of the *T/C* ratio is perhaps best explained by the *T* and *C* columns in Tables 1 and 2 The number of viable bacteria in the phage-treated (*T*) columns was nearly constant in five different experiments If phagocytosis caused an increase in the number of phage-resistant bacteria, the *T/C* ratio should approach unity when the control values fell However, the approach of the *T/C* ratio toward unity was entirely due to a decrease in control counts and not to an increase in test counts. Thus the *T/C* ratio also becomes a measure of the bactericidal activity of the phagocytes and the higher the *T/C* ratio, the greater the bactericidal activity

Our results appear to be in partial agreement with the findings of other workers[4,6] Cohn and Morse[4] found that *S aureus* was not readily phagocytized in normal rabbit serum unless the multiplicity was ten bacteria/leucocyte However, *S aureus* was killed intra-cellularly only in the presence of specific immune serum Mackaness[6] reported similar findings using rabbit macrophages (monocytes) Kapral and Shayegani[5] demonstrated phagocytosis by rabbit MN and PMN at a multiplicity of 25 or 50 1, but reported no inactivation of intracellular bacteria Our results suggest that the intracellular inactivation of *S aureus* was accomplished by both PMN and MN to the point where the number of extracellular bacteria reached a critical value[5], and the cells became overwhelmed by bacteria The increase in viable intracellular bacteria probably does not represent multiplication, but may be due to additional phagocytosis[5]

RADIOBIOLOGY

Induction of Tumours in Mice with Tritiated Thymidine

We wish to record preliminary results of an experiment, in which we are investigating the possibility of inducing tumours in mice with tritiated thymidine The β-particles from tritium incorporated into deoxyribonucleic acid (DNA) from ^{3}H-thymidine produce an irradiation which primarily affects the cell nucleus, since about 90 per cent of the energy of these particles is dissipated within the nucleus This procedure, therefore, enables one to distinguish in long-range experiments the results of nuclear damage from that caused by irradiation of whole cells and tissues, and to study the importance of nuclear damage in radiation carcinogenesis It is desirable to do this, since there are many indications that alterations in deoxyribonucleic acid are involved in carcinogenesis in general. It is also commonly assumed that the tumour-inducing properties of ionizing radiations are mediated through changes in the nucleus, but there is no proof of this assumption

Table 1 INCIDENCE OF TUMOURS IN *CAF*$_1$ MICE AFTER A SINGLE INTRAPERITONEAL INJECTION OF ^{3}H-THYMIDINE

Groups	Dose-level	No of animals	Age at time of injection (months)	Age at present (months)	No of deaths	No of animals with tumours
1	1 0 μc /gm	100	new-born (1-day)	17	8	0
2	1 0 μc /gm	100	2	19	23	8
3	1 0 μc /gm	98	6–7	23–24	34	16
4	Control	170	new-born (1 day)	17	9	2
5	Control	99	3–4	20–21	21	4

Our experiment has now been in progress for 17 months It involves more groups of animals than those mentioned here The mortality among the experimental animals has been remarkably low and the capacity of tritiated thymidine to induce tumours under these conditions has not been spectacular This is of some interest in itself Nevertheless, although the total number of tumours is small, there is evidence that the death-rate from tumours is significantly higher among the exposed than among the control animals

Three groups of male and female *CAF*$_1$ mice received a single intraperitoneal injection of ^{3}H-thymidine, with a specific activity of 360 mc /m mole (New England Nuclear Corporation, Boston, Mass), at a dose-level of 1 0 μc /gm of body-weight The groups differed from one another in age at the time of injection as follows (Table 1) Group 1 consisted of new-born animals less than 24 hr old, the animals of Group 2 were 2 months old and those of Group 3 6–7 months old Groups 4 and 5 served as controls Group 4 consisted of new-born animals and those of Group 5 were 3–4 months old The controls were injected either with non-radioactive thymidine or with saline solution. The animals were permitted to live out their life-span. The diagnosis was verified in each instance by histological examination

The following types of malignant tumours have been observed among the experimental animals 6, thymic lymphoma, 9, non-thymic, disseminated lymphoma, 2, salivary gland tumour, 2, carcinoma of the skin, 5, carcinoma of the lung, 1, carcinoma of the liver (hepatocellular) The tumours were distributed equally among males and females The six tumours among the control animals were 5 non-thymic lymphomas and 1 carcinoma of the lung In animals without tumours, death could be attributed to a variety of causes, including pneumonia and intestinal infections It should be mentioned that no lung adenomata have been observed so far, either in the control or in the experimental animals

These results indicate that, at this dose-level, tritiated thymidine is a carcinogen in mice. This conclusion is supported by a similar finding in another group of 100 animals in the same experiment that were 12–14 months old at the time of injection Of these animals, 84 are now dead and 43 of them have died with tumours Although we do not at the moment have age-specific controls for this group of animals (and hence we have not listed them in Table 1), a tumour incidence of more than 50 per cent is considerably higher than that ordinarily seen in control animals of this strain and age in our Laboratory

No results are available as yet in another part of this experiment, in which we are studying the comparative effectiveness in the induction of tumours by ^{14}C-thymidine with its more penetrating β-rays.

The observations on induction of tumours by tritium-labelled thymidine are being reported now not only because they are of interest in connexion with the question of nuclear damage in radiation carcinogenesis, but also because they lend weight to the evidence that tritiated thymidine can produce significant changes in mammalian cells. Such changes have included short-term inhibition of growth[1,2], developmental and chromosome abnormalities[3,4], as well as cytogenic aberrations as shown by an increased frequency of mutations in *Drosophila*[5]. The observations in the present experiment also tend to support the opinion of Oliver and Lajtha[6], who have given warning of the hazards involved in using tritium as deoxyribonucleic acid label in man. They pointed out the possibility of mutagenic effects of the radiation on those cells that have a long life-span and several mitotic cycles.

This work was carried out under the auspices of the U.S. Atomic Energy Commission and supported by U.S.A.E.C. contract No. *AT* (II-I)-809.

Mouse Lymphoma Cells with Different Radiosensitivities

FISCHER[1] devised a medium in which murine leukæmia cells (*L* 5178 *Y*) can be grown in free culture starting from a single cell. These cells have retained their strain specificity and they will grow only in *DBA*/2 mice where they give rise to ascites and solid tumours. A logarithmically growing culture was obtained 24 hr. after transfer of the ascites cells.

We have exposed cultures to 220 kVp X-rays and observed that cells changed their radiosensitivity on being maintained continuously in culture. Fig. 1 shows the effect of irradiation on cultures that had been started from cells obtained six to ten days earlier from a mouse. Cells that had been kept going for six months continuously in culture—transfer to new medium being made twice a week—were very much more radiosensitive due to the appearance of a radiosensitive mutant. Sensitive strains were isolated by cloning from a single cell[2] and their response to radiation is shown in Fig. 2.

The effect of radiomimetic alkylating agents on these lymphoma cells has been described[3] and their response to radiation is similar. With doses up to the LD_{90}, most of the cells divide at least once and degenerate after the second day when they have grown to double their volume as measured with a Coulter cell counter. Before lysing, 10–20 per cent of the cells grow into giants having ten to fifty times the normal volume. With higher doses of radiation (that is, greater than 500 r. for the resistant strain and 200 r. for the sensitive strain) an increasing proportion of cells degenerate without having undergone division. Cells that have retained their capacity for indefinite multiplication give rise to the new population that grows up from the cultures. The fraction of 'survivors' can be calculated by extrapolation[3] and the dose response curves shown in Fig. 3 have been obtained in this way. If radiation induces a delay in mitosis which extends over several hours then the number of survivors obtained by the extrapolation method would be an underestimate. While this is improbable for reasons which we have given[3], the method was checked by determining the dilution from which an irradiated culture grows up and which must therefore contain at least one viable cell—the cloning efficiency from one cell being between 70–80 per cent[2]. The number of 'survivors' computed in this way agreed with doses up to 300 r. with the values obtained by the extrapolation method.

We have indications that mutants with varying degrees of radiosensitivity arise during growth in culture, but we have not found any strain more resistant than that carried by passage through animals. The sensitive strain divides in culture about 25 per cent more rapidly than the insensitive (compare control curves in Figs. 1 and 2) and this presumably gives them a proliferative advantage so that they establish themselves *in vitro* on continued culture. The sensitive cells have retained their host specificity for *DBA*/2 mice, but they grow less rapidly in animals than the resistant and give rise more frequently to solid tumours.

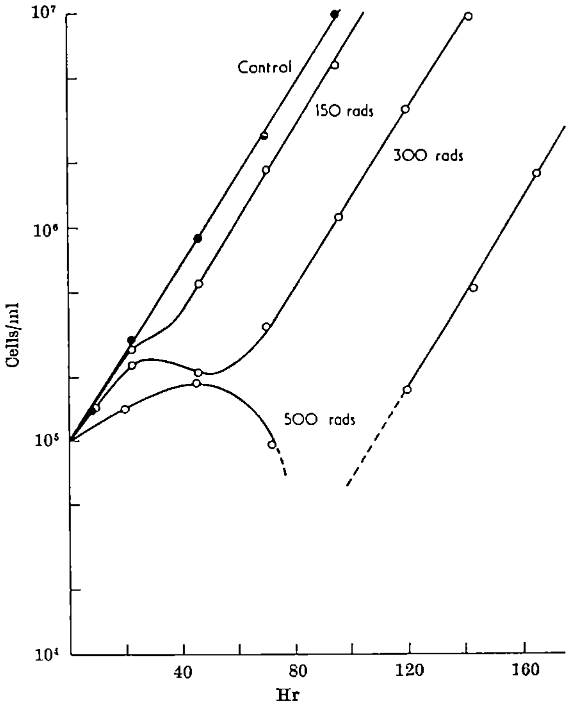

Fig. 1. Effect of irradiation with 220 kVp. X-rays (900 r./min.) on lymphoma cells in a culture which was fully aerated. The culture was diluted before reaching 10^7 cells/ml. and counted in a hæmocytometer

Cells transferred to culture from the ascites fluid of a mouse ten days earlier, referred to as a resistant strain

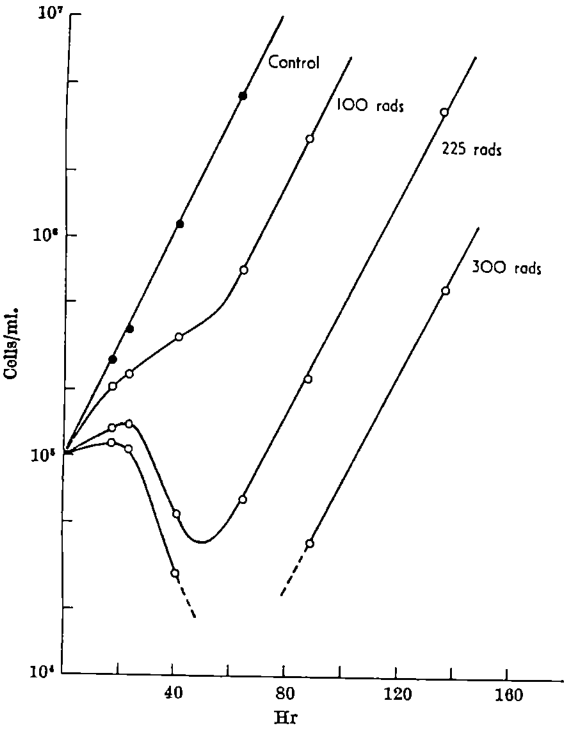

Fig 2 Effect of irradiation with 220 kVp X-rays (900 r /min) on lymphoma cells in a culture which was fully aerated The culture was diluted before reaching 10^7 cells/ml and counted in a hæmocytometer

A cloned derivative from cells continuously maintained in culture for six months, referred to as sensitive strain

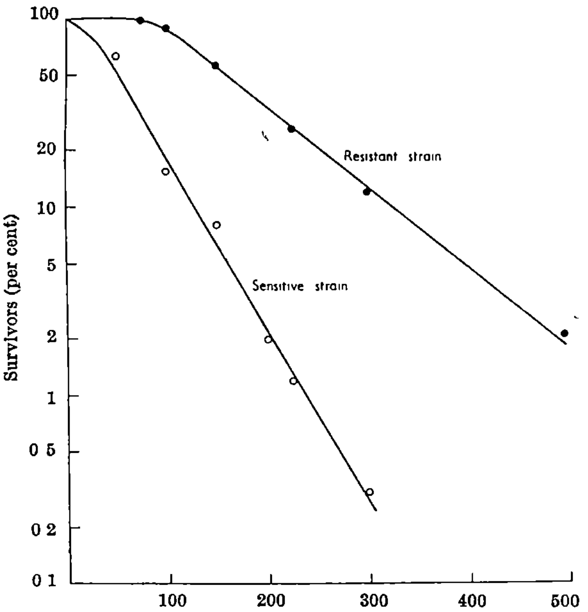

Fig 3 Fraction of cells capable of normal growth as a function of radiation dose

The average volume, as measured with a Coulter counter, of the sensitive cells is some 30 per cent greater than that of the resistant cells but the content of deoxyribonucleic acid, determined by Burton's method, is the same for both In neither type of cell, when taken from culture or from animals, could any viruses be seen in the electron microscope

These experiments demonstrate that the radiosensitivity of mammalian cells *in vitro* can change, presumably by a mutation, and suggest that deductions concerning the radiosensitivity of cells *in vivo* from *in vitro* studies are liable to serious error. Fischer[4] has shown a similar phenomenon with regard to resistance to folic acid antagonists

Effects of Iodoacetic Acid on the Incorporation of Phosphorus-32 into the Deoxyribonucleic Acid of some Radiosensitive Organs in Rats exposed to X-Rays

It is now known that iodoacetic acid is able to sensitize mice[1,2] and rats[3] to ionizing radiations as well as cultured mammalian cells[4] and bacteria (Bridges, B A , personal communication).

In a recent paper[5] we presented evidence that iodoacetic acid markedly inhibits the uptake of phosphorus-32 into the deoxyribonucleic acid (DNA) of some radiosensitive organs and of the regenerating liver in the rat This effect is similar to that shown by ionizing radiations that inhibit the incorporation of ^{32}P as well as of many labelled precursors, into DNA of dividing irradiated cells[6] Considering this common interference with DNA synthesis, we have undertaken work on the effect of the combined treatment with iodoacetic acid and X-rays on ^{32}P uptake into DNA of rat thymus, spleen and intestine

Laboratory bred male albino rats (70–90 gm) of Wistar Glaxo strain were used Lots of 16 animals, subdivided into 4 groups of 4, were used in each experiment, and treated according to the schedule reported in Tables 1 and 2

Iodoacetic acid at a dose of 40 mgm /kgm was administered intravenously This dose, as already indicated in a previous paper[5], is definitely sub-lethal X-irradiation was performed with a Picker instrument operating at 220 kV , 15 m amp , with an added filtration of 0 5 mm copper and 1 mm aluminium, at a dose rate of 26 r /min , for a total dose of 150 r

When the animals were subjected to a combined treatment, irradiation was performed 30 min after the administration of iodoacetic acid

At a dose of 25 μc /rat ^{32}P was injected intramuscularly immediately after irradiation Non-irradiated rats were given ^{32}P 36 min after the iodoacetate treatment The animals were killed with ether 2 hr after the injection of ^{32}P, and the thymus, spleen and 15 cm of the small intestine, just distal

Table 1. Corrected Specific Activity of DNA* extracted from the Spleen, the Intestine and the Thymus of Normal and Treated Animals 2 hr. After the Administration of 25 μc ^{32}P/Rat (Mean ± Standard Error of the Mean)†

	Controls	Iodoacetic acid (40 mgm./kgm.)	X-rays (150 r.)	Iodoacetic acid (40 mgm./kgm.) X-rays (150 r.)
Spleen	4·44 ± 0·76	(21 per cent)‡ 3·52 ± 0·63	(46 per cent) 2·40 ± 0·34	(56 per cent) 1·94 ± 0·36
Intestine	2·16 ± 0·19	(12 per cent) 1·90 ± 0·30	(5 per cent) 2·05 ± 0·16	(24 per cent) 1·64 ± 0·16
Thymus	3·64 ± 0·36	(23 per cent) 2·79 ± 0·35	(28 per cent) 2·61 ± 0·27 $t = 2·606$,	(50 per cent) 1·81 ± 0·14 $0·05 > P > 0·02$

* Corrected specific activity of DNA =

$$\frac{\text{specific activity DNA (c.p.m./}\mu\text{gm. phosphorus)}}{\text{specific activity of blood orthophosphate (c.p.m./}\mu\text{gm. phosphorus)}} \times 100$$

† Each figure is an average of five values obtained from the pooled organs of four animals.

‡ Figures in brackets represent percentage of inhibition.

to the pylorus, were rapidly removed. The organs of the four animals of each group were pooled for the extraction of DNA. All successive steps have been described in our previous paper[5].

Table 1 contains the values of the corrected specific activity of DNA extracted from thymus, spleen and intestine of the experimental animals. These values show an inhibiting effect following treatment with iodoacetic acid, as already described. The results, moreover, confirm the well-known inhibitory effect of radiation on ^{32}P uptake into DNA from lymphoid organs, whereas the effect is not yet detectable for the intestine at the dose-level employed. Finally they show that after combined treatment, the inhibitory effect nearly corresponds to the sum of the effects obtained by single treatments.

Experiments in which ^{32}P was injected 4 hr. after irradiation have also been carried out. The results are reported in Table 2. In this case we considered only thymus and intestine. These experiments were undertaken because the inhibition by irradiation of the incorporation of labelled precursors into DNA of radiosensitive organs reaches higher values after this time interval[7].

Table 2. Corrected Specific Activity of DNA extracted from the Intestine and the Thymus of Normal and Treated Animals 2 hr. After the Administration of 25 μc ^{32}P/Rat (X-ray Treatment 4 hr. Before ^{32}P)

	Controls	Iodoacetic acid (40 mgm./kgm.)	X-rays (150 r.)	Iodoacetic acid (40 mgm./kgm.) X-rays (150 r.)
Intestine	2·43*	(12 per cent)† 2·14	(46 per cent) 1·31	(49 per cent) 1·24
Thymus	3·09	(9 per cent) 2·82	(63 per cent) 1·13	(73 per cent) 0·82

* Each figure is an average of three values obtained from the pooled organs of four animals.

† Figures in brackets represent percentage of inhibition.

It will be noted that the effect of irradiation is much more marked at 4 hr. than at 2 hr., as expected, whereas the effect of iodoacetate is clearly lower. The response to the combined treatment in this case also nearly corresponds to the sum of the effects obtained after single treatments.

In conclusion the results reported in the present paper seem to indicate that (a), the combined treatment with iodoacetate and X-rays, at the doses used in our experiments, causes an inhibition of ^{32}P uptake into DNA corresponding nearly to sum of the inhibitions obtained by single treatments, (b), the effect of iodoacetate decreases significantly a few hr. after the administration of this substance, whereas at the same time interval the irradiation effect increases.

A possible interpretation of the results could be that the effect of iodoacetate on DNA synthesis combining with the effect of radiation may increase the total cellular damage in radiosensitive tissues.

In discussing the present results it must be taken into account that, with the doses of X-rays used in our experiments, it is possible that the reduction in DNA synthesis is the result of temporary mitotic delay and not of cell-death, whereas the sensitizing effect of iodoacetic acid has been established for cell-death. Another point to be considered is that the effect of iodoacetic acid seems to be reversible in a short time. It is not yet known whether the increased inhibition of DNA synthesis, induced by iodoacetic acid in combination with low doses of X-rays, can really affect the final cellular damage in radiosensitive tissues.

Protection by Inorganic Condensed Phosphates against the Lethal Effects of X-rays

A radioprotective effect of adenosine triphosphate has been described by Langendorff *et al.*[1], but the inorganic condensed phosphates do not appear to have been studied previously in this connexion. We have found that sodium pyrophosphate, the linear tripolyphosphate and the cyclic trimeta- and tetrametaphosphates markedly reduce the mortality in mice due to X-rays when injected intraperitoneally in neutral solution, shortly before exposure.

Female mice, weighing 20–25 gm., of *R* stock (a cross between *PCT* female and *C3H* × 101 male) were used at the age of 14 weeks. In a typical experiment 50 mice, randomized into groups of 5, were irradiated in partitioned boxes as follows: 250 kV., 15 m.amp., H.V.L. 1·2 mm. copper, distance to underside of box 60 cm., average dose-rate 73·6 r./min. Ten mice were used on each of 4 protective treatments, with 10 saline-treated controls. All 5 treatments were represented in each group during irradiation and the subsequent period of observation. Survival at 30 days was taken as the measure of protective effect. In a series of experiments on this pattern 49 saline-treated control animals died after 1,025 r., out of a total of 53 used. Thus the overall control mortality was 92 per cent, and this can be used for statistical tests with the tables of Fisher and Yates[2], but the mouse population may change its radiosensitivity and a safer though more severe test, using only the simultaneous controls, is made possible by Fisher's exact 2 × 2 contingency function as tabulated by Mainland, Herrera and Sutcliffe[3]. The results shown in Table 1 were submitted to both tests as indicated.

Since trimetaphosphate at 15 m.moles/kgm. protected 100 per cent against 1,025 r. a further experiment was done to estimate to what level it raised the radiation LD_{50}, and to compare it in this respect with *S*,β-aminoethylisothiuronium bromide hydrobromide (AET) at 1 m.mole/kgm., the highest safe dose for *R* mice. Both were given intraperitoneally 10 min.

Table 1. PROTECTIVE EFFECTS OF INORGANIC CONDENSED PHOSPHATES AGAINST 1,025 r. OF X-RAYS

Compound	Dose (m.moles/kgm.)	Time of injection (min. before irradiation)	No. of mice surviving / No. used: Exp.	No. of mice surviving / No. used: Controls (saline)
$Na_4P_2O_7·10H_2O$	0.75*	10	6/10†	1/10
,,	0.50	10	2/10	1/10
$Na_5P_3O_{10}·6H_2O$	1.00*	10	14/20‡	0/20
,,	0.75	10	3/10	0/10
,,	1.00	30	8/10‡	0/10
,,	1.00	60	2/10	0/10
$(NaPO_3)_3·6H_2O$	15*	10	10/10‡	1/10
,,	9	10	1/10	
$(NaPO_3)_4·4H_2O$	2.4*	10	8/10‡	

* These doses resulted in no deaths ascribable to toxicity. At higher dose-levels some deaths occurred shortly after irradiation, as a result of potentiation of toxicity by X-rays.

† Significant ($P < 0.005$) assuming 8 per cent control mortality (ref. 2).

‡ Also significant ($P < 0.01$) by 2 × 2 contingency test using only internal controls (ref. 3).

Table 2. PROTECTIVE EFFECTS OF TRIMETAPHOSPHATE AND AET

X-ray dose (r.)	No. of mice surviving at 30 days out of: 4 given trimetaphosphate	4 given AET	2 given saline
1,050	3	4	0
1,100	2	4	0
1,150	3	4	0
1,200	0	4	0
1,250	1	4	0
1,300	1	0	0
1,350	0	3	0

before irradiation. The results are given in Table 2. From these the normal-logarithmic maximum-likelihood estimate of the LD_{50} (by the iteration procedure of Cornfield and Mantel[4]) is 1,133 (1,059–1,213) r. for trimetaphosphate and 1,325 (1,265–1,387) r. for AET. The figures in brackets are 5 per cent fiducial limits.

Thus trimetaphosphate is significantly less protective than AET, but its lower fiducial limit, 1,059 r., is well above the LD_{50} of uninjected mice of this strain, which, though not measured simultaneously, is known to be about 860 r. There are several conceivable reasons for the protective activity of condensed phosphates, which we are investigating.

We wish to thank Mrs. D. M. R. Lowman for able technical assistance, Mr. M. J. Corp for irradiations and Dr. D. R. Peck, of Albright and Wilson, Ltd., for his interest and for generous gifts of pure chemicals.

BIOLOGY

'Bound' Gibberellin in Mature Runner Bean Seeds

RADLEY[1] has mentioned the possibility that gibberellins occur in the tissues of higher plants in both 'free' (readily extractable) and 'bound' forms. By analogy with plant-growth regulating substances of the auxin type, the hypothetical 'bound' gibberellins might be liberated by the hydrolysis of proteins of the plants being investigated. This communication describes one of several experiments in which more 'gibberellin-like' activity was detected in hydrolysed than in non-hydrolysed extracts. Radley[1] has observed that the level of readily extractable gibberellin of the seeds of the runner bean (*Phaseolus multiflorus*) falls as the seeds mature. One could visualize that the gibberellin is becoming 'bound' in some way as maturation proceeds, and because of this possibility seeds of the runner bean were chosen for investigation.

Mature runner bean seeds, mean length 28 mm., were divided into three samples, each of 120 gm. Sample *A* was homogenized in 500 ml. of a mixture of equal parts of acetone and water. (A mixture of acetone and water has been used as a primary solvent for the extraction of gibberellins from plant tissue by several workers, for example Phinney *et al.*[2], Bunsow *et al.*[3], Lang[4], Lona[5], Murakami[6], and Nickell[7].) The extract was filtered through cheese cloth, centrifuged, and the acetone evaporated *in vacuo* to leave an aqueous residue which was adjusted to 500 ml. with distilled water.

Sample *B* was homogenized in 500 ml. of phosphate buffer, *p*H 6.2, made by dissolving 136 gm. of potassium dihydrogen orthophosphate and 24 gm. of potassium hydroxide per litre of water. (This buffer has been used by Borrow *et al.*[8] as a solvent at one stage in the isolation of gibberellic acid from fungal cultures, and by Radley[1] as a solvent at one stage in experiments demonstrating the presence of gibberellin-like substances in higher plants, but it was not used as a primary extracting solvent.) The extract was filtered and centrifuged.

Sample *C* was homogenized in 500 ml. of phosphate buffer, *p*H 6.2, and the extract filtered and centrifuged. 4.0 gm. of crude ficin (L. Light and Co., Ltd.) and 6.0 mgm. of cysteine were added to the extract which was then stored at 30° C. for 12 hr. At the end of this time the extract was again centrifuged.

The three extracts were purified further in the same way: each was adjusted to *p*H 2.8–3.0 using *N* hydrochloric acid, and extracted three times with 400 ml. of ethyl acetate. The lower (aqueous) phase was discarded and the bulked ethyl acetate-rich extract reduced in volume to 50 ml. *in vacuo* at a temperature not exceeding 30° C. The extract so obtained was adjusted to *p*H 2.8–3.0 using *N* hydrochloric acid, and extracted three times with an equal volume of ethyl acetate. The bulked ethyl acetate-rich extract was reduced in volume and placed as a line across a 23-cm.-wide strip of acid-washed Whatman No. 3 chromatography paper. The chromatogram was run using a descending technique, and as a solvent the upper phase of a mixture of *n*-butanol/1.5 *N* ammonium hydroxide (3 : 1). Gibberellin A_1 (which is known to occur in the runner bean[9]) and gibberellic acid run with an R_F in the region 0.2–0.3 in this solvent system (see, for example, refs. 2, 10). When the solvent front had moved a convenient distance down the paper, some 25 cm. from the start line, each chromatogram was allowed to dry at room temperature and cut into transverse strips, each strip being in width one-tenth of the distance between the start line and the solvent front. Each strip was eluted with approximately 30 ml. of acetone in an apparatus designed by Canny[11]. The acetone was evaporated, and the dry residue stored in a deep freeze ready for assay.

Dwarf pea seedlings (var. Meteor) were used as assay plants in a technique essentially similar to that already described[10]. At the time of assay each residue was taken up in 0.8 ml. of 30 per cent ethanol.

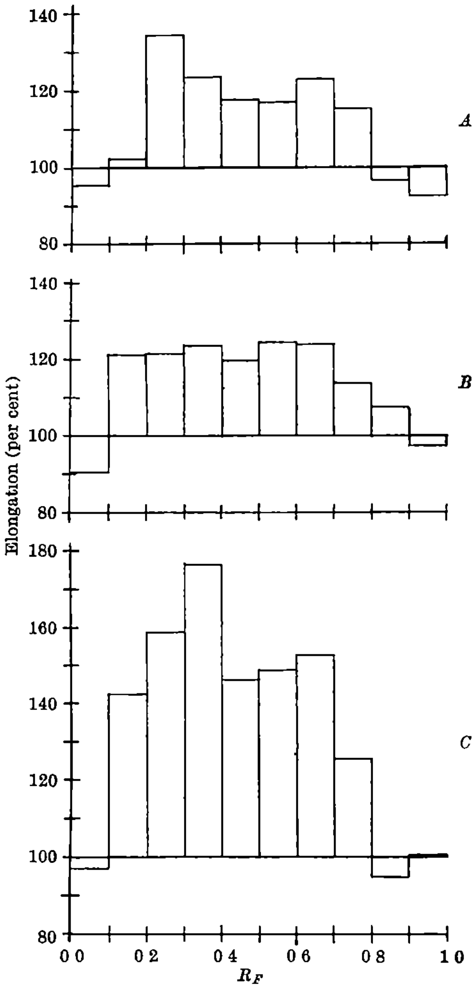

Fig 1 Percentage elongation of pea seedlings treated with eluates from chromatograms of bean extracts *A*, Extract made in acetone/water, *B*, extract made in phosphate buffer, *C*, extract made in phosphate buffer and hydrolysed with ficin

and a 0 004 ml droplet of this solution was placed on each assay plant A small puncture was made in the stem of each plant to aid penetration Ten plants were used for each solution being assayed Eluates from corresponding R_F values of the chromatograms of the three extracts were assayed in the same batch of assay plants

Fig 1 shows the mean elongation of the measured internodes of the treated plants expressed as a percentage of the corresponding internodes of the controls It will be seen that there is considerably more activity in the hydrolysed than in either of the non-hydrolysed extracts Activity is in each case spread over much of the chromatogram, but two zones are in evidence—one at R_F 0 2–0 4, the other at 0 6–0 7 By comparing the responses brought about by the extracts with those induced by known amounts of gibberellic acid, the total activities of the extracts were estimated as *A*, 0 04, *B*, 0 04, and *C*, 0 23 μgm of 'gibberellic acid equivalents' per gram fresh weight of extracted material That is, there is about six times as much activity in the hydrolysed extract. The gibberellins detected here may very well differ in their biological activities from the activity of gibberellic acid, so that the above figures should not be taken to indicate the actual levels of gibberellin in the tissue

Other extracts of mature runner beans have shown increased activity due to enzyme hydrolysis, while extracts of young beans have in general shown no such increase Negligible activity was detected in an extract subjected to alkaline hydrolysis In all cases buffer has proved to be at least as effective an extracting solvent as a mixture of acetone and water

I am indebted to Dr M J Canny for his interest and advice during the course of these experiments

Gibberellic Acid and Chlorophyll Content of Leaves of Meteor Peas

The present investigation was to determine whether the effect of gibberellic acid in causing chlorosis was due to an interference in chlorophyll formation or to some secondary effect[1] *Pisum sativum* var. Meteor were grown in the field in a block arrangement, and alternate rows were treated with gibberellic acid (*Y F* 4961, Plant Protection, Ltd) Gibberellic acid diluted to 100 p p m with water was sprayed on the upper surface of the plant 10 days after emergence

Three days after spraying slight chlorosis of the third leaves was apparent Chlorosis increased in intensity in leaves expanding afterwards, but no change in colour was observed in the first and second leaves The internodes from the second upwards showed a 180–250 per cent increase in length over the controls Measurement of the length and breadth of a random sample of leaves of control and treated plants was made 7 and 14 days after spraying The total number of cells[2], chlorophyll content[3], and the fresh and dry weight of a finite area of leaf were measured for disks of known area punched from a similar position 8 and 15 days after spraying Measurements were also made of individual palisade cells in a similar region from which the disks were punched, and the depth of the sections measured to find the thickness of leaf in this area

Measurements of the leaf dimensions showed that those of treated plants, with the exception of the oldest leaf, were longer than those of the controls, but of similar breadth Palisade cells in treated material tended to be broader and shorter in length The results given in Table 1 show that total chlorophyll tended to be slightly less in treated leaves expanded after spraying However, chlorophyll content expressed in terms of dry weight, fresh weight, or weight/cell shows no such decrease Cell counts show that treatment with gibberellic acid resulted in a significant decrease in the number of cells per unit leaf area in leaves not fully expanded at the time of spraying. This decrease is related to the decreased thickness of the leaf

Table 1

Leaf No	Total chlorophyll (mgm /90 mm ²)		Chlorophyll gm /100 gm fresh weight		Chlorophyll gm /100 gm dry weight		Chlorophyll per cell, μgm × 10⁻⁵		Ratio chlorophyll a/b		Leaf thickness (μ)		No of cells/ 90 mm ² × 10⁶	
	Control	Gibberellic acid	Control	Gibberellic acid	Control	Gibberellic acid	Control	Gibberellic acid	Control	Gibberellic acid	Control	Gibberellic acid	Control	Gibberellic acid
	8 days after spraying													
1	128 ± 21	129 ± 23	0 14 ± 0 02	0 14 ± 0 03	1 4 ± 0 2	1 4 ± 0 3	5 9	6 2	2 6	2 5	388 ± 53	398 ± 24	2 16	2 10

3	101 ± 14	94 ± 11	0 13 ± 0 01	0 14 ± 0 03	1 2 ± 0 1	1 4 ± 0 2	3 9	4 5	3 2	3 3	369 ± 43	256 ± 32	2 62	2 11
4	63 ± 3	59 ± 11	0 12 ± 0 01	0 14 ± 0 02	0 82 ± 0 2	1 1 ± 0 2	1 8	2 1	2 8	3 3	209 ± 37	145 ± 10	3 73	2 85
	15 days after spraying													
2	106 ± 3	99 ± 5	0 098 ± 0 01	0 12 ± 0 01	0 94 ± 0 05	0 89 ± 0 06	4 4	5 0	2 6	2 7	—	—	2 40	1 85
3	100 ± 25	81 ± 29	0 12 ± 0 02	0 12 ± 0 02	0 91 ± 0 07	0 91 ± 0 1	3 6	4 2	2 9	2 7	288 ± 48	246 ± 20	2 77	1 94
4	72 ± 11	61 ± 14	0 12 ± 0 01	0 13 ± 0 01	0 93 ± 0 06	0 98 ± 0 1	2 3	4 0	3 2	3 1	262 ± 35	169 ± 32	2 49	1 55
5	80 ± 18	57 ± 11	0 15 ± 0 02	0 16 ± 0 02	1 2 ± 0 3	1 1 ± 0 1	2 3	3 0	2 9	2 8	185 ± 39	140 ± 15	3 46	1 90

It can be concluded from the above results that the appearance of chlorosis in material treated with gibberellic acid is not due to lower chlorophyll content per cell but is apparently an artefact arising from the effect of gibberellic acid on leaf expansion This results in the treated material having leaves of greater surface area which are thinner than the controls and thus having a shorter optical path for absorption of light Similar results were obtained in two successive seasons, the hot bright summer of 1959, and the cooler wet summer of 1960 Our results are in agreement with those of Wolf and Haber[4] In their case with wheat seedlings an influence of nutritional factors on the chlorophyll content became apparent in older plants, this was not observed with the meteor pea plants grown in the field

Effect of Auxin on the Osmotic Value in Pea Stem Sections

The osmotic concentration in pea stem pieces was found to be increased by indole-3-acetic acid (IAA) when they were smeared with lanolin paste of IAA and kept at constant humidity[1] Treatment with auxin solution was avoided in this case in order to exclude the possibilities of a secondary osmotic change due to water absorption and leaching of solutes from cells In the experiment to be reported here, however, auxin solution was used in order to observe an osmotic change immediately following the auxin action

Excised pieces, 10 mm long, from etiolated stems of Alaska peas were weighed and floated on 10 and 200 mgm /litre solutions of IAA and on water at 25 5° C Samples were withdrawn at intervals, blotted with filter paper, and the freezing point depression of tissue juice was determined to the nearest 0 01° C [1], using a thermojunction The freezing point of the juice was around − 0 56° C before the tissue was introduced into the solutions Changes of freezing point in the solutions are shown in Fig 1

The osmotic concentration at first increased, following exposure to IAA, and then decreased rapidly after 30 min or so In the water control, on the other hand, no temporary increase in osmotic concentration was observed Experiments not presented here showed that phenylacetic acid and acetic acid in the molar concentration equivalent to 200 mgm /litre of IAA did not cause a rise in osmotic concentration as IAA did

No significant difference in the rate of water absorption was found between the two auxin-levels in the first 30 min, even though the osmotic values at the two levels differed greatly Water permeability may have been a limiting factor

The drop in osmotic concentration may be ascribed to (1) dilution due to water absorption (which is calculable) and (2) leaching of solutes from cells to outer solution The more rapid drop in the presence of IAA may probably be ascribed to an increased permeability[2-6]

It has been reported that the osmotic concentration is increased by IAA[7,8] It is, however, worthy of note

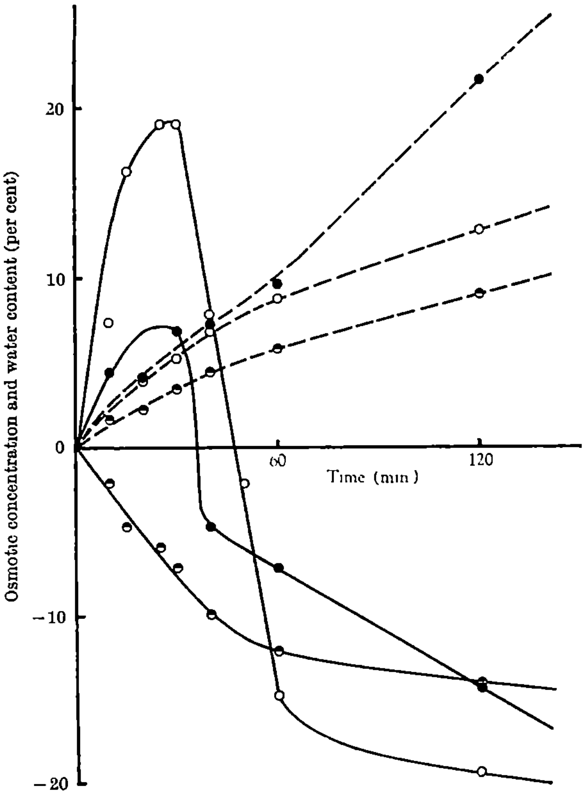

Fig 1 Water absorption (- - -) and osmotic concentration (—) of pea stem sections treated with water (◐), and 10 mgm (●), and 200 mgm (○), of indole-3-acetic acid per litre

that the osmotic effect appears in such a short time as shown here In order to see how rapidly the cell wall extensibility is affected by auxin, longitudinal tension of 2 5 gm was applied to stem pieces soaked for various periods in 200 mgm /litre solution of IAA By this method[9,10], an increase in extensibility became observable in 15 min of auxin action, but not in 10 min Hence the osmotic change occurs earlier than the change in cell wall extensibility

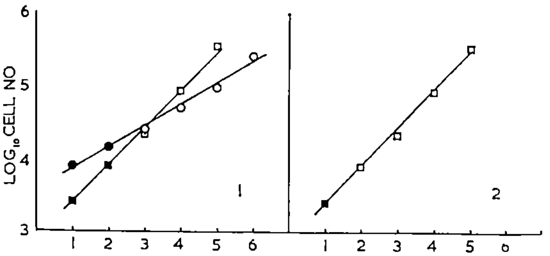
Determination of Cell Numbers in Leaf Primordia

Sunderland and Brown[1] have pointed out that there are two major problems involved in the determination of the number of cells in leaf primordia (1) numerous macerating fluids[2] tend to disintegrate the relatively delicate cell wall system of leaf primordia and (2) owing to the minute size of leaf primordia and their relatively small number of cells, fragmentary losses are a serious source of error when counting by hæmocytometer slide after dilution

A method is suggested here which mainly overcomes these difficulties and has been used successfully for the second to the sixth primordia of tomato (*Lycopersicon esculentum*) and tobacco (*Nicotiana tabaccum*) stem apices It has greater ease and rapidity of counting than the squash method originally used by Sunderland and Brown[1] and can be directly integrated with values obtained by other techniques (for example chromic acid) for larger leaflets[3]

Primordia were excised under a dissecting microscope using a small splinter from a safety razor blade gripped in a holder Immediately after excision the primordia were placed in acetic acid/ethanol, 1 1 (v/v), for at least 10 min at room temperature and then treated with *N* hydrochloric acid for 8–15 min at 60° C in an oven, depending on the size of the primordia[1] The primordia were immersed in the liquid in wells constructed by placing on a slide up to three rings cut in lengths of 3 mm from polyvinyl chloride tubing (10 and 15 mm diameter) with a razor During the treatments the slide rested on the rim of a watch glass, which stood in a Petri dish containing the same liquid as the slide in order to reduce evaporation of the liquid[1] After the removal of each reagent by applying filter paper strips to the base of the outside of the well, the polyvinyl chloride rings were removed with a pair of forceps without disturbing the primordia The primordia were then removed from the slide under the dissecting microscope, using a fine glass rod or a filter paper strip, and transferred to 10 × 0 6 cm (approx) specimen tubes containing a precisely known volume —between 0 3 ml and 1 0 ml —of 0 1 *M* ethylenediaminetetraacetic acid in 5 per cent (v/v) aqueous butanol mixture at *p*H 8 (ref 4) using ammonia solution to adjust the *p*H The tubes were tightly stoppered and the primordia in the ethylenediamine tetraacetic acid/butanol mixture were incubated overnight at 30° C The primordia were then macerated gently with a small syringe (1 0 ml) to which a finely drawn out piece of glass capillary tubing was attached with surgical polythene tubing After maceration, 0 1 ml of 1 per cent (w/v) malachite green in water was added to each tube to produce a minimum of 0 4 ml for the smallest primordia, for larger primordia the volume was made up to 1 or 2 ml and the volume of the stain increased proportionally The suspension was again drawn a few times through the syringe to ensure uniform distribution of cells and 0 2 ml was transferred to a hæmocytometer slide (Fuchs–Rosenthal, depth, 0 2 mm area, 1/16 mm^2) and counted Duplicate estimations on separate aliquots were made for each primordium



Figs 1 and 2 Tomato, ○, hæmocytometer, ●, squash, tobacco, □, hæmocytometer, ■, squash

Preliminary results obtained with this method for the second or third and older primordia of tomato and tobacco plants aged 8 weeks in November and grown in water culture are shown in Figs 1 and 2, in relation to those obtained for the first and second primordia by the squash method of Sunderland and Brown[1] For the particular purpose of these comparisons plants about 8 weeks old were selected when the youngest primordium visible on the apex (numbered 1) had attained what was judged to be almost the maximum size before the next was due to appear In Fig 2, all primordia except the first were measured by the hæmocytometer method

The numbers of cells counted for each aliquot of 0 2 ml ranged between 60 and 600 according to primordial position and species The standard error of the means of 18 pairs of counts was ± 3 7 and the mean difference between pairs did not differ significantly from zero These counts were about 0 5 or 1 per cent of the total cell number for the smaller primordia (Nos 3 or 2) and 0 1 per cent of the total for the sixth primordium The extension of counts to more mature leaves using chromic acid maceration[3] showed a linear relationship for log cell number up to about the eighth or ninth leaf in both species

Potential Productivity of Marrow Stem and Thousand-headed Kale

SEED of marrow stem kale was sown in August and the plants transplanted to permanent quarters in October Approximately half of the plants flowered in the following spring The non-flowering plants continued their vegetative growth and were sampled by the 'perfect plant method' in the following October Dry-matter production (excluding roots) was equivalent to 9·7 (from an August 4 sowing) and 7·6 (from an August 19 sowing) tons per acre If we neglect the weight of the plants at transplanting time this represents a complete year's production of dry matter Plants from later August and September sowings, transplanted in April, produced by October 8·6 and 6·2 tons of dry matter (excluding roots) per acre Comparable production figures for thousand-headed kale from these later sowings were 7·7 and 6·2 tons These figures represent a production of dry-matter two or three times as great as that obtained when the kales are sown in the traditional manner in April, and much in excess of that obtained with other agricultural crops They may be compared with the annual dry matter production of 7·6 for the evergreen *Pinus*[1], 3·2 for birch[2], and 1·6–5·6 tons per acre for natural herbaceous vegetation[3]

The high productivity of the kales undoubtedly results from their early development of a full leaf cover, the autumn-transplanted marrow stem kale having a mean leaf area index of 0·4 by early May and one of approximately 2·0 by the end of that month, which compares with a leaf-area index of 0·06 at that date for a commercial crop sown in April as is customary, and which yielded 3·3 tons of dry matter per acre

Cytochrome c Oxidase, the Terminal Oxidase

Table 1 THE EFFECT OF CARBON MONOXIDE/OXYGEN AND NITROGEN/OXYGEN GAS MIXTURES ON THE RESPIRATION OF *Iris* RHIZOME AND BAKER'S YEAST

Organisms	Inhibitor	Per cent inhibition as compared with controls in an atmosphere of 95 per cent nitrogen/5 per cent oxygen
Rhizome tissue	95 per cent carbon monoxide/5 per cent oxygen in dark	60
	95 per cent carbon monoxide/5 per cent oxygen in light	0
Baker's yeast	95 per cent carbon monoxide/5 per cent oxygen in dark	60
	95 per cent carbon monoxide/5 per cent oxygen in light	0

were split lengthways, rinsed and used immediately The uptake of oxygen of the 'half-cores' was measured in Warburg manometers at 10° in a damp atmosphere of 95 per cent carbon monoxide/5 per cent oxygen or 95 per cent nitrogen/5 per cent oxygen both in the light (250-W mercury vapour lamp) and in the dark A suspension of baker's yeast in 0·1 *M* phosphate buffer, *p*H 6·0, was also used as a comparison and the dark carbon monoxide inhibition was 60 per cent in both cases and fully reversed in the light (Table 1)

It is generally accepted that cytochrome *c* oxidase is the terminal oxidase of baker's yeast and the fact that a similar light-reversed carbon monoxide inhibition of 60 per cent was obtained with *Iris* is evidence that a similar state of affairs exists in this tissue These results would support the widely held view that cytochrome *c* oxidase forms the main terminal oxidase even in mature plant tissues[2]

GERONTOLOGY

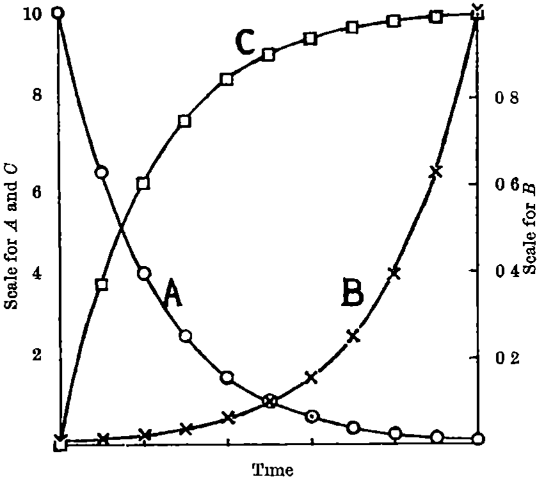

Fig 1 Graphs against time of (*A*) specific growth-rate in arbitrary units, (*B*) its reciprocal, (*C*) its negative (deficit below its maximal value)

looking into the basis for Minot's view on the rate of senescence Most people probably believe that his relation implies that the state of senescence is proportional to the reciprocal of the specific growth-rate and accept it on this understanding. However, if the reciprocal of the values of the specific growth-rate in Fig 1,*A* are plotted on a suitable scale (Fig 1,*B*) the curve is a climbing exponential, convex and not concave to the time axis, the rate increasing most slowly at first and progressively more rapidly afterwards ; this is in keeping with the specific death-rate and other criteria, as well as with intuitive judgments Minot's relation really assumes that the state of senescence is proportional to the negative of the specific growth-rate (Fig 1,*C*) or more precisely to its deficit below an initial maximal value, that is, to $(k-x)$ rather than to k/x. This has much less appeal on the score of biological rationale, and so there is neither a very strong argument, nor much evidence, in favour of his relation, with its grotesque paradox should greatly clarify the situation and but is maximal between sixty and seventy years of age, and slower in the very old Consequently the specific growth-rate increases again in old age There is direct evidence of this in the rate of cell division in some tissues[5]. Other properties also reverse their trend in later life, and if this is true of senescence, also, it may provide some slight justification for the popular jest about second childhood[5]

MICROBIOLOGY

Physical Conditions as Important Factors for the Regeneration of Naked Yeast Protoplasts

In our previous papers[1] we have discussed the growth and regeneration of naked yeast protoplasts of *Saccharomyces cerevisiae* obtained by means of cell wall autolysis In the former experiments the growth and regeneration took place on solid synthetic media The frequency of regeneration was low on these media, while nearly all the protoplasts were capable of growth, in fact only about 1 per cent regenerated into new yeast cells (in a complicated manner formerly described).

Studying the factors influencing regeneration, we have found that practically all the protoplasts are capable of regeneration under suitable conditions We were successful in finding conditions under which the protoplasts regeneration is nearly 100 per cent

Protoplasts do not regenerate in liquid media at all The frequency of regenerations is very low on the surface of solid agar media and the chemical composi-

[illegible] *Iris pseudacorus* L.

WHILE it is generally agreed that cytochrome *c* oxidase is the terminal oxidase of embryonic plant tissues, some workers doubt if it has this role in older plant tissues as well[1] It is of interest that a mature tissue such as the rhizome of *Iris pseudacorus* L , obtained from a Lancashire marsh, should contain a cytochrome system which might reasonably be claimed to account for the oxygen uptake of the tissue The rhizome tissue used was cut from within the endodermis of the current year's growth, 1 0 cm or farther from the meristematic region The cells were typical parenchymatous cells except that the tissue also contained some vascular cells

The presence of a cytochrome system was apparent from the absorption spectra of slices of reduced tissue when examined with a direct-vision spectroscope The positions of the maxima of the absorption bands in the visible region corresponded approximately with the $(a + a_3)_a$, b_a and c_a cytochrome bands of a reduced yeast suspension with which they were compared, except that the b_a and c_a bands of the *Iris* tissue were not distinctly separated

Cores of tissue were used for respiration experiments These cores 1 cm diameter and 2 5 cm long

---

WE owe to Minot[1] a startling paradox [illegible] view that the rate of senescence is most rapid at the beginning of life and slowest at the end to quote the fourth of the laws by which he summarized his conclusions, 'Senescence is at its maximum in the very young stages and the rate of senescence diminishes with age" The justification for his view was that the intrinsic or specific growth-rate of the tissues decreases most rapidly at the outset and progressively more slowly afterwards, following a roughly exponential die-away curve (Fig 1,*A*) It seemed a reasonable assumption that the senescent state is related to the loss of the power of growth and so the paradox has been widely accepted, notwithstanding the intuitive conviction that the process of senescence is not significant until after the prime of life The postulated initial, rapid stages of senescence have to be shrugged off as 'insensible'

However, there are properties relevant to senescence which can be measured and which are not found to increase most rapidly at the outset the specific death-rate, for example, is minimal not at the outset but in late childhood , it then begins to increase slowly, with progressive acceleration[2], and not most rapidly at first It is therefore worth

Even the reciprocal relationship between senescence and growth-rate is only acceptable with a certain stipulation In man increase in height and weight ceases around the age of thirty At this early age, therefore, when he is manifestly in his prime, the reciprocal of the specific growth-rate tends to infinity Soon after this time actual shrinkage begins, and the specific growth-rate becomes negative Consequently, its reciprocal now swings sharply to $-\infty$ and then climbs to finite but permanently negative values To convert this into biological sense it is necessary to assume that the relevant growth-rate is not mere increase in size but that of growth in the broadest sense, including maintenance and repair—perhaps in fact anabolism *in toto*[3] Growth in this sense remains positive throughout life, though eventually unable to keep pace with catabolism It does not imply an infinite rate of senescence at any stage, therefore With this modification, moreover, senescence is not maximal at the age of thirty, there is no discontinuity at that age, anabolism continuing a smooth decline

There is a further point which deserves attention The rate of shrinkage in man, as shown, for example, by Quetelet's data[4], does not increase to the end

---

tion of the media does not influence appreciably the frequency of regenerations But nearly 100 per cent regeneration can be achieved 24 hr after inoculation by cultivation of protoplasts inside solid media containing gelatin (see Table 1) (On the surface of agar media regeneration does not take place before 5 days)

It is seen from Table 1 that the concentration of gelatin is important Regeneration is not accomplished in gelatin with concentration less than 15 per

Table 1

Medium	Mode of cultivation	Concentration of gelatin (per cent) 0	5	10	15	20	30	40
Synthetic	On the surface of gelatin	0	0	0	0*	0*	0*	0*
	Inside gelatin	0	0	0	Reg + –	Reg	Reg	Reg
Synthetic + 30 per cent of gelatin hydrolysate	On the surface of gelatin	0	0	0	0*	0*	0*	0*
	Inside gelatin	0	0	0	Reg + –	Reg	Reg	Reg

* Only the protoplasts which have penetrated into gelatin regenerate

0, No regeneration, *Reg* + –, sporadic regeneration, Reg , nearly all the protoplasts regenerate cent (at a temperature of 22° C) Protoplasts growing on the surface of gelatin of any concentration do not regenerate, but protoplasts have proteolytic activity and can penetrate into the gel where they can regenerate The contact of a protoplast with gelatin gel is not sufficient for regeneration, protoplasts have to be surrounded by the gel Further, we can see from Table 1 that regeneration does not take place in media containing 30 per cent of hydrolysate of the gelatin, unless a gel of unhydrolysed gelatin of proper concentration is used Thus, regeneration is not influenced by the chemical composition of gelatin Regeneration is not, likewise, accomplished in liquid media with albumin of different concentrations

It may be concluded, therefore, that nearly all the yeast protoplasts have not only the ability to grow but also capacity for regeneration, and that physical conditions, that is, surrounding of protoplasts by the gel of certain consistency, are important for regeneration The explanation of the mechanism of this process will be considered later

These results, as well as the micro-cinematographic registration of the whole process, seem to disprove the opinion of Eddy and Williamson[2] that in naked yeast protoplasts there is not an autoregeneration, but a formation of cells by budding of spores accidentally present in the suspension of protoplasts

VIROLOGY

Transmission of Clover Phyllody Virus by *Aphrodes bicinctus* (Schrank) in North America

Phyllody, a disease of clovers, occurs in eastern North America and appears to be similar or identical to the disease present in England, continental Europe

six healthy plants later showed signs of virus infection (chlorosis, bronzing and stunting) and five out of the six plants developed phyllody symptoms The remaining plant failed to flower

Three adults of *A bicinctus*, collected at Lavaltrie, Quebec, from a field of clover where phyllody was naturally present, were allowed to feed on disease-free ladino clover for one week to determine if they carried the virus They were then allowed to feed for nine days on ladino clover which was infected with phyllody virus, after which they were transferred to virus-free ladino clover plants at irregular intervals until the last insect died. The leafhoppers were not viruliferous when captured but became infective after feeding on diseased plants They transmitted the virus to each of four healthy test plants on which they were serially transferred These plants later displayed typical leaf symptoms Three out of the four clover plants developed phyllody

These experiments demonstrate that *A bicinctus* is capable of transmitting the virus that causes clover phyllody in North America A search for additional vectors of the virus in eastern Canada is in progress

This is believed to be the first report of transmission of the virus causing clover phyllody by a leafhopper in North America

Grateful acknowledgment is extended to Dr W R Richards, Entomology Research Institute, Ottawa, for identification of *Aphrodes bicinctus* (Schrank)

Movement of Tobacco Mosaic Virus through Epidermis of *Nicotiana glutinosa* Leaves

were taken 3, 3½, 20 and 21 hr. after inoculation. The experiment was repeated several times. No local lesions appeared on the stripped area even 48 hr. after stripping, whereas about 150 local lesions appeared 23–26 hr. after inoculation on the rest of the leaf. On the other hand, bio-assays of areas devoid of epidermis revealed that virus was always present even after only 3 hr. In another experiment, portions of the epidermis of detached leaves were stripped off and 20 hr. later the stripped areas were then inoculated in the usual manner. No local lesions appeared on the stripped areas.

Stripping of the upper epidermis is very difficult, presumably because the epidermal layer is tightly connected to the underlying palisade cells. The strips were examined under the low magnification of a compound microscope and appeared to consist of the epidermal cells plus a thin portion of the palisade layer. The palisade layer was therefore rather heavily damaged in the stripping process.

It appears that in detached *N. glutinosa* leaves tobacco mosaic virus penetrates through epidermal strips into the palisade in less than 3 hr., but that for some reason under my conditions, the presence of epidermis is required for necrotic lesion formation.

This work was done while I was a research assistant at the University of California and was supported in part by a grant No. *E*-3415 from the National Institute of Allergy and Infectious Diseases, U.S. Public Health Service.

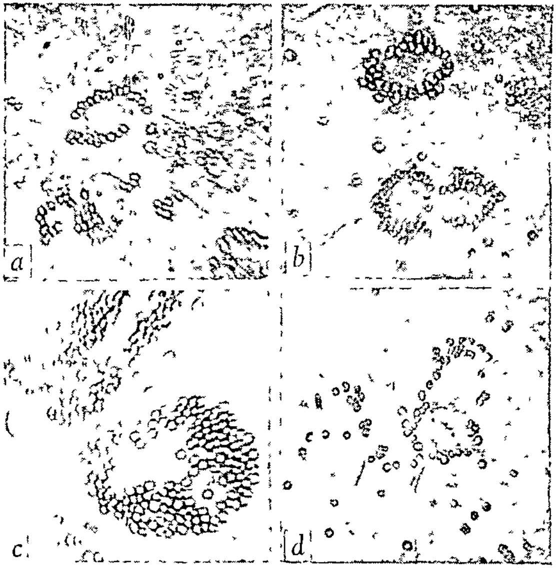

Fig. 1. Utilization of sheep red blood cells in the hæmadsorption test for myxoviruses

(Japan 305), *B* (Lee and *B*54), and mumps virus. Controls consisted of normal uninoculated cells and infected cells to which a 1 : 10 dilution of specific rabbit virus antiserum or normal rabbit serum was added 10 min. prior to the addition of sheep red blood cells. In all cases the controls showed no hæmadsorption. It was also possible to show hæmadsorption to sheep red blood cells with an influenza *C* strain in a continuous line of cells isolated from rabbit heart.

Fig. 1 shows hæmadsorption 'rosettes' seen with myxoviruses and the kerato-acanthoma cell line. Very little difference is seen between the response in the case of mumps virus and two of the influenza *A* strains (*PR*8, and *FM*1) tested (Figs. 1*a* and *b*). In the case of the *A*2 strain (Fig. 1*c*), however, the 'rosettes' often take on a much heavier appearance. The reason for this occurrence is not known, but it may be related to the amount of 'free' virus on the

TIMBER TECHNOLOGY

Effect of Temperature on the Strain Recovery in Wood

UNTIL recently, strains occurring beyond the limits of plastic creep in wood were, because of the similarity to creep in crystalline solids, identified with micellar creep in cellulose and considered as plastic strains[1] Investigations carried out by Ivanov[2], in which swollen wood was subjected to cyclic loading and unloading with compression stresses above the limit of plastic creep along the fibre direction, showed that after each cycle of loading and unloading, both elastic and residual strains are increasing Moreover, Ivanov found that strains occurring during compression beyond the limits of plastic creep, when wood is compressed along the direction of fibre length until the moment of showing symptoms of failure, were not connected with microscopic displacement of wood structure components On the other hand, strains occurring beyond the limits of plastic creep when wood is compressed across the fibre direction are, to some extent, related to the deformations of cell cross-section shapes[3].

On the basis of present available research results, strains occurring in wood can be divided into three categories elastic strains, elastic lagged strains, and plastic strains

Investigations on the stress relaxation in wood showed that stresses are undergoing relaxation with the passage of time regardless of whether they are higher or lower than those occurring at plastic creep limit[4,5].

Moisture content and temperature of wood are exerting a decisive effect on the relaxation of stresses in such a way that the increase of moisture content and temperature is accelerating stress relaxation[6].

We have now determined the effect of temperature on the strain recovery in wood after compression across the fibre direction The detailed results of these experiments are to be published in the near future Experiments which are the subject of this report were conducted on green, maximum swollen beech-wood (*Fagus sylvatica* L) Samples of dimensions 20 × 20 × 30 mm were subjected to compression with a thrust amounting to 120 per cent of ultimate strength (σ_D) For ultimate strength, the stresses corresponding to the limit of plastic creep were assumed

Experiments consisted of the following independent treatments (1) loading of wood at 20° C followed by heating it to 100° C after a lapse of 24 hr from the moment of unloading, (2) loading of wood at 20° C followed by heating it to 40, 60, 80 and 100° C immediately after unloading, (3) loading of wood at 20, 40, 60, 80 and 95° C and observing the strain recovery at the same temperatures

Because the wood was wet and in a state of maximum swelling, water used as a heating medium was raised to the predetermined temperature in order to eliminate the possible effect of wood moisture-content changes on the results of observations In the evaluation of test results, the correction resulting from anomalies of the coefficient of linear temperature strains in moist wood was introduced

Maximum swollen wood, when heated in w
is subject to elongation in a tangential di
and contraction in radial and lo
directions[7-9]

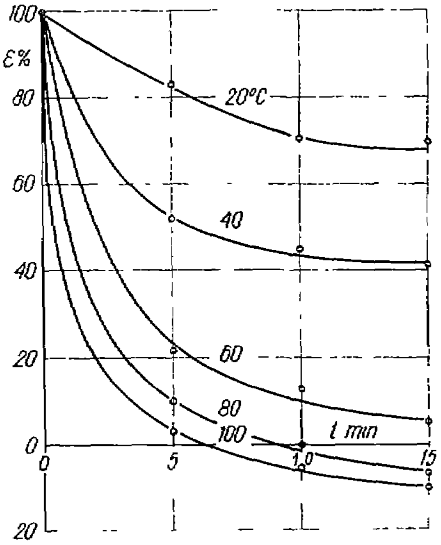

Fig 1 Effect of temperature on the strain recovery in beech-wood compressed across the fibre direction

Experiments in the first treatment showed that wood, like other substances with large molecules of chain structure[10], is also subject to the thermo-elastic strain recovery effect This phenomenon appeared also when the temperature of wood, previously steamed for 6 hr, was increased from 20° C to 100° C

The effect of temperature on the strain recovery, expressed in percentage of strain, and observed immediately after unloading, is illustrated in Fig 1 It is evident that the rate of strain recovery increases with the rise of temperature Also it may be noted that at 80° C and 100° C, wood sample dimensions in the direction of compression exceed initial dimensions in that direction.

From Fig 2 it may be seen that wood previously heated to various temperatures and loaded with the same compressing force (120 per cent σ_D) recovers its initial dimensions almost completely when heated during loading, and after unloading maintains these dimensions regardless of the magnitude of strain which occurs during loading

From the results obtained it is evident that when maximum swollen wood is heated it acquires a high degree of elasticity There is a probability that the total strain occurring at some moment after unloading the wood sample, and regarded commonly up to now as a plastic strain (durable, non-recoverable), is only apparently plastic, being the sum of
and real elastic strains The
elastic strain is intrinsically
temperature after unloadin
of compressing beec
the strain, whic
one, proved
merely tem

The ab
wood e
prope
st

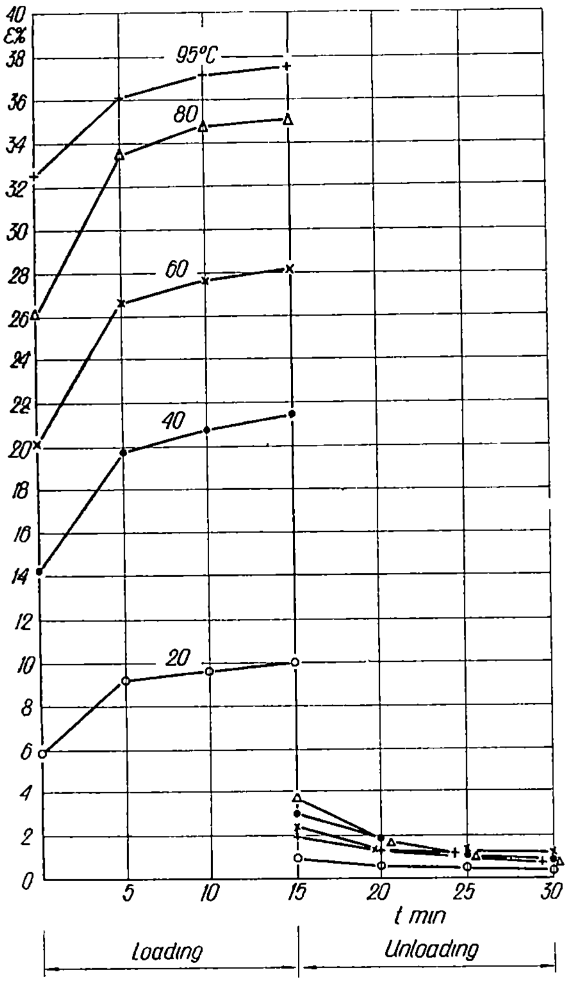

Fig 2 Effect of temperature on the strain and strain recovery in beech-wood loaded with equal compressive force of 120 per cent σ_D in the tangential direction

In view of these facts, the problem of dividing apparent plastic strains in wood into thermo-elastic and real plastic strains is of great importance

On the basis of these experiments we propose the partition of strain recovery in wood according to the scheme presented in Fig 3 Only those strains which remain after the first thermoplastic effect can be considered as the real plastic strains (ε_{rps}) It was experimentally corroborated that further increase of temperature, for example in time t_3 (Fig 3), results in very little, if any, increase of strain recovery. In order to determine the value of real plastic strain caused by compression of moist wood across the fibre direction, it is sufficient, it seems, to separate the thermoplastic strain (ε_{tes}) from apparent plastic strain (ε_{aps}) by accelerating strain recovery by raising the temperature of the wood

olindale Avenue,

EDUCATION FOR LEADERSHIP

IN his presidential review to the Rockefeller Foundation for 1960*, Mr G J. Harrar, who succeeded Mr Deak Rusk as president on July 1, 1961, pays particular attention to the deep interest which the Foundation has taken from the first in the welfare of people in the less-developed countries. Originally this was manifested through the fundamental studies and programmes in public health which its International Health Division undertook in many parts of the world Now it is equally manifest in the agricultural programme, which, beginning in Mexico, covers co-operative projects in Colombia, Chile, India and the Philippines, and the Foundation's researches on arthropod-borne virus diseases has at various times involved co-operative field stations in six different countries Supplementing these programmes and partly in support of them is the increased emphasis on training individuals from many countries for leadership in national and international development, and training is now a major sector of the Foundation's whole programme and is strongly oriented toward the less-developed countries Indeed, taking into account the increasing proportion of the Foundation's grants which seek to strengthen educational and research institutions overseas, education for leadership, particularly in the less-developed countries, could fairly be described as the dominant theme in the President's review; and it is presented with all the lucidity, cogency and balance which have marked the reviews of his distinguished predecessors

Mr Harrar notes first that the Foundation's fellowships are awarded to strengthen institutional faculties by enriching the experience of investigators and teachers, as well as for training younger individuals who plan careers in teaching and research Again, its travel awards have enabled many responsible leaders in all aspects of national planning to observe principles and practices in use elsewhere, and a considerable number of American scholars and scientists have worked for extended periods with colleagues in overseas institutions Further, individuals who have been associated with Foundation operating programmes or who have received training awards have been given assistance on their return to their parent institution to make them professionally more effective and to strengthen their departments and institutions Many grants, too, are made each year to institutions, departments and projects in the United States and abroad which seem of promise, the objective being to increase knowledge in its application for the benefit of mankind

In many countries the most urgent needs are for a steady rise in standards of living and for the broadening of scholastic, intellectual and creative opportunities; but in some, early priority must be given to improvements in sanitation, public health and medical care, and to increased food production as the basis of an adequate diet Until these requirements are satisfied, Mr Harrar points out, real progress in housing, transport, communications and other technologies is impossible scholarly activities and the creative arts are unlikely to flourish among sick or under-nourished people The need for more qualified persons to accept major responsibilities in government, education, science, technology, and economic and social development is manifest everywhere. Innate ability is not lacking, but opportunities for its full development are often grossly inadequate, and accordingly the most important single element in the progress of the less-developed or emerging States is leadership. Both the quality of training and the number trained are important, and these Mr Harrar fully recognizes are primarily a national responsibility, philanthropic and other foreign agencies can only help at critical points, particularly at the more advanced levels. Although most future leaders and investigators must necessarily receive their basic training at national institutions, and can only be sent overseas for training on a selective basis, it is for this reason that bodies like the Rockefeller Foundation are especially concerned with training for leadership

The urgent and growing demands being made on scientific and technological man-power and on professional man-power make it the more important that such resources should be used with skill and perception Here Mr. Harrar suggests that private foundations operating overseas have a unique opportunity to assist in creating patterns by which the limited numbers of highly trained individuals in less-developed countries can contribute most effectively to research and to the training of younger people If these leaders are properly situated, supported and encouraged, they can create islands of excellence which, with increasing numbers, may grow and coalesce into a firm base for genuine progress In view of the many opportunities for investment in excellence in the United States, the Rockefeller Foundation is increasingly selecting those which may ultimately pay substantial dividends both there and abroad, a significant proportion of the Foundation's grants to educational institutions in the United States are now in recognition of their part in training people from the less-advanced countries, and to assist the extension of various phases of institutional programmes in the United States into critical areas abroad

---

* The President's Review from the Rockefeller Foundation Annual Report 1960 Pp 96 (Rockefeller Foundation, 111 West 50th Street, New York, 1961)

In this belief that the greatest challenge to private foundations is their work for the benefit of mankind, Mr Harrar discusses further the importance of educational developments in the less-developed countries and the contribution of the Foundation's scheme of fellowships and training grants for study abroad These have been used to assist particularly promising or enterprising individuals, with the object of encouraging the development of growing points of excellence The Foundation's interest in programmes for the control of specific diseases has almost entirely given place to this type of development There is, however, one exception, namely, the virtually world-wide problem of malnutrition, and for the past twenty years the Foundation has been attacking this problem at what might be regarded as its source—inadequately developed agricultural practices Attention has also been given to the adaptation of available food supply to biological needs, and three grants during the current year—one to Harvard University for a co-operative project with the Medical School in Cali, Colombia, one to the National Institute of Nutrition in Mexico, and one to the Institute of Nutrition of Central America and Panama in Guatemala—are cited as contributions in the Foundation's continuing programme for improving theory and practice in nutrition

The problem of food supply and nutrition is, however, closely linked with that of population and its growth, and here for thirty years the Foundation has sought opportunities to advance knowledge of all aspects of the reproductive process, while latterly the psychological implications of the reproductive process and sociological study of the pattern of population growth have received attention This latter aspect has received particular attention from the Population Council, which has done a great deal to increase world knowledge of the population problem, and last year arranged with the Johns Hopkins School of Public Health that the School should add to its staff experts in various phases of the population question Some of their time will be spent at Johns Hopkins studying matters of basic theory and practical application, but an appropriate portion of their time will be available to the Population Council for field-work in co-operation with government health services responsible for planning more orderly changes in the size of population.

The Rockefeller Foundation has participated in initiating this new arrangement, which should increase the number of competent investigators of the difficult problem of how to change public attitude and practice in this field For the past five years, too, the Foundation has been exploring possible ways of increasing the supply of well-trained diplomats for the execution of foreign policy and the effective representation of the interests of the emerging countries' interests abroad The critical importance of this factor has been repeatedly demonstrated by the events of the past year, but in this field assistance in training well-qualified leaders is a far more complex problem and directly involves issues of national independence, prestige and pride

One method adopted by the Foundation originated from the request of the representative of a South Asian country for help in strengthening the library of his Ministry of Foreign Affairs, which was quite inadequate for present-day needs. Some twenty-five countries have now sought such assistance, which has been provided for twenty-one after discussion with the ambassador or a senior official of each country, while representatives of more than twenty countries took the initiative in requesting further aid and guidance in training their young diplomats In consequence, the Carnegie Endowment for International Peace formulated a programme for creating a corps of diplomats thoroughly conversant with the practices and procedures of modern international relations Under this programme, to which, since April 1959, the Rockefeller Foundation has contributed 525,000 dollars, sixteen Fellows nominated by the governments of fifteen newly independent countries have been sent to the School of International Affairs at Columbia University or the Geneva Graduate Institute of International Studies, a part time seminar for younger diplomatic officers in embassies in Washington has been conducted by members of the Johns Hopkins University School of Advanced International Studies, and a training programme arranged in New York for young representatives of missions to the United Nations

A training and study programme at a more advanced level, involving a year of intensive study, has also been arranged at Harvard University and, taken together, the two programmes, to which the Foundation has contributed 668,200 dollars, represent a carefully designed attempt to meet the urgent needs of countries which almost overnight must develop a structure of government that requires competent and qualified foreign service personnel No one would suggest that such measures alone will solve the whole problem Stability and security must await the slow process of educating whole nations in the difficult art of responsible government, but the Rockefeller Foundation is clearly making a valuable contribution to a vital element in the provision of leaders of understanding and imagination

There are other fields also in which the Rockefeller Foundation is seeking to meet these needs of the emerging and under-developed nations. Mr Harrar refers to its efforts in dealing with the language problems in Peru and Bolivia, and intellectual communication between Latin America and the United States and among the Latin American countries themselves, but one of the most interesting sections of his review is that in which he describes the growing interest of the Foundation in the agricultural development of Africa, and particularly its efforts to enable the existing agricultural institutions of Africa to provide well-rounded organic programmes of agricultural research During 1960 the Foundation appropriated funds for this purpose to four institutions of university-level and one college of technology, as well as making awards to several experimental stations in East Africa for research on cereal crops and for studies of livestock physiology. Thus, 41,300 dollars went to the University of Khartoum faculties of agriculture and veterinary science, and 75,000 dollars to the University College of Rhodesia and Nyasaland for intensive studies of micro-organisms and their capacity for fixing nitrogen and on the range and adaptability of native species of grasses and their capacity to provide optimum grazing conditions for cattle. Lovanium University, in the Congo, received 26,300 dollars for the purchase of X-ray equipment for the study of the mineral content of tropical soils and the influence of weathering on them. The Department of Agriculture at the University College of Ibadan, Nigeria, received 40,000 dollars to accelerate studies of production economics and of the marketing, preservation and storage of produce and for studies of grass management systems for Ndama cattle, while 42,750 dollars went to Kumasi College of Technology for teaching and research equipment for agricultural science. Grants to the East African Agricultural and Forestry Research Organization, the Kenya Department of Agriculture and the East African Veterinary Research Organization brought the Foundation's total contribution in this field in 1960 to 405,350 dollars.

This is only a fraction of the Foundation's appropriation of 6,713,314 dollars for programmes in agricultural sciences in 1960 out of a total appropriation of nearly 33 million dollars, and of this some 2·6 million dollars were for the operating programmes in this field. It compares with appropriations of 10·25 million dollars in medical and natural sciences, nearly 4·5 million dollars for the humanities and nearly 4 million dollars for the social sciences, but it is interesting to note something of the same pattern in the allocation of grants by the Nuffield Foundation described in its latest annual report. Grants allocated for the Commonwealth Overseas amounted to some £375,000, including £250,000 for the proposed medical school at the University College of Rhodesia and Nyasaland, and its fellowship and scholarship schemes of £226,000 from grants which totalled £2·26 millions during the year, of which nearly £90,000 was for scientific research and just over £300,000 for medical research, the total amount for the Commonwealth Overseas being £600,000. While the Nuffield Foundation is clearly not directing the same effort to agricultural science as the Rockefeller Foundation, both Foundations are manifestly placing their emphasis on the support and fostering of excellence.

There are, indeed, passages in Mr. Harrar's review to the Rockefeller Foundation which seem to overlook the importance of an educated democracy and the dangers which can attend the use of the media of mass communication by the demagogue in the more backward countries. By and large, however, the efforts of the Rockefeller Foundation to help the emergent nations to develop the type of leadership and trained men and women they need are soundly and imaginatively conceived, and well designed to achieve their purpose if only they are given reasonable time.

SURVEY OF ANTIBIOTIC LITERATURE

Antibiotica

Herkunft—Arten—Eigenschaften. Von Prof. T. Korzybski und Prof. W. Kurylowicz. Pp. xix+1105. (Jena: Gustav Fischer Verlag, 1961.) 130 D.M.

THIS book, first published in Warsaw in 1955, now appears in German after being brought up to date. Its object is to summarize in a systematic way the enormous amount of antibiotic literature which has appeared since the discovery of penicillin. The authors believe that it will help in the very difficult problem of quickly identifying an antibiotic met with in antibiotic research if it has already been described in the literature.

In the introduction, the authors point out that it is not possible yet to classify antibiotics from a chemical point of view as so many of the antibiotics described are of unknown chemical structure. Hence, they chose to classify antibiotics according to their sources. There are seven chapters dealing, in turn, with antibiotics from bacteria, Actinomycetes, Fungi Imperfecti, Basidiomycetes and Ascomycetes, lichens and algae, higher plants, and animal sources. The first three chapters are further subdivided, Chapters 1 and 3 on the basis of a sub-classification of the source, while in Chapter 2, which comprises more than half the book, the principal basis of subdivision is the type of antibiotic activity displayed.

Despite the fact that it is not possible to classify all antibiotics from a chemical point of view, there are a few clearly recognizable chemical groups and these are treated together by the authors. Thus Section C of Chapter 1, which deals with antibiotics produced by bacilli, contains a useful general discussion of polypeptide antibiotics, and the polypeptide antibiotics produced by Actinomycetes are dealt with in a section of Chapter 2. This chapter also includes a section dealing with the Macrolide group of antibiotics (Erythromycin, Magnamycin, etc.) and the antibiotics active against moulds are divided into the polyene antibiotics and others, and a brief general discussion of the polyene antibiotics is given.

From the narrow point of view of the identification of a particular antibiotic, a basic classification on, for example, extractability into various types of solvent might have been preferable to that adopted. But the authors have a rather broader purpose; they appear to have made satisfactory use of order wherever it exists, and they have probably produced as good and workable a classification as is possible at the present time.

The articles on individual antibiotics aim at giving the name and description of the source; a summary of culture media, methods of cultivation, isolation and purification; the physical and chemical properties; the antibiotic spectrum, the toxicity found in animal experiments, and the ultimate importance in medical research such as clinical application, if any. Naturally, many descriptions are not complete, either due to the absence of information in the literature or because statements in the literature are not sufficiently precise.

The preface is dated June 1960, and the latest reference appears to be dated September 1959. Allowing for the great amount of work that must have gone into the preparation of the book for the press, this appears to represent as small a time-lag as could be hoped for, so that the book may be considered satisfactorily up to date. Extensive tests have failed to reveal any omissions so that the book's coverage of its field appears to be complete

Besides the pages of contents, which list all antibiotics described by name, there are an author index, an index of antibiotic names and an index of sources With these aids, no reader should experience any difficulty in finding what he wants

I have read a number of individual articles dealing with antibotics and in every case the article was found to present a very satisfactory and accurate summary of the information available in the literature

The bibliographies are very good and wherever possible references are included to review articles and monographs which contain comprehensive bibliographies

Careful perusal of the book from all points of view, therefore, suggests that it is destined to become an important work in the field of antibiotic research The price will, unfortunately, probably prevent many individual research workers from buying it, but it is a book which should be included in any library which makes a serious attempt to cover antibiotic interests In such libraries it will almost certainly prove to be in constant demand B K KELLY

TRAITÉ DE ZOOLOGIE

Traité de Zoologie

Anatomie, Systématique, Biologie Publié sous la Direction de Pierre-P. Grassé Tome 5, Fascicule 1 Annélides, Myzostomides, Sipunculiens, Echiuriens, Priapuliens, Endoproctes, Phoronidiens Pp viii + 1116 + 5 planches Fascicule 2 Bryozoaires, Brachiopodes, Chétognathes, Pogonophores, Mollusques (Géneralités, Aplacophores, Polyplacophores, Monoplacphores, Bivalves) Pp 1168 + 5 planches (Paris Masson et Cie, 1960) Broché 180 NF , cartonné 190 NF each

THE present welcome volume, in two fascicules, deals with a number of separate and not all closely related groups of the lower invertebrates as indicated in the titles Both fascicules contain almost precisely the same number of pages Each has a short list of errata, a detailed and excellent index and a full, expanded table of contents, which appears at the end They are both very well illustrated, each with 5 coloured plates and Fasc 1 with 904 and Fasc 2 with 954 text figures While many of the illustrations are borrowed but redrawn, a remarkably high proportion are original and they reach a very high standard, adding much to the usefulness and attractiveness of the volume

Apart from the editor, Prof Pierre-P Grassé, ten authors contribute to Fasc 1, two of whom, one from Brussels and one from Algiers, come from outside France, and all are experts in their own fields The majority of the text figures are line blocks and 18 have one or in some cases two colours introduced, and this is a commendable practice since it aids easier and quicker interpretation , Fig 857 in the present copy has the colour out of register, a point that is noted because the others are so exact Twenty-one figures are in half-tone The text of the chapter on the Phoronidea finished on p 1053 and is followed by a number of addenda which amplify or bring up to date points in the preceding sections and then by the index and table of contents Curiously, these pages are numbered MLV-MCXVI and the figures I-XXIX, but in Fasc 2 the pagination and numbering of text figures carry on with p 1054 and Fig 876 as if the pages numbered in Roman numerals did not exist In some places, for example, p 34 keferSteinii, p 120 dumerilii, etc , the double 'i' is employed instead of the now generally accepted single 'i' and on p. 994 the former name is misspelled Kleferstein Two forms, *Histriobdella* and *Branchiobdella*, the names of which suggest leeches, with which, *inter alia*, they have been placed and the systematic position of which has been subject to discussion, are here regarded as highly modified and as a parasitic polychæte and a parasitic oligochæte respectively Another anomalous form, *Acanthobdella*, some of the characters of which suggest Oligochæte affinities, has now been placed in the Acanthobdelliformes, a new order of the Hirudinea An anecdote well known in Great Britain will now be lost sight of as it has been shown, p 846, that *Golfingia macIntoshii* is a synonym of *G vulgare*.

Ten authors are also concerned with Fasc 2 and of these three come from outside France, two from Copenhagen and one from Leningrad In this fascicule there are only 4 text figures with colour introduced, but there are 63 half-tone blocks and of these 8 occupy the whole page and are of wash drawings, each showing about a dozen species The rest of the figures are in line block The first class to be treated in the longest chapter is the Bryozoa, falling into the two sub-classes proposed by G J Allman in 1856, the Phylactolaemata, all freshwater, and the Gymnolaemata, marine The latter were divided into three orders Cyclostomata, Cheilostomata and Ctenostomata by G Busk in 1852 and this grouping was accepted for more than seventy years In 1926 F Borg showed that the Cyclostomata (his Stenolaemata) were more widely separated from the other two than these were from one another, and E Marcus in 1938 placed them as sub-orders of the Eurystomata This classification, with its corollaries to include fossil forms, has been adopted in the present work It is rather strange to find Allman's monograph on fresh-water Polyzoa appearing under the bibliography of the Gymnolaemata

About half-way through the volume is a most interesting chapter on the Pogonophora In 1914 M Caullery described an enigmatic tubicolous worm-like creature with numerous tentacles, hence Pogonophora (πωγων, a beard), collected by the *Siboga* Expedition The material was not very well preserved and so a completely satisfactory account could not be given and indeed it was suggested that this animal called by its discoverer *Siboglinum weberi*, might only be the anterior part of an animal since no trace of an alimentary canal was found It was considered that the creature might be allied to the Enteropneusta and so M Caullery contributed a chapter on it in volume XI of the *Traité*, where indeed it belongs, in 1948 Since then, and particularly by Prof A V Ivanoff of Leningrad, a great deal of additional information has been furnished and now 11 genera with 43 species have been described from better-preserved material The editor has fortunately got Prof Ivanoff to contribute the chapter on the Pogonophora It is the first account and survey available to the general zoologist It provides a very complete account of the anatomy, histology and embryonic development, and in addition to the ordinary text figures mostly original, there are three coloured plates These depict the animals in three dimensions It is clear that they are deuterostomes with a single cœlomic sac in the protosome, which sends canals into the tentacles, a pair of cœlomic sacs in the mesosome and another pair in the metasome. It is concluded that they are related to the Stomatochorda and particularly to the enteropneusts. This connexion with the early Chordata together with the absence of an alimentary canal render them an important and intriguing class.

The next class calling for comment is the Monoplacophora, a name given by N. Odhner in 1940 to a group of Palæozoic Mollusca until then grouped with the Patellacea. In 1957, however, H. Lemche described a living form, *Neopilina galatheae*, referable to the group which had been collected five years previously by the *Galathea* Expedition from west of Costa Rica at a depth of 3,570 metres. Afterwards, H. Lemche and a colleague, K. G. Wingstrand of Copenhagen, gave a full account of it in the *Galathea Reports*. The editor of the volume, Pierre-P. Grassé, got these two authors to provide an account, which he translated, illustrated by a number of new figures, so that again we have the first general account of a most remarkable animal from the original describers. The well-developed cœlomic cavities are described as consisting of three pairs—the pericardial pair, the body pair which lie dorsally and are extensive, and the gonads. The apparent metamerism of a number of organs (muscles, nerves, gills, blood vessels, nephridia and gonads) is well marked and considered by the authors to be comparable with that in Annelida and Arthropoda. These points raise interesting problems concerning the relationships and derivation of the primitive molluscs. While the chapter was in the press another mollusc, for the present referred to the same genus *N. ewingi*, was reported (Clarke, A. H., and Menzies, R. J., *Science*, 1959), and although little information regarding it is available it seems to offer certain divergences from *N. galatheae* which will have to be taken into account before coming to definite conclusions on the problems above mentioned.

Here, then, is another addition to this widely used text-book that is indispensable to every zoological laboratory. It reaches the high standard in both text and illustration set by its predecessors and is indeed a noteworthy and commendable volume.

C. H. O'Donoghue

POLYMER CHEMISTRY

An Introduction to the Organic Chemistry of High Polymers

By Prof. Carl S. Marvel. Pp. viii + 82. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 36*s*. net.

THIS book consists of notes originally assembled for use in connexion with the Humble Lectures in Science, delivered by Prof. Marvel in 1956. It is intended for those just starting research in polymer chemistry.

Most of the introductory texts at present available in polymer chemistry attempt to be reasonably comprehensive in their choice of topics: this one is strictly limited to the organic chemistry of high polymers. Neither the physical chemistry of polymers and their solutions nor physicochemical methods of studying polymers are considered. After a very brief description of methods for the characterization of polymers, the author proceeds to a systematic consideration of various types of condensation polymerization. Both free radical and ionic methods of addition polymerization are then discussed, followed by chapters on co-polymerization and di-ene polymerization. A short account of reactions of polymers concludes the book.

As is only to be expected in a book of this size, individual topics are not dealt with in much detail. There are a number of occasions, however, where the discussion is so brief as to lack clarity. Particular examples are the section on the mechanism of free radical addition polymerization and the introduction to the section on co-polymerization.

The most serious limitation of the book is that it is already five years out of date. It is a pity that so little attempt seems to have been made to include work done after 1956. Because of the rate at which polymer chemistry is advancing, this leads to some important omissions. For example, topics which are omitted or receive only the briefest mention include stereospecific polymerization, polyaldehydes, polycarbonates, polymer stability and degradation, radiation methods, and new methods of anionic polymerization. Quite apart from their importance, these developments in the forefront of the subject are those most likely to arouse the enthusiasm of a beginner, which is surely one purpose any book of this kind should serve.

There are few trivial misprints. More serious is the appearance of pentavalent carbon on pages 47 and 48, unhappily in a place where the unwary reader might be misled into thinking that Friedel–Crafts-type catalysts used in cationic polymerization are covalently bound to the polymer chain. On page 47 is the statement that in every case of co-catalysis in the initiation of cationic polymerization the real initiator is believed to be a proton. This neglects the important cases where there is good evidence that carbonium ions derived from the solvent are chain initiators.

The book is, in general, attractively printed and strongly bound. At a cost of fivepence a page, however, it must be one of the most expensive chemistry books available.

QUANTITATIVE BIOLOGY

Blood and other Body Fluids

Analysis and compilation by Philip L. Altman. Edited by Dorothy S. Dittmer. (Biological Handbooks.) Pp. xvii + 540. (Washington, D.C.: Federation of American Societies for Experimental Biology, 1961.) 10 dollars.

NUMERICAL information is becoming of ever-increasing importance in all branches of biology. While physicists, chemists and engineers started long ago to compile handbooks of data, the collection of biological figures is of relatively recent date. The first major systematic effort in this direction were the *Tabulae Biologicae* which were initiated in the 1930's. Some ten years ago the United States National Academy of Sciences and the United States National Research Council began to sponsor a series of biological handbooks which has so far led to the publication of ten volumes. Some deal with blood, nutrition, metabolism, general biology, respiration and circulation, and five others with various aspects of toxicology and pharmacology (acute toxicity, antibiotics, insecticides, tranquillizers and fungicides). The present volume is based on these earlier handbooks and is the first to appear under the general direction of the Committee of Biological Handbooks of the Federation of American Societies for Experimental Biology The material is presented in the form of tables, graphs, diagrams, nomograms and line charts Three hundred and eighty investigators have taken part in the compilation and much trouble has been taken to obtain accuracy, to eliminate misprints and to exclude material of questionable validity Apart from blood, fields covered include urine, lymph, hæmolymph, cerebrospinal fluid, body water, various secretions of the digestive tract, reproductive secretions, milk, sweat, sebum and the fluids of the ear and eye Among the species, man occupies the first place, but the information extends to numerous other vertebrate and invertebrate organisms

While the data of physical and chemical reference books are usually constants which have been measured with a known accuracy, biological data are, as a rule, not so definable. they are not constants and their scatter is in many cases not sufficiently known The figures given in the book are therefore bound to be of varying degrees of reliability, but this difficulty has been effectively met by detailed references to the sources of information In fact the references given may well prove to be one of the most valuable features of a very useful mine of factual information

H A KREBS

A NEW STANDARD WORK ON COCOA

Cocoa

By D H Urquhart Second edition (Tropical Agriculture Series) Pp xxv + 293 + 129 plates (London Longmans, Green and Co , Ltd , 1961) 40*s* net

THIS book was originally published in 1955 and two additional impressions were issued in 1955 and 1956 The new (second) edition attempts to bring the subject-matter up to date It contains one entirely new chapter (on manuring) and several of the chapters of the first edition have been combined in the second The total number of pages has thus been increased from 230 to 293 The book is one of a series on tropical agriculture of which five volumes have already been published. The author of *Cocoa* was formerly director of agriculture of Ghana, West Africa, and adviser in cocoa-growing to Messrs Cadbury Bros , Ltd , Bournville, Birmingham, England

The book includes all the detailed information needed by practical cocoa farmers, as well as students and agricultural extension workers Its usefulness is greatly enhanced by the excellent illustrations and the tables of data. Much progress has been made in the cocoa industry since the first edition of this book appeared in 1955, particularly in the control of pests and diseases of the cocoa tree, and the detailed specification of the atmospheric and soil environment necessary for maximum production of cocoa Thus, in the chapters concerning soils and manuring, the results of researches carried out in recent years in Ghana by the late C F Charter and in Belgian Congo by M V Homes have been incorporated into the new edition The establishment, maintenance and costings of the cocoa plantation, the rehabilitation of the derelict and unremunerative plantation, and the preparation and grading of the crop for market, receive detailed consideration in no less than seven chapters and nine appendixes, spanning a total of 159 pages or 50 per cent of the total number of pages comprising the book, thus stressing the essentially practical outlook That Urquhart's book is providing a much-needed standard work on cocoa and one which is a worthy successor to the classical works on the subject written by C J J Van Hall and by J H Hart, which have long been out of print, is indicated by the fact that the first edition and its two impressions were exhausted after only five years had elapsed The need for a Spanish version has already become manifest, and the task of translation has been undertaken by the Inter-American Institute of Agricultural Sciences at Turrialba, Costa Rica Publication of the Spanish edition is expected shortly, it should add to the increasing demand for the book by making it available to cocoa growers in tropical America

LONDON LIBRARIES

The Libraries of London

Edited by Raymond Irwin and Ronald Staveley Second, revised edition Pp 332 (London The Library Association, 1961) 36*s*

THE first edition of this work, published in 1949, was based on lectures delivered during a course at the School of Librarianship and Archives, University College, London, and was intended to supplement but not replace R A Rye's *Students Guide to the Libraries of London* That work has long been out of print and even the first edition of *The Libraries of London* is now largely out of date Accordingly, the new edition attempts to present a much fuller picture of the library resources of London All the chapters have been carefully revised and most have been largely re-written, there is a new chapter on the University College Library, and separate chapters on the University of London Library, on the British Library of Political and Economic Science, while the other university libraries are described in a separate chapter Additional chapters deal with the music libraries, the ecclesiastical and theological libraries, the industrial libraries, technical and professional libraries and those of the learned societies, and of the London County Council, while that on the Public Record Office is omitted Apart from the London Library, no attempt is made to describe the commercial and subscription libraries, and likewise there is no reference to the libraries associated with the offices of the great national newspapers

The individual chapters are the work of different authors, all authorities in their field, but what is gained in authority is sometimes offset in part by lack of balance, and diversity of scale and treatment That on the Science Museum Library, by the late H T. Pledge, is frankly episodical, and besides its historical or descriptive lacunæ, it has scant reference to future developments The Patent Office Library is more adequately covered, but there are some surprising omissions in the chapter on Government Departmental libraries, while that on industrial libraries is scarcely of greater value than as a reminder of the existence of such libraries , it is content to list and describe those of the British Aluminium Company, the Cement and Concrete Association, and the British Paper and Board Industry Research Association Nevertheless, used with imagination, this book, produced in accordance with the high standards which are customary with the Library Association, forms a most useful and convenient guide to the bibliographical resources of London

R BRIGHTMAN

Sensation and Perception

A History of the Philosophy of Perception By D W Hamlyn (International Library of Philosophy and Scientific Method) Pp xi+210 (London Routledge and Kegan Paul, Ltd , New York The Humanities Press, 1961) 25*s* net

THERE is something very refreshing about this book It deals with a complex theme without reducing the reader to fatigue and his patience to zero Broadly, the author takes as his 'matter' the trio—sensation, perception, judgment—and subjects them to a careful historical analysis In a word, we are told how these concepts have evolved with time, not forgetting that ideas need verbal expression for them to come into being However, the absence of such terms is not proof positive that the 'germ' was not alive in the mind of philosophers, at any given epoch, or even perhaps at some previous period

We begin with the classical figures, followed by a lively discussion of Hellenistic thought (Incidentally, the heading to Chapter 2 on page 31 looks very odd with this adjective spelt with one 'l') Next come chapters on the seventeenth century, rationalists, empiricists, Kant, Hegel, idealism, nineteenth-century sensationalism, the reaction, the twentieth century, conclusion There are an excellent bibliography and an adequate index

The connexion with *Gestalt* theory is well handled Perception, given that the whole is more than the sum of its parts, needs no learning "because it is innately determined" Perception, if passive, tends to sensation; if active, to judgment The former is unsatisfactory in various ways, especially to the scientist, who uses the second almost subconsciously. What must be avoided, as Wittgenstein remarked, is the introduction into this study of one's own experiences In the pre-perceptual sense at least, there is no private language

The style is pleasant and lucid fewer italics would have made it still more agreeable without any loss of emphasis F I. G RAWLINS

Analytical Chemistry of the Rare Earths

By Dr. R C Vickery (International Series of Monographs on Analytical Chemistry, Vol 3) Pp viii+137 (London and New York Pergamon Press, 1961.) 40*s* net

THE rare earths, as defined by the author of this invaluable little volume, comprise the lanthanon series to lutetium with the addition of yttrium and scandium

The analytical examination of mixtures of these elements has been rendered far less time-consuming in recent years by the application of the newer technique of X-ray fluorescence analysis Radioassay following neutron irradiation now permits the determination of millimicrogram quantities, and controlled ion-exchange experiments have enabled the chemist to separate the individual rare earths in a very pure form All these modern methods are described lucidly in this monograph, which also contains the most detailed description of the more classical, but still eulogized, absorption spectrum technique for the detection and estimation of these intractable elements Conventional emission spectrography is not neglected by the author, for despite the complexity of the spectra given by these elements, there are occasions where the arc, or preferably the spark technique, can give the most useful quantitative information A table is given of the main persistent lines of the rare-earths emission spectra, and various internal standard line-pairs are also presented in tabular form for specified concentration ranges

Polarographic methods as applied to the unique cases of samarium, europium and ytterbium are described briefly in the appendix

The earlier chapters deal with the more classical methods of gravimetric and volumetric analyses, and here the student will find a wealth of information on chemical separational procedures The analysis of ores, the separation of calcium and iron, the usages of selective organic reagents such as Beck's pyrocatechol, complications attending the Group III hydroxide precipitations, are all described with much attention to laboratory detail Although quantitative methods for the determination of the rare earths are now almost wholly instrumental, the uses of oxalate, iodate, bismuthate and complexan reagents are well worthy of recapitulation. In retrospect, we join with the author in expressing unqualified admiration of the skill, patience and ingenuity shown by the early chemical research workers who isolated, albeit in crude form, the first rare-earth elements

This monograph has much to commend it to the academic student, but for the rare-earth chemist it is most certainly an essential acquisition and will prove a valuable laboratory companion D T LEWIS

Paper Electrophoresis

A Review of Methods and Results By L P Ribeiro, E Mitidieri, and O R Affonso. Pp. xii+463 (Amsterdam Elsevier Publishing Company, London D Van Nostrand Company, Ltd , 1961) 72*s*

THIS book by Ribeiro, Mitidieri and Affonso represents a welcome and thorough classification of the already voluminous literature on ionography There is a wealth of references, 3,200, some of which have been published only in the more esoteric medical journals

The first part of the book includes chapters on the theory, methods and apparatus The theoretical chapter is written with great clarity and will be very useful to beginners in this field Even Ohm's law is included and there is a useful example on the results of Joule's effect "When high voltages are used there will naturally be an increase in current causing an elevation in temperature which may be so great as to ignite the paper "

In the subsequent part of the book on applications the emphasis is on proteins, but there are also chapters on hormones, vitamins, carbohydrates, nucleic acids, amino-acids and peptides, a sketchy chapter on inorganic substances, one on immunochemistry and one on other applications which deals with topics as diverse as amines, dyes and venoms

The large bibliography means that the treatment afforded individual references varies considerably throughout the book, ranging from minute practical detail to just the reference itself The book has few printing and translation errors and the diagrams are well produced Two points might, however, be mentioned on page 211 the structural formula given for the sugar unit after oxidation with periodic acid appears to be that for an α-diketone rather than for a di-aldehyde as suggested in the text, and for greater clarity the cyclohexane rings which appear in some of the formulæ throughout the book might, where appropriate, be amended to aromatic rings

The book will undoubtedly be a valuable asset to biochemists, chemists and clinicians particularly as there are more than three hundred references per ounce G V F SEAMAN

A MICROBIOLOGICAL EXAMINATION OF SOME CARBONACEOUS CHONDRITES

By Dr GEORGE CLAUS
New York University, Medical Center, New York
AND
Prof. BARTHOLOMEW NAGY
Department of Chemistry, Fordham University, New York

MICROSCOPIC-sized particles, resembling fossil algae, were found to be present in relatively large quantities in the Orgueil and Ivuna carbonaceous meteorites No such particles were found in two ordinary stony meteorites, namely, in Holbrook and in Bruderheim

There are nineteen known carbonaceous chondrites, all of which were observed to fall Orgueil fell in southern France in 1864, Ivuna in Central Africa in 1938, Mighei in Russia in 1889, and Murray in the United States in 1950 Carbonaceous chondrites contain water and a few per cent of organic matter

Wiik[1] has shown that carbonaceous chondrites may contain as much as 20 per cent water On the basis of his hydrogen isotope work, Boato[2] concluded that a large portion of this water in Orgueil and Ivuna is of extraterrestrial origin Carbonaceous chondrites have thin fusion crusts Mueller[3] and others found that after the development of the indigenous, hydrous-mineral components, the interior of these meteorites was not subjected to high temperatures The interiors of some of the carbonaceous meteorites apparently have not been heated to temperatures higher than approximately 200° C

Berzelius[4] and Wohler[5] extracted organic matter from carbonaceous chondrites. Berthelot[6] obtained saturated hydrocarbons from a sample of Orgueil In more recent years, Mueller extracted the Cold Bokkeveld meteorite and obtained organic matter which had high oxygen, nitrogen and sulphur content Calvin[7] suggested that a compound resembling cytosine might be present in Orgueil, and Briggs[8] presented analyses which may indicate the presence of purines Nagy, Meinschein and Hennessy[9] analysed hydrocarbons from Orgueil with a mass spectrometer and observed certain spectral features which resembled those of biogenic hydrocarbon mixtures

Urey and Craig[10] concluded that the carbonaceous meteorites are typical members of the high iron group chondrites These investigators reported that serpentine-type minerals and magnetite are present in carbonaceous chondrites Kvasha[11] suggested that chlorite, a hydrous layer-lattice silicate, is a mineral component in Staroye Boriskino.

Five carbonaceous chondrite samples were examined during this work. One Orgueil sample (*A*), Ivuna and Mighei, were obtained from the American Museum of Natural History in New York, and another sample of Orgueil (*B*) was received from the U S National Museum in Washington, D C The sample of the Murray meteorite was obtained from the Institute of Meteoritics, University of New Mexico, Albuquerque, New Mexico One of the two non-carbonaceous chondrites, Bruderheim, was received from the Department of Geology, University of Alberta, Edmonton, Alberta, and the other, Holbrook, was received from the American Museum of Natural History

Grains of the meteorite samples were crumbled in water or in glycerol on glass slides. A microscopic examination of the two Orgueil samples and of Ivuna revealed the presence of particles which were dissimilar in morphology to any known mineral form The 'organized elements' resembled, but were not identical to, the morphology of certain species of algae which live in water (The aquatic algae are capable of producing hydrocarbons[12] comparable with those previously found in Orgueil[9]) One form of the organized elements was morphologically dissimilar to any known terrestrial organism The organized elements did not show birefringence in polarized light, but they did show fluorescence (yellow) in ultraviolet light (Fig 1). A few specimens of microbiological contaminants (common, airborne bacteria, algae, etc) were present in the carbonaceous as well as in the non-carbonaceous meteorites Organized elements were abundant in the Orgueil and Ivuna carbonaceous chondrites but were absent in Holbrook and in Bruderheim

Somewhat similar but poorly defined particles were found in Murray and Mighei. Their lack of structure precluded identification with the organized elements from Orgueil and Ivuna (see Table 1)

Five types of organized elements have thus far been observed

(1) Small, circular forms (Fig. 1), surrounded by double walls which showed thickening and occasional sculpturing with protuberances Their diameter varied between 4 and 10μ and they appeared yellowish-green in transmitted light. The interior of the organized elements appeared to be either homogeneous or it was granulated

(2) The second type (Figs 2 and 3) resembled the first one; however, the surfaces of these organized elements were covered with spines, with other appendages or with a furrow The appendages usually appeared to be tubular in shape, and occasionally they penetrated through the walls. The diameter of the appendages varied between 0 5 and 2μ, and that

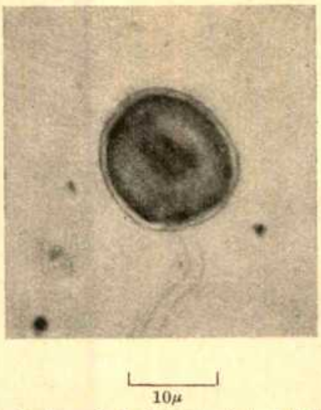

Fig. 2. Organized element of type 2 in the Orgueil meteorite

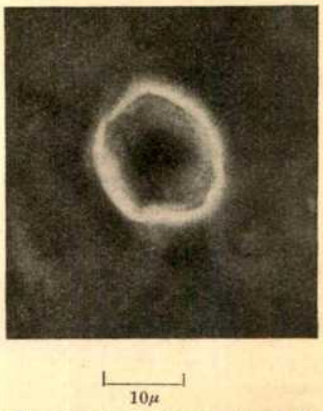

Fig. 3. Organized element of type 2 as seen under the phase-contrast microscope. Note internal structure of the organized element

of the organized elements was between 8 and 30μ. Solid appendages had club-like structures on their distal ends. Spines were arranged in pairs around the appendages. The furrow started at the single appendage on the apex of the organized elements.

(3) The third type of the organized elements had shapes like shields. They had no appendages. Their walls showed marked thickening and sculpturing; their average diameter was approximately 15μ.

(4) Cylindrical forms were seen which had thick walls and finely sculptured wall surfaces. Their length was approximately 20μ, their width was 10–12μ.

(5) An apparently hexagonal form was also observed (Fig. 4). This organized element may contain, however, 10–12 surfaces. Three of the surfaces were considerably thicker than the others and they served as the bases of the three, thick, tubular protrusions. The organized element seemed to be surrounded by a structureless halo, which was interrupted only by some matter that was protruding from two of the appendages. There were three vacuole-like and irregularly shaped bodies in the interior of the organized element.

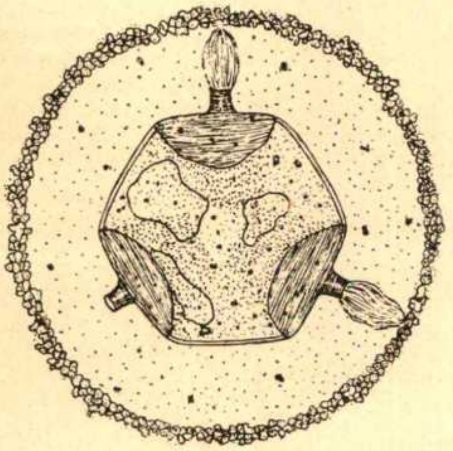

Fig. 4. Sketch of organized element of type 5. (Drawing is used because the original forms were not suitable for taking photographs)

The Orgueil meteorite samples contained each of the five organized element types. Only the first three types were present in Ivuna. Types 1 and 2 were by far the most abundant in both Orgueil and Ivuna.

There were other morphological features which should be mentioned. Several of the organized elements appeared to undergo 'cell-divisions'. Constrictions occurred in the middle portions of the elongated bodies in one form of this phenomenon, proceeding toward the interior and suggesting the formation of two 'daughter' bodies (Fig. 5). Several organized elements showed distortion and rupture of the walls. Often the interior appeared to be spilling out through the fractured walls.

Attempts were made to identify the chemical components of the organized elements with biological staining techniques; chlorzink-iodine, toluidine blue, methylene blue, Janus green *B*, Feulgen, Gridley, acid-carmine, periodic acid–Schiff, hæmatoxylin eosine and ninhydrin gave colour reactions. The reliability and the significance of the colour reactions in the organized elements are not known. It is interesting to note, however, that diffuse nuclear-staining material was found in the organized elements (Fig. 6).

From these morphological, optical and staining results we have interpreted the organized elements as possible remnants of organisms.

Although the origin of these organized elements cannot be answered at this time, indications of their

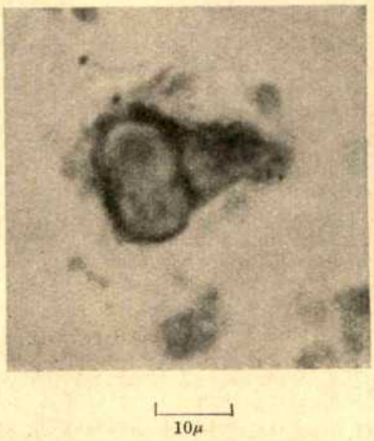

Fig. 5. Organized element of type 2 resembling 'cell division'

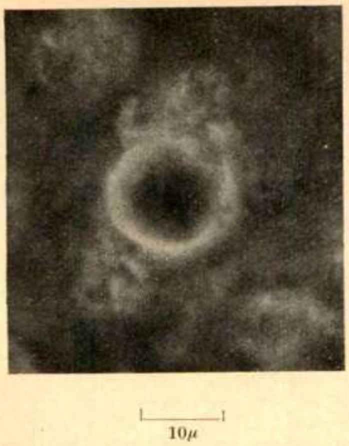

Fig. 6. Organized element of type 1 after Feulgen staining; note indications of diffuse nuclear material

origin may be summarized in the following observations:

(1) The high concentrations of the organized elements in Orgueil and in Ivuna could have developed only in an environment where moisture was continuously present for a prolonged period of time; yet the meteorite samples were kept in dry museum storage and would have disintegrated if subjected to an aqueous medium. Furthermore, they were outdoors for only a few hours after they had fallen. There are only traces, if any, of capillary water retained in the meteorites.

(2) The organized elements, types 1–4, resemble those species of Dinoflagellates or Chrysomonads which live only in water (in the sea or in lakes, and do not occur in the soils).

(3) Types 1–4 appear to be similar to but not identical with known terrestrial species. The fifth type of the organized elements is entirely dissimilar in its morphology to known terrestrial form.

(4) Terrestrial organisms resembling types 1–4 of the organized elements develop cysts under unfavourable conditions (such as a drying or dry environment). Only two or three of the organized elements in Orgueil and in Ivuna showed structures resembling cysts.

(5) The fact that the same types of organized elements were present in both Orgueil samples which fell in the temperate climate of southern France, and in Ivuna, which fell seventy-four years after Orgueil in an arid, tropical region of Central Africa, renders unlikely contamination with morphologically identical, locally derived, micro-organisms.

The morphological similarities are of interest in the light of unpublished results of one of the authors[13] which indicate a chemical similarity between Orgueil and Ivuna.

We are of the opinion that these observations suggest that the organized elements may be microfossils indigenous to the meteorite.

We would like to express our appreciation to Prof. Douglas J. Hennessy, of Fordham University, and to Dr. Warren G. Meinschein, of the Esso Research and Engineering Co., for their constructive criticisms. Dr. Meinschein originally proposed also a palinological examination of meteorites. We would also like to thank those persons with whom these results have been discussed: Prof. Harold C. Urey, of the University of California; Dr. Brian Mason, of the American Museum of Natural History; Dr. Jack Green, of North American Aviation, Inc.; Dr. C. Mervin Palmer, U.S. Public Health Service; Profs. Currier E. McEwan, Maxwell Schubert, Norman Cooper and Alan J. Johnson, of New York University Medical Center; Prof. Henrik P. deBoom, University of Pretoria, South Africa; Dr. Bela J. Cholnoky, Council for Scientific and Industrial Research, Water Research, Pretoria; and Prof. Alexander Wolsky, Fordham University. Profs. Urey, Wolsky, Hennessy, Schubert and Johnson and Dr. Meinschein read the manuscript and offered valuable advice regarding this presentation. The meteorite samples were provided by Drs. Brian Mason, E. P. Henderson, Lincoln LaPaz and Prof. R. E. Folinsbee.

BRADYKININ

By DR. G. P. LEWIS

National Institute for Medical Research, Mill Hill, London, N.W.7

BRADYKININ is a polypeptide discovered in 1949 by Rocha e Silva, Beraldo and Rosenfeld[1], who coined the name 'bradykinin' (slow-moving) because, when acting on the guinea pig intestine, it caused a delayed and slow contraction. They showed that it is formed by the action of certain enzymes, such as those in some snake venoms and trypsin, on plasma globulins. 'Kallikrein' is the name given to another group of enzymes which occur in the body and which act on the plasma globulins to form bradykinin-like activity. Much of the earlier work on these enzymes was that of Frey, Kraut and Werle, and was reviewed by them in 1950 [2]. A vasodepressor substance was shown to be present in urine[3], in pancreas[4], in blood[5] and in saliva[6], although it was not realized at that time that this vasodepressor substance was an enzyme, acting by the formation of a vasodilator polypeptide. The active principle in all these fluids was called 'kallikrein'. However, the kallikrein obtained from these various sources is not the same enzyme. Blood kallikrein, which is different from that in glands, behaves like the proteolytic enzyme plasmin[7] and is inhibited by proteolytic inhibitors[8]. The glandular kallikrein does not behave like a proteolytic

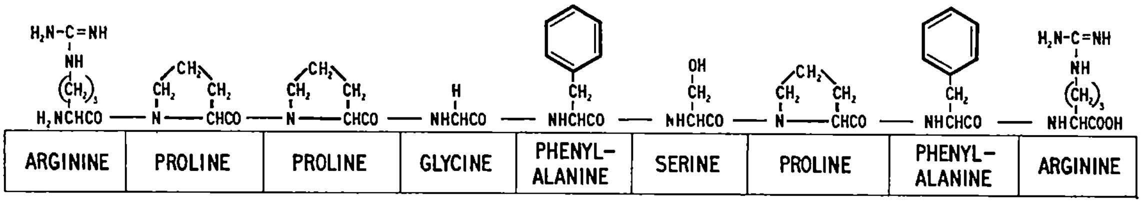

Fig 1 Structure of bradykinin

enzyme[9]—it does not hydrolyse substrates, like casein, nor is it inhibited by proteolytic inhibitors However, the kallikrein of the salivary gland hydrolyses certain synthetic esters, but not the corresponding amides[10] This gives support to the theory of Rocha e Silva and Hamburg[11,12] that bradykinin is formed by an esteratic action

Trypsin and plasmin are both proteolytic and esteratic enzymes—it may be that some of the kallikreins, particularly glandular kallikrein, are not proteolytic enzymes at all, but esterases It is possible that the two classes of enzymes—the slow-kinin-forming enzyme and the quick-kinin-forming enzyme described by Lewis[9] are the proteolytic and esteratic enzymes respectively Whatever the truth may be, it is certain that there are several different kinds of enzymes which act on the plasma globulins to form bradykinin, or at least peptides, which are closely related to bradykinin

It is not certain whether the peptide formed by these different enzymes is the same in each case and therefore the name 'plasma kinin' has been suggested to cover all the peptides formed from plasma proteins in this way For example, the name plasma kinin may be applied to the principles which are formed in blood under various conditions, such as when plasma is diluted[13] or when plasma comes into contact with a glass surface[14] Presumably these physical actions result in activation of one of the plasma-kinin-forming enzymes which are normally present in blood as inactive precursors Although the exact structure of all the peptides formed by these various enzymes is not known, we do know the amino-acid sequence of one plasma kinin—bradykinin After attempts by Andrade, Diniz and Rocha e Silva[15,16], who obtained bradykinin of high activity, it was finally isolated[17], and synthesized[18,19] From an incubated mixture of crystalline trypsin and pseudoglobulin Elliott, Horton and I isolated bradykinin using mainly the technique of elution chromatography on carboxy-methylcellulose The peptide was eluted from the columns using a salt gradient at constant *p*H The volatile buffer ammonium acetate was used as eluant so that the samples could be evaporated, thus avoiding contamination with salt

The pure peptide obtained in this way contains five amino-acids in the following molar proportions serine 1, glycine 1, phenylalanine 2, arginine 2 and proline 3 giving nine amino-acid residues or a nonapeptide

These are present in bradykinin in the sequence shown in Fig 1 (ref 20) The natural and synthetic products were found to be identical[21-23]

The main pharmacological actions of bradykinin are smooth muscle stimulation, vasodilatation, increase in capillary permeability, accumulation and migration of leucocytes and production of pain

Most smooth muscle preparations are stimulated by bradykinin even in minute amounts The rat uterus is contracted by 0 1 ngm /ml (10^{-10}) and the guinea pig ileum by 1 0 ngm /ml (10^{-9}), while the rat duodenum is relaxed by bradykinin 0 1 ngm /ml (10^{-10}) Some smooth muscle preparations like the rabbit jejunum and rat colon, which show spontaneous activity, are first relaxed and then contracted by bradykinin Bradykinin causes bronchoconstriction in the guinea pig[24], although it has no effect on the bronchioles in the dog[25] In non-asthmatic patients large doses of bradykinin, given as an aerosol, occasionally cause constriction of the bronchioles, asthmatics are more sensitive[26], but it seems doubtful that bradykinin is concerned specifically in asthma

Bradykinin is one of the most active vasodilator substances known In the cat hind limb bradykinin is as active as acetylcholine[27]. On the flow of blood in the human forearm bradykinin was found to be a more active vasodilator than histamine, acetylcholine, isoprenaline and 5-hydroxytryptamine[28] In some of these experiments as little as 0 1 μgm bradykinin injected into the brachial artery caused a strong vasodilatation in the whole forearm

It has been known for some years that crude mixtures containing bradykinin cause an increase in capillary permeability[29] and pain[14] With the availability of the pure peptide it was shown that pure bradykinin possesses both of these actions on local application[27]

In addition, bradykinin causes accumulation and migration of leucocytes[30] This effect, however, is produced only by relatively large doses of bradykinin (1–100 μgm /ml) and in such doses other peptides affect leucocytes in the same way

Bradykinin thus causes vasodilatation, increased capillary permeability, production of pain and accumulation and migration of leucocytes These are the cardinal signs of the early stages of the inflammatory response It therefore seems likely that bradykinin plays the part of a mediator in this reaction. Menkin[31,32] originated the view that specific polypeptides may be responsible for the inflammatory response It is possible that bradykinin is one of a group of peptides which account for this reaction as postulated by Menkin There is no direct evidence yet that bradykinin is formed during the inflammatory reaction, however, it is possible, as suggested by Hilton and Lewis[33], that bradykinin or perhaps the enzyme which forms bradykinin may correspond to the *H*-colloid of T H Lewis[34] and of Krogh[35], which together with *H*-substance (presumably histamine) accounts for many of the reactions to local tissue injury No specific antagonist of bradykinin is yet available in order to test such a hypothesis by inhibiting or preventing inflammation It has been claimed that phenylbutazone is an antagonist of bradykinin[36] As phenylbutazone is known to be a potent anti-inflammatory agent this would provide good evidence that bradykinin plays a major part in inflammation However, the action of phenylbutazone is not specifically to antagonize bradykinin, and many other drugs are partially antagonized by the large doses of phenylbutazone required (Lewis, G. P , unpublished results). Another anti-inflammatory agent—aspirin—specifically antagonizes the bronchoconstriction caused by bradykinin in guinea pigs[34] However, here again this cannot be taken as evidence of the role of bradykinin in inflammation. as aspirin does not antagonize those actions of bradykinin which would be involved in inflammatory reactions (Lewis, G. P., unpublished results).

Although there is no direct evidence of the part bradykinin may play in the reactions to local injury, there is evidence of the part it takes as a physiological mediator of functional vasodilatation, as shown by the experiments of Hilton and Lewis[33,37–39] on perfused salivary glands In these experiment it was found that during activation of the glands an enzyme, probably salivary kallikrein, escaped from the secretory cells into the tissue space and that this enzyme formed bradykinin, or at least a plasma kinin, when it came into contact with the plasma globulins When the gland cells are activated, the enzyme thus escapes both into the duct to appear in the secretion and into the interstitial space of the gland around the blood vessels to form the vasodilator polypeptide As kallikrein appears in many glandular secretions, it follows that all these glands have the plasma-kinin-forming mechanism which might therefore be the mechanism in such glands for producing functional vasodilatation In this way—by producing an increased blood flow in the gland—bradykinin supplies the gland with the fluid required during secretion. It might not only be in glands themselves that bradykinin has such a role; in tissues which contain an abundance of glands, intestine and skin, for example, it may also account for periglandular vasodilatation. For example, in the intestine it is possible that the activation of intestinal glands leads to bradykinin formation which would bring about the vasodilatation required during the assimilation of foodstuffs

In skin, Fox and Hilton[40] have found that human sweat contains a plasma-kinin-forming enzyme and by analogy with the salivary glands have concluded that bradykinin formation accounts for the vasodilatation in the glands during secretory activity In the case of sweat glands bradykinin plays an additional part. As the sweat glands are in such close proximity to each other in the skin it seems likely that when the glands are activated, during body heating, the bradykinin formation which occurs accounts for the vasodilatation in the whole skin This is the conclusion Fox and Hilton reached from their experiments on increased forearm blood-flow during body heating In thus providing extra fluid in the increased flow of blood to form further sweat to be secreted and evaporated, bradykinin plays a part in the regulation of body heat

The theory that bradykinin is the mediator of functional vasodilatation in glands and glandular tissue has been challenged on two points

First, Terroux, Sekelj and Burgen[41] claimed to have dissociated glandular activity and vasodilatation in the salivary glands As a measure of glandular activity they used oxygen uptake However, whether oxygen uptake reflects the glandular activity quantitatively is doubtful, as these authors themselves suggest that part of the metabolism in the secreting gland occurs through anaerobic glycolysis Their experiments show that small doses of atropine reduced the increased uptake of oxygen in parallel with secretion when the gland was activated by stimulation of the chorda tympani nerve, but did not affect vasodilatation in the gland This problem has been examined extensively by Hilton and Lewis[38], and we have shown that after atropine, even in doses larger than those generally used by Terroux, Sekelj and Burgen, nerve stimulation still produced an output of plasma-kinin-forming enzyme As the enzyme comes from the secretory cells, it is evident that although overt secretion is prevented, some of the biochemical processes associated with glandular activity are still stimulated. Therefore. the lack of parallelism between oxygen uptake and vasodilatation in the partially atropinized gland is not a relevant argument against the view that bradykinin is responsible for functional vasodilatation

Secondly, Schachter[42] observed that guinea pig saliva did not act on guinea pig serum to form bradykinin and concluded that functional vasodilatation was not the result of bradykinin formation However, Schachter also observed that the guinea pig serum used in these experiments did not form bradykinin with the saliva from cat, rat and man, but that guinea pig saliva did form a plasma kinin when incubated with the serum of other species It seems, therefore, that it is not that guinea pig saliva does not contain the plasma-kinin-forming enzyme but that under the conditions of this particular test the serum did not react with salivary kallikrein from any species. Plasma and serum are known to contain a complex mixture of enzymes, inhibitors and activators (see ref 43) and it may well be that in order to produce bradykinin from guinea pig serum by the action of salivary kallikrein *in vitro*, special treatment of the serum proteins is necessary

Functional vasodilatation is a feature of glands which act intermittently, like the salivary glands, and it requires a mechanism which produces a large increase in blood flow of rapid onset and short duration It might well be that in glands which are continuously active over relatively long periods of time, such as mammary and endocrine glands, no such functional vasodilatation occurs This would explain the absence of plasma-kinin-forming enzyme from the secretions of such glands as ovary, thyroid and prostate[44]

The part played by bradykinin in functional vasodilatation in glands and glandular tissues and its possible role in inflammation depend on two factors which limit the area in which the reaction goes on, that is, factors which localize the reactions First, it seems likely that the formation, the action and the destruction of bradykinin go on in the interstitial fluid In a gland, for example, this would mean that when the gland is activated the enzyme escapes from the secretory cells into the interstitial fluid; there it acts on the globulins and forms bradykinin The peptide dilates the blood vessels and is eliminated via the lymph. Hilton and Lewis[37] provided evidence that this actually occurs in the salivary glands and that under normal conditions it is not necessary for the peptide or the enzyme which forms it to enter the blood stream Thus, this physiological reaction would be physically limited to the interstitial space of a gland Secondly, there is an efficient mechanism in the body for destroying excess bradykinin In blood, and probably in interstitial fluid, there is an enzyme which rapidly destroys bradykinin and thus controls the action of bradykinin Without this mechanism bradykinin formation in the blood stream would result in generalized peripheral vasodilatation and vascular collapse This is, in fact, what might happen in certain cases of shock The reactions of certain proteins, such as antigen and antibody in the blood stream, may activate the plasma-kinin-forming system Bradykinin or a plasma kinin would then be formed in the blood stream and if it were associated with a reduction in the bradykinin-destroying activity of blood, it would result in vascular collapse and shock

However, there is as yet no evidence to indicate that bradykinin plays any part in generalized reactions All the evidence that we have suggests that bradykinin acts in local reactions, first, as the physiological mediator of functional vasodilatation and, secondly, as a mediator of the inflammatory response In such local phenomena bradykinin might well be classified as a local tissue hormone

FOOD PROCESSING IN RELATION TO HEALTH

THE final session of Section I (Physiology and Biochemistry) of the British Association meeting held at Norwich on September 6 was devoted to "Food Processing in Relation to Health", but the four papers read did not—and indeed could not in the short time available—cover the complex nature of the problems implied by the title Nor were the full implications of the subject raised in discussion, an omission which may indicate that the audience were aware that many of the questions they might have asked cannot, in the present state of knowledge, be answered No contribution was included in the programme on the nutritive effects of food processing, a subject on which all too little information exists, but one on which it would have been useful, and perhaps salutary, to have had a summary Nevertheless, some other aspects of food processing entered into the other papers, and if all are viewed together an otherwise fairly complete picture emerges Miss D F. Hollingsworth (London) described trends over eighty years in food consumption Prof John Yudkin (London) discussed dietary fat, and Dr Magnus Pyke (Menstrie, Clackmannanshire) dietary protein in relation to health Finally, Dr J R Nicholls (London) reviewed the need for food preservation by means of additives and the precautions taken to ensure safety

As a background to any consideration of trends in food consumption, it is necessary to study trends in food supplies In the United Kingdom such statistics are readily available, for the years immediately before 1939 and for each year since the outbreak of war, in reports of the former Ministry of Food and the present Ministry of Agriculture, Fisheries and Food on food consumption-levels, now published annually in the *Board of Trade Journal* Earlier estimates, which are not fully comparable with present ones, but which serve to indicate trends, were made by a committee set up by the British Association in 1880 to estimate the apportionment of the national income between different foods and services, with particular reference to foods, for the years 1909–13 by a committee of the Royal Society as a basis for studying the adequacy of national food supplies in the First World War, and for the years 1924–28, independently, by Sir Alfred Flux and Sir Albert Feavearyear Examination of all these data shows that in eighty years the character of British food supplies has changed remarkably. In 1880, 55 per cent of the energy value of food supply was derived from grain and potatoes compared with 34 per cent immediately before the War, 43 per cent in the 'forties and 31 per cent in 1959 The marked changes in the other direction have been for proportions of the energy value derived from animal products, which increased from 21 per cent in 1880 to 27 per cent in 1959, from fats and oils, which increased from 5 per cent in 1880 to 17 per cent in 1959, and from sugar, which increased from 13 per cent in 1880 to 17 per cent in 1959 Over a longer time, increasing sugar consumption is perhaps the most remarkable of all, consumption in Britain having increased five-fold in the past century and twenty-five times over two hundred years Comparison of these trends with corresponding ones for the United States suggests that the proportions from fats and oils and sugar are unlikely to increase further, but that, if the standard of living continues to rise and manual work to decrease, the proportion from grain and potatoes may fall further with a corresponding increase in that from animal products Such a general trend towards more food of animal and less of vegetable origin (with the possible exceptions of sugar, fruits and green and other non-starchy vegetables) is to be found in all affluent societies, and its desired nature has been recognized since the writing of the Proverb, "Better is a dinner of herbs where love is, than a stalled ox and hatred therewith"

The nutritional pattern of the national food supply in Britain, after war-time and post-war changes, became fairly stable by 1956 For all nutrients evaluated, the national diet in 1959 was of greater nutritional value than before the War Its energy value was 5 per cent above the pre-war estimate and had scarcely changed since rationing ended in 1954 The most marked changes, compared with pre-war estimates, were for calcium and thiamine, which stood at 66 and 38 per cent, respectively, above the pre-war levels in 1947, and have remained almost unchanged since About one-third of the increase in calcium came from increased milk supplies and the rest from the addition of *creta præparata* to flour The restoration of thiamine to flour was largely responsible for the maintenance of the supply of this vitamin, and the restoration of iron and nicotinic acid to flour was the main cause of the increases in these nutrients Animal protein and vitamin A also showed substantial increases Increased consumption of dairy products was the main reason for the rise in animal protein The rise in vitamin A came in almost equal amounts from milk and its products, liver, vegetables containing carotene, and margarine fortified with vitamin A, which more than offset reduced butter consumption

Within this general trend towards a diet containing more foods of animal and less of vegetable origin there has been another, a striking trend towards the increased consumption during the past few years of the so-called 'convenience' foods, in which the manufacturer has relieved the housewife of much of the labour of preparation

Supplies of canned meat and canned vegetables are nearly three times those of the pre-war years and well above those available in the early 'fifties Supplies of canned fruit and home-produced canned soups were in 1959 more than twice as great as in 1953, while the supply of canned fish was three times as great Consumption of unsweetened evaporated milk (which acts as a substitute for cream) is steadily increasing, but that of sweetened whole and skim milk is declining

In the past five years the production of dried soups has doubled Since 1954 there has been intense competition in the breakfast-cereal market which has included the introduction of sugared cereals Biscuit production has doubled in the past ten years Custard powder is becoming less popular, but sales of table jellies, ice-cream and soft drinks are increasing 'Instant coffee' has rapidly gained ground, and 'instant tea has appeared Another development has been in frozen foods In the past ten years consumption of frozen vegetables (almost entirely peas) has increased about eight-fold, and since 1953 consumption of frozen fish, not all of which is purchased in the frozen state, has quadrupled A recent innovation is the sale of frozen partly prepared main dishes, such as chicken pie, and another even more recent is the production of dehydrated ready meals The growth of the self-service shop and supermarket has probably led to a greater revolution in the presentation of meat products to the public than of other groceries or provisions

According to the National Food Survey, nearly one-fifth of domestic food expenditure in Britain in 1959 was devoted to cooked and canned meats, other meat products, cooked and canned fish, quick-frozen legumes, canned vegetables, canned fruit, fruit juices, factory-produced cakes, pastries, biscuits and puddings, quick-cooking cereals, canned and dehydrated soups, and recent trends suggest that such expenditure will rise

In considering dietary fat in relation to health, Prof Yudkin said that under war-time and post-war rationing there were claims that fat consumption was too low and that this was responsible for dry skins, dull hair, a feeling of lassitude and an increase in the incidence of infection The claim to-day is that we eat too much fat and this results in a variety of illnesses, the most important being obesity and coronary heart disease. His view is that there was no evidence that we suffered from inadequate consumption of fat during rationing and scarcely any evidence that we are suffering from excessive consumption to-day The quantity of fat needed for human health is unknown

Obesity, an important medical problem, is due to eating more food than is needed Prof Yudkin made two points on this first, that our increasingly sedentary lives have decreased food needs, but many people are not eating less, and, secondly, that before the introduction of arable farming our prehistoric ancestors must have lived mainly on protein and fat, the outstanding dietary change occurring at the beginning of civilization being an increase in carbohydrate consumption In the past two centuries an additional change has been the remarkable increase in the consumption of sugar with a reduction in other forms of carbohydrate For these reasons he recommended that the best way to prevent or cure obesity is to eat much less carbohydrate and not to worry about fat intake

Turning next to consideration of coronary heart disease, Prof Yudkin said that there seems to be no doubt that coronary thrombosis has become more common in the past twenty years in the developed countries such as Great Britain, and that it is far less common in countries and communities where the diet contains little fat In spite of increasing research into the subject, the main evidence relating fat consumption and coronary thrombosis is still epidemiological and no direct evidence linking the two has been produced On the whole, populations with low consumption of fat have little coronary thrombosis But these are also populations with low standards of living, whose diets differ in ways other than in their fat content, and whose lives differ in ways other than diet. There are only one or two investigations in which the comparisons are of groups with similar diets but differing modes of life, or with different diets but similar modes of life, these investigations do not support the theory that dietary fat is the single factor causing coronary disease The investigations which compare the increased incidence of the disease with the changing consumption of fat equally do not show a close relationship The present evidence fits best the suggestion that coronary thrombosis is caused by a number of factors, these include heredity, lack of physical activity, smoking, mental stress and overweight Prof Yudkin concluded that there may well be other factors, and that one of these may be an excess or deficiency of one or more nutrients, such as fat in general or some kinds of fats in particular His main conclusion was, however, a plea for more research

Dr Pyke's theme was the simple one that a proper understanding of the chemistry of food and the physiological requirements of people makes it possible to arrange that food processing shall be entirely beneficial to consumers He illustrated his theme by a description of modern work on the assessment, in terms of amino-acids, of both the composition of proteins and human protein requirements He spoke of early work on the improvement in health brought about by increased consumption by children of liquid milk and, more recently, of dried skim milk This led to the modern approach in developing countries of studying the available protein foods, assessing their amino-acid content, mixing and producing a palatable product designed to meet the amino-acid needs of the children for whom it is intended He gave as a concrete example the production of 'Incaparina' by Dr Scrimshaw and his colleagues in Guatemala from maize, sorghum, cotton-seed, yeast, calcium carbonate, leaf meal and vitamin A This can be made into a palatable gruel acceptable by children suffering from protein malnutrition Its effectiveness was demonstrated by pictures of an affected child before and after treatment

Dr Nicholls spoke of man's need since prehistoric times to preserve and store foods so as to find the means of avoiding both glut and famine By tradition, salt, sugar, vinegar and other materials have been used to preserve foods In present urban life, other additions are necessary to prevent damage during transport and storage, and to produce for the housewife more attractive, more convenient foods of better keeping quality. Such additives must be of real practical value and must not impair significantly nutritive properties nor involve a health hazard. Dr Nicholls described the ways of testing and controlling the use of additives not normally accepted as food ingredients, including the work of the Advisory Committee on Poisonous Substances used in Agriculture and Food Storage, the Food Standards Committee, various scientific bodies and the chemical and food manufacturers' laboratories

D F HOLLINGSWORTH

SPEECH

A SYMPOSIUM on speech was held on September 5 during the British Association meeting in Norwich under the joint auspices of Sections I and J (Physiology and Psychology) The chair was taken by Prof O L Zangwill (Cambridge), who pointed out that this was a near-centenary occasion In 1868, the British Association met at Norwich and held a famous discussion on speech to which Broca and Hughlings Jackson were the main contributors In addition to commemorating this occasion, it was hoped that the symposium would serve to draw together recent lines of work on problems of speech and illustrate changing conceptions in the study of aphasia

Neurology of Speech

The discussion was opened by Sir Russell Brain (London), who began by paying tribute to Hughlings Jackson's remarkable contribution to the neurology of language When Jackson addressed the British Association at Norwich at the early age of thirty-three he had already evolved the main ideas which were later to transform our thinking about aphasia. In particular, he saw clearly the need for fuller understanding of the physiology of speech and in this respect physiology had lagged behind anatomy. Whereas the work of Broca and his successors threw much light on the areas of the brain involved in language, it had failed to clarify its nature as a physiological activity In Sir Russell's view, progress in the study of aphasia depends above all on our gaining more adequate insight into the physiological basis of normal speech.

Sir Russell proceeded to outline three lines of approach which might serve in some measure to bridge the gap between the anatomy and psychology of language First, important clues might be derived from genetic study In particular, we need to know how the infant's perception of his own voice monitors his speech production. In the adult, it is known that delayed speech 'playback' markedly dislocates the output of speech[1], and it is not extravagant to suppose that certain types of speech disorder owe their origin to derangement of aural 'feedback'. There is consequently a need for fuller analysis of the basic mechanisms involved in the acquisition and regulation of speech

Secondly, Sir Russell laid stress on phonetic studies and their implications for the physiology of speech Modern technical methods have made possible very precise analysis of the physical properties of speech sounds and have thrown a good deal of light on the characteristics of sound patterns on which intelligibility depends Yet we still know little of the central mechanisms which govern the recognition of speech sounds and which enable constant meanings to be attached to what we hear Context, it would seem, is an important consideration Thus, what particular consonant is heard has been shown to depend in many instances on the vowel by which it is followed[2] In the case of word-meaning, context is of even greater importance and raises in acute form the whole problem of serial order in central nervous activity[3]. In view of these considerations, Sir Russell was concerned to stress the need for concepts which do adequate justice to the flexibility of language. In particular, he proposed that the concept of the 'schema', originally put forward by Head and Holmes[4] in regard to the appreciation of posture, might find fruitful application to the physiological organization of speech[5].

Thirdly, Sir Russell paid tribute to the growth of communications theory. He approved of the use of statistical method in the analysis of speech, and of the view that the brain is to be regarded as an instrument for the estimation of probabilities. Indeed, what he had called the 'schema' might perhaps be defined as the physiological mechanism which enables the individual to gamble on the probability that a particular sound pattern is to be invested with a particular meaning. He added that probability theory is now being successfully applied to the analysis of vocabulary and its reduction in aphasia.

Techniques in the Study of Aphasia

Prof. R. C. Oldfield (Oxford) was mainly concerned with the development of techniques for the analysis of specific derangements of speech. He pointed out that whereas the clinical examination of dysphasic patients has changed little since the time of Hughlings Jackson, there has been some advance in methods designed to study particular facets of the disorder. For example, Head's tests[6] were modelled on quantitative physiological procedures and were intended to assess particular derangements of symbolic function. Unfortunately, Head's theoretical views had not found general acceptance and his tests are nowadays seldom used *in toto*. Weisenburg and McBride[7] developed some more standardized tests of intellectual function, but in view of the variability of performance in aphasia it is doubtful whether their use has led to significant advance. In general, Prof. Oldfield saw little purpose in studying aphasic cases in all their bewildering variety; better, he counselled, stick to purely linguistic issues and concentrate research effort on a narrow front.

Among new methods of particular promise, Prof. Oldfield singled out the work of Penfield and his associates[8] on the electrical stimulation of the exposed human brain cortex. As is well known, stimulation within the so-called 'speech areas' reproduces many of the clinical symptoms of aphasia, among them speech arrest, misnaming, distortions and ellisions, and wrong use of words (paraphasia). It is noteworthy, moreover, that the use of this technique has failed to sustain the classical distinction between 'sensory' and 'motor' speech zones set up on the basis of clinical study. Prof. Oldfield also directed attention to the recent use of intracarotid injection of sodium amytal[9] as a means of establishing hemisphere dominance, that is, the hemisphere in which speech is located. As with cortical stimulation, transient and reversible dysphasia may be produced. Such methods, Prof. Oldfield suggested, have obvious possibilities for the experimental analysis of disordered speech.

An account of some psychological work on nominal defects and related problems was then given. As Prof. Oldfield pointed out, naming an object involves more than the mere association between symbol and referent, and disorders of naming cannot be viewed in terms of the failure of specific associative links. It is necessary, for example, to consider redundancies within the total system within which we search in seeking a particular name. More generally, Prof. Oldfield urged that statistical study of the products of disordered speech is well worth undertaking, and its arduousness is nowadays much reduced by the availability of tape recorders and electronic computers. Such study, Prof. Oldfield suggested, might well model itself on the methods employed by Yule[10] and Zipf[11] in the statistical study of normal vocabulary. Preliminary examples of the application of quantitative methods to aphasia were described[12].

In conclusion, Prof. Oldfield once again laid emphasis on the need to select limited problems and to develop techniques appropriate to their study. Although clinical issues are often dramatic, it is not always the most interesting problems that lend themselves to scientific attack.

Why we have Two Ears

The third speaker was Prof. Colin Cherry (London), who dealt with problems in the general field of speech perception. He began by directing attention to axial symmetry in bodily structure and its significance for biological adaptation. In particular, the possession of two ears is important not only for directional listening but also for effecting maximal separation of sound sources and hence optimal discrimination of speech in a noisy environment. Prof. Cherry was therefore particularly concerned to determine the features which enable the brain to infer 'what goes with what' and thereby to create unified and meaningful auditory percepts (*Gestalten*).

An important light is thrown on speech perception by consideration of the facts of binaural fusion. In the case of tones of high frequency, the half wavelength of sound is less than the inter-aural separation, and here fusion appears to depend on an 'averaging process' which extracts the fluctuating envelopes of the sounds and rejects the high-frequency steady tones[13]. This may be expected greatly to extend the range of frequencies from which stable *Gestalten* can be built. Prof. Cherry further laid stress on the role of head rotation in producing time-differences at the two ears and thereby facilitating the discrimination of speech. As he rightly pointed out, the sense of hearing appears to be closely related to the sense of balance, and posture and head adjustments are clearly of great importance in exploring the acoustic world.

Prof. Cherry then touched briefly on the relations between hearing and speech. As he has shown, an individual can listen to and repeat a spoken message virtually concurrently ('shadowing') and it is noteworthy that even stammerers can often perform this task without appreciable handicap[14]. This might suggest not only that speech and hearing form a single integrated activity but also that impediments of speech may be due to faulty aural monitoring rather than to executive disability. Indeed, such findings do much to reinforce Sir Russell Brain's plea that greater attention should be devoted to the 'feedback' mechanism in the regulation of normal speech.

The problem of binaural speech perception was next considered, with special reference to dichotic listening. Some years ago, it was shown that if two different messages are fed simultaneously through headphones, one to each ear, the subject can 'shadow' either message at will but is rendered almost totally unaware of what is reaching the 'neglected' ear[15]. In real life, however, we seldom listen to competing sources of information in so simple a manner. More commonly, the listener is assailed by a barrage of voices which have different mutual time-relations at the two ears and various other small differences. In separating them, it is necessary to assume a kind of inductive inference based in part on past experience. Can this be studied?

As a first step, Prof. Cherry described an experiment still in progress in which the subject wears headphones and listens to a message recorded on a special tape recorder. This enables various time intervals to be introduced between right and left headphones and thus causes the fused sound image to move from side to side in the listener's head. A second voice which may likewise be caused to move is then introduced. With the first voice set at a given position, the second is moved to right or left of it randomly by various amounts, and at each setting the subject guesses whether the shifted voice is to the right or left of the fixed voice. Although the statistics of the guesses show some measure of uncertainty, the task can in general be performed. On the other hand, if sounds provided by random noise generators are substituted for the voices, it becomes almost impossible to accomplish; indeed the listener hears two noises as a single fused sound[16]. The next step in the experiment is to proceed either by removing clues from the voices (for example, by removing larynx pitches) or by adding clues to the random noise sources (for example, by introducing a sharp resonance); in each case the measure of uncertainty shows the extent to which the clues in question are utilized. Although the results are not yet complete, Prof. Cherry held out good hopes that the technique would prove powerful in enabling us to specify "what there is about human voices that enables them to be separated so efficiently".

It will be seen, then, that Prof. Cherry was concerned to isolate the factors involved in the segregation of complex auditory experiences. This analysis, he submitted, must be set out in the mathematics of statistical inference. It must be supposed that the brain is able to carry out a kind of 'correlational analysis' which enables it to identify certain invariant clues under an infinite variety of uncertain transformations. These clues are to be regarded as statistical invariants, and correlations (or hierarchies of correlations) are required to assess them. So far, he had been concerned only with first-order, short-term correlation functions[17], which allow a start to be made in describing the logic of certain perceptual operations. These computations, he suggested, which involve operations of short-term storage, coincidence detection and averaging of sensory data, may well be 'natural' to the central nervous system. The ultimate test of such an approach is, however, physiological, and Prof. Cherry concluded by asking physiologists whether, when considering the brain as a computer, it had been looked at from this point of view.

In his closing remarks, Prof. O. L. Zangwill contrasted the approach to speech evidenced by the contributors to this symposium with that of their predecessors ninety-three years ago.

First, he said, it is plain that much less weight is attached nowadays to consideration of structure. Unlike Broca, Sir Russell Brain had brought along no colourful charts to demonstrate the cerebral seat of speech and evidently did not regard anatomical issues as of prime importance. Although the problem of cerebral localization of course remains, it now seems doubtful whether clinico-pathological study alone can throw important light on the mechanism of speech. Indeed, neurologists appear to be turning increasingly to neurophysiology, experimental psychology and communications theory to help in the elucidation of clinical phenomena. In this field at least, pathology has proved itself a disappointing guide to our understanding of normal function.

Secondly, Prof. Zangwill directed attention to some striking changes in our general conception of the speech processes. In Broca's day, it was customary to break down speech into a multiplicity of elements, sensory and motor, and to suppose that each of these possessed determinate cerebral localization. Even Hughlings Jackson had not been wholly free from this tendency to over-simplify. To-day, it would seem, our approach is decidedly anti-analytical; no one had spoken of sensations, images or related products of introspective abstraction. Indeed, the emphasis had been almost wholly on higher-order organization and on the brain mechanisms conceived to underlie it. This had been particularly well brought out by Prof. Cherry in his valuable studies of binaural integration and the perception of speech.

Lastly, Prof. Zangwill commented on the astonishing extent to which statistical thinking now dominates our approach to problems of language. Statistics were unknown to Hughlings Jackson, but it would appear that his successors can ill afford to disregard them. No longer can speech be envisaged in terms of reflexes and habits of an essentially particulate nature, and no longer can disorders of speech be viewed in terms of the loss of particular reactions or classes of reaction. As Prof. Oldfield so well showed, analysis of the products of disordered speech cannot be satisfactorily undertaken without recourse to considerations of probability theory. Although information theory may give difficulty to the non-mathematical, clearly it must be accepted if our knowledge of speech is to progress.

OBITUARIES

Prof. H. V. A. Briscoe

HENRY VINCENT AIRD BRISCOE died in London after a short illness on September 24, 1961, his seventy-third birthday. He was professor of inorganic chemistry in the University of London at the Imperial College of Science and Technology during 1932–54 and thereafter professor emeritus and Fellow of the Imperial College. Briscoe was educated first at the City of London School and then the Royal College of Science, which at the time was on the point of being incorporated within the framework of the Imperial College. He graduated with honours in chemistry and then first assisted Sir Edward Thorpe in a revision of his *Dictionary*. Although he was still a junior member of the teaching staff of the Imperial College, during the First World War he was engaged in responsible and secret work (which similarly occupied much of his time during the Second World War) and later took charge of the Organic Chemistry Department at Sir John Cass College before being appointed in 1921 to the chair of inorganic and physical chemistry at Armstrong College (now King's College), Newcastle upon Tyne. He became head of the Chemistry Department in 1925 and later served as dean of the Faculty of Science in the University of Durham. Six years following his return to the Imperial College, on the retirement of Prof. J. C. Philip, he became director of the Laboratories of Inorganic and Physical Chemistry, a position he held until his retirement.

In addition to his academic positions, Briscoe had many outside interests: among other things he was the first director of the Northern Coke Research Committee's laboratory, president of the Research Association of British Paint, Colour and Varnish Manufacturers, visitor and manager of the Royal Institution of Great Britain and Ireland, vice-president of the Royal Institute of Chemistry, as well as being a member of Council and officer of the Chemical Society, and chairman of a local section of the Society of Chemical Industry. After the Second World War he was also greatly concerned with the improvement of the supply of laboratory technicians in university work and was chairman of the Imperial College Technician Training Committee, of the similar University of London Committee and of the National Joint Committee on the Recruitment and Training of Science Laboratory Technicians.

Briscoe's scientific publications cover a wide range of interests. Although his first publication in 1912 with P. W. Robertson was on the migration of the *para*-halogen atom in phenols, he afterwards moved into the inorganic and physical area. Among his earlier works were precise atomic weight determinations of vanadium, tin, thallium, boron and bromine. He considered himself a disciple of T. W. Richards and was similarly devoted to rigorous purification and the development of new methods, such as those for handling volatile hydrolysable halides. He was also aware of the possibility of the variation in isotopic ratios of materials of different geological origin, and for his studies on boron developed a flotation method for the measurement of comparative densities of boron trichloride which gave values to within about $\pm 2 \times 10^{-6}$ unit. This density method, which was typical of Briscoe's experimental skills and ingenuity, was also applied to examine heavy water and he was among the first in Great Britain to be concerned with the use of deuterium and later oxygen-18 as tracers in exchange reactions. Briscoe also made contributions to the chemistry of rhenium oxides, halides and sulphides, and of selenium.

Throughout his career, Briscoe was much concerned with more applied aspects of chemistry and made many contributions to the knowledge of coke, paints and drying oils, on which he was an authority, purity of water, insect pests in foodstuffs, etc. During the 1930's he became very interested in the silicosis problem and hazardous industrial dusts and devised methods for collection and analysis of dust samples. For this work he was awarded the Consolidated Goldfields of South Africa Medal by the Institution of Mining and Metallurgy. Inspired by a lecture given by Langmuir at the College, and anticipating current interest by many years, he also worked with Sebba on the reduction of evaporation from water surfaces through the use of monolayers of cetyl alcohol.

Briscoe will be remembered by his colleagues and students for his approachability and kindly manner. He is survived by his wife and a son and daughter—both members of the medical profession.

G. WILKINSON

Prof. Carl Hermann

PROF. CARL HERMANN, director of the Crystallographic Institute at the University of Marburg, died unexpectedly in his sleep on September 12 at the age of sixty-three. He was a pupil of Max Born and a fellow research student with Werner Heisenberg, at Göttingen. Later he became a lecturer at Stuttgart, where he and Paul Ewald initiated the *Strukturberichte* which (with its successor *Structure Reports*) gives a detailed abstract of every known crystal structure determination, and which is a valued work of reference in every modern scientific library. He also developed, with Prof. C. Mauguin, a systematic nomenclature (now known as the Hermann–Mauguin notation) for the 230 space groups, from which the symmetry can be derived at a glance, and he travelled widely in the early 1930's, gathering material for the two volumes of the *Internationale Tabellen zur Bestimmung von Kristallstrukturen.*

Hermann and his wife Eva were guests in my home at the time when the National Socialist party doubled its strength in the General Election of June 1932, which later brought Hitler to power, and I can well remember their dismay, for they realized even then what would follow. Later, Carl Hermann refused to conform to the political conditions imposed on academic staff and he took a position as physicist at the I.G. Farbenwerke at Ludwigshafen, where he continued crystallographic research of high quality on the nature of chemical bonds and on symmetry in n-dimensional space. He and his wife were imprisoned throughout much of the Second World War for their increasing activities in hiding and helping innumerable Jews to escape from the terrors of Nazi persecution. Only his eminence as a scientist and the intervention of his friends saved him from the carrying out of a death sentence, but these years left their mark on him.

In 1947 he was appointed to the new chair of crystallography in the University of Marburg and he threw himself with great energy into the teaching of the subject and into the building-up of an active research school But he also gave much of his time to the work of the Society of Friends, of which he and his wife were members, and to efforts to promote international understanding His presence at conferences was the more valued because of his great gift for languages, if a new language interested him, he learnt it

The statement put out by the Rector and Senate of the University of Marburg says of him. "Carl Hermann was a man of absolute integrity, and of kindness to others which had no limit For many years he was a member of the Disciplinary Court of the University and it was always he who tried to understand and to excuse the defendant . "

He is not likely to be forgotten, for he has left many friends KATHLEEN LONSDALE

Prof. E. Taylor Jones

THE death on September 29 of Prof Edward Taylor Jones at the age of eighty-eight will have been noted with deep regret by the many who benefited from his unique qualities both as a teacher and research supervisor His own education followed a pattern that was familiar at the turn of the century. His studies at University College, Bangor, and the University of Berlin were followed by a time as professor of physics at Bangor and a long period as professor of natural philosophy in the University of Glasgow, a period prolonged by the advent of war in 1939 His interests throughout his life extended over a wide field of physics and he seemed, in fact, to be equally interested in physics and in electrical engineering Thus, his earlier researches were in the classical field of electromagnetism with special reference to the mechanism of oscillatory devices such as the singing arc, the induction coil, the Tesla coil, and the magneto

Research into the behaviour of the induction coil may well have led to his very early attack on a variety of problems in electron diffraction. He was greatly excited by the elegant de Broglie approach to wave mechanics and soon followed the lead given by G. P Thomson at the University of Aberdeen in his famous work on electron diffraction This was a notable switch in interest and could have resulted in a greater volume of original work but for the limitations of means and research students of that time Nevertheless, on average he supervised the work of some five research students throughout his active career I myself realized, as one of his research students, that Taylor Jones made many fruitful suggestions while never stultifying the initiative of members of his team He preferred to play the part of adviser and in this he gave freely of his store of knowledge

He will doubtless be remembered by most as an inspired teacher of the very large ordinary classes These seemed to fascinate him He took great pains to make his courses lively and even at times hilarious, obviously believing that above all interest must be generated His extremely expert clowning in some of his demonstrations made it inconceivable that an understanding of the fundamentals should be beyond any student In spite of this unique approach to his ordinary classes there was considerable discipline in his handling of classes of more than two hundred students With the advanced classes he was content to follow more orthodox patterns of instruction He must have roused within many a life-long interest in physics by his vivid proof that science could be fun

Prof Taylor Jones had many publications to his credit and the list of these shows his versatility and widely ranging interests Physics made startling advances throughout his life and he was excited by many of them He did not confine his research interests closely and he never looked with favour on team-work In this respect he belonged with the individualists of his earlier period Those who knew him as a friend realized how fully he enjoyed his life spent in physical science. S. C. CURRAN

Dr. Madeline Kerr

IT was with deep regret that the colleagues and friends of Dr Madeline Kerr learned of her death on August 22, a few months after she had resigned from her post of senior lecturer in social science in the University of Liverpool because of ill-health.

Dr Kerr was primarily a social psychologist, but the richness and variety of her interests in the cultural process took her work into the sociological and anthropological fields Dr. Kerr graduated at Manchester and, after working in the Psychological Service of the Liverpool Education Committee, returned to take up the Knight fellowship in psychological medicine At Manchester she was influenced by Prof T H Pear and retained an interest in the interaction of social status and personality traits From Manchester she went to London, where she took her doctorate and worked with Prof. Lancelot Hogben She then joined Prof Susan Stebbing to teach psychology in the Department of Philosophy at Bedford College She was a great admirer of Susan Stebbing and this was reflected in the logical austerity of her seminar teaching

In 1947 Dr. Kerr was given leave of absence to act as social psychologist to the West Indian Social Survey, where she organized a programme of psychological testing. In the West Indies, Dr Kerr found an environment in which her interests in the graphic and plastic arts and in music combined with her scientific interests to make her immediately acceptable to the subjects of her study, and she made lasting friendships with members of all classes in West Indian society from simple peasants to members of the Government Some of the findings of her work were published in *Personality and Conflict in Jamaica* (1952)

On her return to England it was natural that she should join Prof T S Simey, who had also worked in the West Indies, in the Department of Social Science of the University of Liverpool Here she continued her intensive investigation on families, and in 1958 published *The People of Ship Street*, which described the existence of a matriarchal society in a working-class area of Liverpool.

In Liverpool she devoted most of her energies and her great enthusiasm to her students, for whom nothing was too much trouble and with whom she made close and enduring friendships She will be greatly missed.

D CHAPMAN

NEWS and VIEWS

Royal Society Medal Awards

THE following awards of medals have been made by the President and the Council of the Royal Society. *Copley Medal* to Sir Hans Krebs, Whitley professor of biochemistry in the University of Oxford, for his distinguished contributions to biochemistry, in particular his work on the ornithine, tricarboxylic acid and glyoxylate cycles; *Davy Medal* to Prof. D. H. R. Barton, professor of organic chemistry in the Imperial College of Science and Technology, University of London, for his distinguished researches in organic chemistry, particularly on the structure and stereochemistry of natural products of the terpene and steroid series, and the analysis of the conformation of cyclic structures; *Sylvester Medal* to Prof. P. Hall, Sadleirian professor of pure mathematics in the University of Cambridge, for his distinguished researches in algebra; *Hughes Medal* to Prof. A. H. Cottrell, Goldsmiths' professor of metallurgy in the University of Cambridge, for his distinguished work on the physical properties of metals, particularly in relation to mechanical deformation and to the effects of irradiation.

David Sarnoff Award in Electronics :
Dr. C. H. Townes

DR. CHARLES H. TOWNES, a leading American physicist and provost of the Massachusetts Institute of Technology, has been presented with the David Sarnoff Award in Electronics of the American Institute of Electrical Engineers. The award cited Dr. Townes for research in physics leading to major advances in communication technology. He is well known for his work on the theory and application of masers, on which he holds the fundamental patent. Dr. Townes was appointed provost of the Massachusetts Institute of Technology earlier this year. He was a member of the technical staff of Bell Telephone Laboratories during 1939–47, then joined the faculty of Columbia University as associate professor of physics. He was appointed professor in 1950, served as executive director of the Columbia Radiation Laboratory during 1950–52 and as a chairman of the Physics Department during 1952–55. Dr. Townes's awards include the Morris Liebman Memorial Prize of the U.S. Institute of Radio Engineers (1958), the Stuart Ballantine Medal of the Franklin Institute (1959), the Comstock Award of the U.S. National Academy of Science (1959) and the Rumford Premium of the American Academy of Arts and Sciences (1961).

National Physical Laboratory :
Dr. J. V. Dunworth, C.B.E.

DR. J. V. DUNWORTH has been appointed deputy director of the National Physical Laboratory (Department of Scientific and Industrial Research) in succession to Dr. G. Macfarlane, who early next year will take up his recent appointment of director of the Royal Radar Establishment, Malvern (*Nature*, 192, 18; 1961). Dr. Dunworth is at present deputy director of the Atomic Energy Establishment, Winfrith. He is forty-four years of age and was born in Manchester and educated at Manchester Grammar School and the University of Cambridge. Shortly before the outbreak of war in 1939 he was invited to become a member of Sir John Cockcroft's team investigating problems in the use of radar. He continued in this work until 1944, working on 150-cm and 10-cm radar development, mainly at the Radar Research Establishments at Christchurch and Malvern. Late in 1944 he went to Canada with Sir John Cockcroft to work with the National Research Council on atomic energy development. Soon after the end of the War he returned to Cambridge to take up his fellowship at Trinity College and was appointed a demonstrator in physics in the Cavendish Laboratory. Later, in 1946, he rejoined Sir John Cockcroft at the Atomic Energy Research Establishment, Harwell.

The Botanical Survey of India : Prof. H. Santapau

FOR a long time the Botanical Survey of India remained in hibernation and the superintendent of the Sibpur Botanical Garden was also the officer-in-charge of the Botanical Survey with its headquarters in the Indian Museum at Calcutta. About eight years ago the Survey was re-organized and now has a new headquarters at Calcutta together with a number of regional offices in different parts of the country. Dr. J. C. Sen Gupta, who was chief botanist for the past several years, retired last summer and was succeeded a few months ago by Father H. Santapau, for many years professor of botany at St. Xavier's College, Bombay. Father Santapau was born in Spain in 1903. He went to India in 1928 and has ever since been intimately associated with educational institutions in India. Although his original education was in Barcelona in Spain, he later studied in the Royal College of Sciences and Imperial College of Science and Technology, London, from which he obtained the diplomas of A.R.C.S. and D.I.C. and the B.Sc. honours and Ph.D. degrees of the University of London. In 1947 he was elected Fellow of the Linnean Society of London and in 1953 a Fellow of the National Institute of Sciences of India. Father Santapau is the author of a large number of research papers and books dealing with the results of his explorations in parts of the Western Ghats (especially Mahabaleshwar) and the Dangs Forest in Saurashtra. A few years ago he wrote a comprehensive *Flora of Khandala* (a second edition of which has now been published) and in 1958 the *Flora of Purandhar*. Among his other publications special mention may be made of one on the *Acanthaceae of Bombay* and another dealing with a *History of Taxonomic Researches in India on the Angiosperms*.

Twenty-five Years of Television

DURING the first week of November, the British Broadcasting Corporation celebrated the inauguration of the world's first high-definition television service —on November 2, 1936 (*Nature*, 138, 394, 793; 1936). At the beginning two systems of transmission, the Baird and the Marconi-EMI, were used in alternate weeks to judge under practical conditions which was the better. After three months of this experimental service, and following the recommendation of H.M. Postmaster-General's Television Advisory Committee, the transmissions were confined to the Marconi-EMI system on a standard basis of interlaced scanning at

405 lines per picture, and a picture frequency of 25 per sec It was in this fashion that what is generally conceded to be the best public television service in the world opened well in advance of the United States, where the first public television transmissions did not start until April 1939

It is a tribute to the excellent pioneer work of the engineers and scientists who formulated the technical standards adopted by the Government in 1937 to note that these have remained unchanged in Britain for twenty-five years Associated with the celebrations of this silver jubilee was a dinner given by the British Broadcasting Corporation at Grocers' Hall, on November 7, presided over by Sir Arthur fforde, chairman of the B B C The Prime Minister proposed the toast of the service and paid tribute to the pioneer work of all those concerned not only with the technical achievement but also with the foundation of the new techniques of programme provision and presentation, for both informative and entertainment purposes Many of those responsible for these developments were present on this occasion, and they and their successors must have been encouraged to work towards the further developments which will undoubtedly occur in the next quarter of a century

Milk Powder

Even the richest cows' milk contains some 86 per cent of water, and it has long been realized that if milk could be dried satisfactorily at a moderate cost to produce a product with practically the same nutritive value as the raw milk from which it came, the resulting powder would have many important uses It is not surprising to find, therefore, that the manufacture and use of dried milk are greatly increasing in many parts of the world, and that even in Britain the amount now made is three times as much as it was before the Second World War The Government's Milk and Milk Products Technical Advisory Committee, realizing that many potential users of milk powder might not know of the merits and value of the modern product, or about the different types that are available, sponsored the preparation of a booklet by its Milk Products Sub-Committee (Ministry of Agriculture, Fisheries and Food, Department of Agriculture and Fisheries for Scotland, Department of Health for Scotland *Milk Powder* Pp v+18 (London H M S O , 1961) 1*s* 3*d*)

The booklet succeeds in giving a most valuable account of the subject, and is divided into two parts, the first of which deals with the manufacture of milk powders, their composition, bacteriology, bulk reconstitution to form liquid milk and their nutritive value The first part contains also a section on the physical and chemical properties of milk powders in which important properties such as particle size and shape, bulk density, flow properties and solubility and dispersibility in water are discussed The second part gives an account of the commercial uses of dried milks in baking and in the manufacture of margarine, chocolate, manufactured meat products, soups and ice-cream It deals also with the use of milk powder in canteens and institutions, and with its value in feeding-stuffs for certain classes of farm livestock such as very young calves, chicks and turkey poults The booklet ends with a list of eighteen references from which further details can be obtained This small but most informative booklet will long remain a standard work of reference on a subject which is bound to increase in importance as food science and food technology develop with increasing application of these subjects to world food problems

Royal Ontario Museum : New Mineral and Gem Gallery

A new mineral and gem gallery at the Royal Ontario Museum, University of Toronto, has been financed by a 75,000 dollar grant from the International Nickel Company of Canada, Ltd The exhibit of minerals on show in the Gallery will include material from the Leonard Collection of gemstones, the Andre Dorfman Collection of minerals and the MacIntyre–Porcupine Collection of gold ore and nuggets The mineralogy collections now at the Royal Ontario Museum were begun at Victoria College, Cobourg, at the end of the nineteenth century, at the Provincial Museum, Toronto, and with the purchase by the University of Toronto of one of the collections assembled by the late Dr W F. Ferrier In 1912, when the Royal Ontario Museum was established, these collections were brought together.

The Cotton, Silk and Man-made Fibres Research Association

Speaking at the annual general meeting of the Cotton, Silk and Man-made Fibres Research Association on October 12, the director, Dr D W Hill, said that the work of the Association was now organized in fourteen departments, of which five were newly constituted, and the research programme was controlled by a new Research Committee served by nine sub-committees, including two new ones All the 110 members of staff declared redundant on the merging of the two research associations had found satisfactory positions elsewhere The report of the Council, presented at the annual meeting, in describing research and development during the year refers to the application of the principle of the Shirley 'automatic size box' to the feed-box of a mangle and to progress in overcoming difficulties associated with a self-brushing device for laying the fibres in warps during sizing It also refers to work on heat transmission through assemblies of aluminized fabrics and cotton blankets with the view of providing information on which can be based the design of clothing for protection under conditions more exacting than those met in ordinary life Special attention has been paid to the development of a cold-pad process for bleaching cotton–acetate unions without hydrolysing or delustring the acetate, and considerable progress has been made in work on the flow of liquids in contact with or through textiles Work of package dyeing has directed attention to methods of achieving complete wetting-out of the package

Men and their Jobs

For his inaugural lecture delivered at Birkbeck College, University of London, on October 16, Prof Alec Rodger took as his title "Occupational Versatility and Planned Procrastination". Prof Rodger indicated that existing surveys to discover the requirements of man-power are usually inaccurate, and that, despite what is being done to prevent occupational waste, there is much human wastage for which remedial work has to be done. At present, 10,000 cases pass through the industrial rehabilitation units of the Ministry of Labour each year Prof Rodger suggested that facilities which are at present intended mainly for the disabled or chronically employed should be extended to other sections of the community. With ten more occupational psychologists in the Ministry of Labour, considerable help could be given in providing better guidance for both adults and young people To avoid real human waste, however, the training people received for jobs should be given the widest possible base, and specialization should be postponed as long as possible, until the individual and his advisers are reasonably sure he is in the right occupation or profession

Nature Reserves

The forty-fourth annual report of the Society for the Promotion of Nature Reserves for the year ending March 31 is largely made up of accounts of the activities at the fourteen reserves which come under the jurisdiction of the Society (Pp 44+2 plates. London: Society for the Promotion of Nature Reserves, British Museum (Natural History), 1961. 10*s*.). At Woodwalton Fen, Huntingdonshire, a study of the breeding biology of the large copper butterfly was continued and the eggs and larvæ on more than a thousand food-plants are being counted at regular intervals. Observations will be carried out on the preference shown by the butterflies when egg-laying for docks growing in the open fen and those growing in the dykeside. Suggestions for introducing the butterfly on an experimental basis to Blackmoor Copse Nature Reserve, Wiltshire, have been considered, but it has now been decided to postpone a decision until further observations have been made at Woodwalton Fen. A spider new to the British list, *Asagena phalerata,* was recorded at Linwood Warren Nature Reserve, while at Calf of Man, Isle of Man, a red-breasted flycatcher (the second Manx record) was captured in June, and Manx shearwaters were taken on land during the summer. The Manx shearwater has not been seen on the island for nearly two hundred years. At Belfairs Great Wood, Essex, the reed mace grass veneer (*Crambus paludellus* Hubner) has now occurred two years running in a garden abutting on the Reserve, and is probably breeding on reed mace in one of the small ponds

Electrotechnology in Australia

In the annual report of the Division of Electrotechnology of the Australian Commonwealth Scientific and Industrial Research Organization for the year ended June 30, 1960, reference is made to the three-weeks visit paid by Prof. H Frohlich, professor of theoretical physics in the University of Liverpool, to Australia at the invitation of the Division The object of the visit was to discuss and advise on the various aspects of the research work of the Dielectrics Section of the Division, which is concerned with the study of the alkali halides, aliphatic long-chain compounds—particularly the growth of large single crystals and the production of pure compounds, the hydrates of calcium sulphate; and the theories of dielectric loss and of superconductivity The Division is responsible for the maintenance of the Commonwealth standards of measurement of electrical and magnetic quantities, and its activities are dealt with separately in the annual report under the headings of direct current, power frequency, audio- and radio-frequency, and magnetics With the completion of the calculable capacitor, considerable progress has been made with necessary additional equipment and techniques for the absolute determination of the ohm. The screening efficiency of screened rooms with especial emphasis on the microwave region of the spectrum has been investigated, and work on the probability problems associated with various random processes has been carried out experimentally by means of the probability distribution analyser designed and constructed in the Division. The report concludes with a list of the publications by members of the staff, and their names and positions as at June 30, 1960

Solid Propellant Test Rig

Messrs P. A. Hilton and Co, engineers, of Radlett, Hertfordshire, announce that they have completed the development of a solid propellant rocket motor test rig for use in universities and technical colleges. The rig consists of a stainless steel rocket motor suspended on a swinging parallel motion linkage which pushes against a cantilever spring beam. Movement under load is transmitted to a pen recorder indicating thrust, on paper moved at constant speed by a synchronous electric motor The area of the diagram produced is related by the calibration to the total impulse Chamber pressure is transmitted by flexible pipe to a bourdon tube which in turn operates a recorder pen running parallel with the thrust pen. The fuel used is a form of cordite supplied in cartridge form giving a specific impulse of about 180 sec and requiring no more elaborate storage facilities than are accorded to shotgun ammunition. The motor is equipped with a blow-out diaphragm to diminish explosion risks The rig permits measurement of thrust, total impulse, specific impulse and burning time, and it is possible to study the effect of chamber pressure and nozzle design on these quantities by substituting nozzles of different diameters and profiles

The rig is of simple design, of which the recorder is the weakest link, since it is not certain that the relation between diagram area and total impulse is strictly linear and since the mechanism for applying tension to the paper is rather crude. The rig, however, should prove valuable for teaching and demonstrating in engineering departments wherever an interest in rocket motors and combustion exists and it has been constructed on a scale such that departments with quite limited facilities can use it The rig is a welcome addition to the very limited range of standard teaching apparatus available in the sphere of gas dynamics and combustion Further details can be obtained from the manufacturers.

Summer School in Analytical Chemistry

The fifth triennial summer school in analytical chemistry, organized by the Royal Institute of Chemistry with the participation of the Society for Analytical Chemistry, will be held in the Manchester College of Science and Technology during September 9–15, 1962. The School will consist of four separate, but concurrent, courses· *Course* 1, "Physical Methods of Organic Chemistry", under the direction of Dr. D W Mathieson, reader in pharmaceutical chemistry, School of Pharmacy, London, *Course* 2, "Recent Developments in Inorganic Analysis", under the direction of Mr W T Elwell, chief analyst, Imperial Chemical Industries, Ltd, Metals Division, Witton, Birmingham, *Course* 3, "The Determination of Toxic Substances in the Air and in Effluents", under the direction of Mr H. E Stagg, chief analyst, Imperial Chemical Industries, Ltd., Dyestuffs Division, Blackley, Manchester, *Course* 4, "Newer Instrumental Techniques", under the direction of Dr. V. S. Griffiths, reader in spectroscopy, Battersea College of Technology, London. Further information can be obtained from the Education Officer, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

Theoretical Chemistry Summer School at Oxford

Once again Prof. C. A. Coulson and the Delegacy for Extra-Mural Studies of the University of Oxford are organizing a summer school in theoretical chemistry. The school is to be housed in St. Antony's College, with lectures in the Mathematical Institute. Further information may be obtained from the Secretary, Delegacy for Extra-Mural Studies, Rewley House, Wellington Square, Oxford. The dates of the School are September 8–22, 1962, accommodation is strictly limited and the closing date for applications is April 30, 1962.

British Institution of Radio Engineers: Awards

The following awards have been made by the British Institution of Radio Engineers for outstanding papers published in the Institution's *Journal* during 1960: *Clerk Maxwell Premium*, to Dr. G. T. Wright (University of Birmingham) for his paper on "A Proposed Space-Charge-Limited Dielectric Triode"; *Heinrich Hertz Premium*, to Mr. R. A. Waldron (Baddow Research Laboratories, Marconi's Wireless Telegraph Co.) for his paper on "Features of Cylindrical Waveguides containing Gyromagnetic Media"; *A. F. Bulgin Premium*, to Dr. A. Kraus (Rohde and Schwarz, Munich) for his paper on "Reflection Coefficient Curves of Compensated Discontinuities on Coaxial Lines and the Determination of the Optimum Dimensions"; *Arthur Gay Premium*, to Mr. E. Davies (Marconi's Wireless Telegraph Co.) for his paper on "The Application of Printed Wiring to Development of Small Batch Production with Particular Reference to Television Equipment"; *Leslie McMichael Premium*, to Mr. C. H. Dix and Mr. W. E. Willshaw (Hirst Research Centre of the General Electric Co.) for their joint paper on "Microwave Valves: a Survey of Evolution, Principles of Operation and Basic Characteristics"; *Lord Rutherford Award*, to Mr. E. C. Fellows (Associated Electrical Industries Research Laboratories, Aldermaston) for his paper on "Energy Stabilization of a 4-MeV Electrostatic Accelerator using Controlled Corona Discharge"; *Charles Babbage Award*, to Mr. E. M. Bradley (International Computers and Tabulators) for his paper on "A Computer Storage Matrix using Ferromagnetic Thin Films".

The Night Sky in December

New moon occurs on Dec. 7d. 23h. 52m. U.T. and full moon on Dec. 22d. 00h. 42m. The following conjunctions with the Moon take place: Dec. 11d. 00h., Saturn 2° S.; Dec. 11d. 14h., Jupiter 2° S.; Dec. 20d. 11h., Aldebaran 0·7° S.; Dec. 26d. 21h., Regulus 0·5° S. In addition to these conjunctions with the Moon, Venus is in conjunction with Antares on Dec. 11d. 20h., Venus being 5° N. Mercury and Mars are too close to the Sun for observation. Venus is a morning star, but is also too close to the Sun for easy observation. Jupiter and Saturn are evening stars, setting about three hours after the Sun, but conditions for observation are not favourable. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Dec. 1d. 1h. 19·3m., σ Leo (*D*); Dec. 1d. 2h. 13·5m., σ Leo (*R*); Dec. 12d. 17h. 56·7m., 45 Cap (*D*); Dec. 18d. 19h. 46·6m., + 11° 445 (*D*); Dec. 20d. 4h. 25·0m., γ Tau (*D*); Dec. 23d. 23h. 30·4m., 81 Gem. (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The Geminid meteors are active during December 9–14, maximum activity being on December 13. The radiant is at R.A. 7h. 28m., Dec. + 32°, and conditions for observation are very favourable. The Ursid meteors are active on December 20–22, but conditions for observation are unfavourable. The winter solstice occurs on December 22d. 03h.

Announcements

Mr. R. Blyth has been appointed editor of *The Pharmaceutical Journal*. He has been responsible for the *Journal* since June this year. He joined the *Journal* as assistant editor in 1957 from the same post on *The Chemist and Druggist*.

The Royal Agricultural Society of England offers annually a medal together with an award of one hundred guineas for research work of outstanding merit carried out in the United Kingdom which has proved, or is likely to prove, of benefit to agriculture. Recommendations from heads of university departments or research organizations for the next award must be submitted to the Secretary, Royal Agricultural Society of England, 35 Belgrave Square, London, S.W.1, not later than January 31, 1962.

A symposium on "The Role of Science in the Development of Natural Resources with particular reference to Iran, Pakistan and Turkey" is to be held in Lahore during January 8–13. The symposium is sponsored by the Scientific Council of the Central Treaty Organization.

The sixty-eighth annual meeting of the American Mathematical Society will be held in Cincinnati, Ohio, during January 22–25, in conjunction with the annual meeting of the Mathematical Association of America. Further information can be obtained from the associate secretary, J. W. T. Youngs, American Mathematical Society, 190 Hope Street, Providence 6, Rhode Island.

The Department of Municipal Engineering of the Manchester College of Science and Technology is organizing a short course of lectures on "Problems of Radioactivity at Water and Sewage Works", which will be held in the College during January 11–12. Further information can be obtained from the Registrar, Manchester College of Science and Technology, Manchester 1.

The International Atomic Energy Agency is organizing a conference on "New Techniques in Biology and Medicine" at Mexico City during November 21–December 1. Special attention will be directed to the use of isotopes in these fields. Further information can be obtained from the International Atomic Energy Agency, Vienna.

The Chemical Research Committee of the Indian Council of Scientific and Industrial Research is organizing a symposium on "Carbohydrates, Cellulose and Cellulose Industries" at Ahmedabad Textile Industry's Research Association, Ahmedabad 9, during January 29–30, 1962. Further information can be obtained from the Director, Ahmedabad Textile Industry's Research Association.

The name of one of the authors of the communication entitled "Mouse Lymphoma Cells with Different Radiosensitivities" in *Nature* of November 11, p. 572, was omitted; the communication was by Dr. P. Alexander and Z. B. Mikulski.

THE UNIVERSITY OF OXFORD EXPEDITION TO PERU, 1961

THE University of Oxford Expedition to Peru, 1961, has recently returned to the United Kingdom after completing approximately three months field work in the Central Andean Region south of Huancayo. The investigated area covered 600 sq miles between latitudes 12° 25′ and 12° 50′ S , and longitude 75° 15′ and 75° 30′ W , at altitudes from 13,000 to 18,000 ft O D Six scientists completed an integrated study which concentrated on the geological and botanical features of the country

No previous work had been done on the geology of the area although the region was adjacent to country mapped by Dr J V Harrison of the Department of Geology and Mineralogy, Oxford R C Herrera constructed an initial geological map on the scale 1 50,000 This work was augmented by detailed stratigraphical sections of the Mesozoic and Tertiary, and by systematic collection of fossils, especially from the Cretaceous limestones A small number of volcanic and acid intrusive specimens were collected for Prof B Giletti of Brown University, in conjunction with a programme of age determination of Andean rocks The results of the investigation will be used by Dr J J Wilson, of Lima, in his work on the Mesozoic history of the Andean Geosyncline

The botanical work, carried out by J R Lloyd and J K Marshall, was divided into five parts First, a collection was made of the flowering plants, ferns and bryophytes of the whole area Concomitantly, a map and general survey of the plant formations in the region were completed Thirdly, the quadrat method was used for a more intensive examination of samples from the formations of all districts. Completeness and precision were given to this phase by the detailed study of all the communities of a selected 10 sq mile plot Material comparable with the recently discovered fern-allay, *Stylites*, was found to be widespread in the *Distichia* bogs, and an autecological investigation was made of this and other genera Finally, analysis of the changes of day and night temperature of four different flowering plant genera was carried out. The botanists were accompanied for a short time by Dr O Tovard, a Peruvian taxonomist, who aided in collecting and general survey

S R S Walker carried out work on the various soils, the majority of which were skeletal lithosols with a marked absence of horizons His work was closely linked with the ecological programme of the botanists, and the samples will be analysed at the Department of Botany, Cambridge.

A 1 50,000 map of the north-eastern part of the area was compiled by the surveyor, M R Bewsher, this supplemented the smaller-scale published maps, Stadia methods were used to map at 1 5,000 a limited area of particular interest to the botanists In addition, Bewsher recorded continuous meteorological observations at six stations

M J Troughton undertook a geographical description of the study area, and in particular of the Ayhuicha Valley centred on the village of San José de Acobambilla This is an isolated and particularly self-sufficient peasant community, and he was fortunate in being able to carry out the investigation during the 'faena' or collective community work period. At this time the men are recalled to the village from work among the herds on the puna grazing areas, thus presenting a good opportunity of observing the various activities of such a population.

Throughout the Expedition, great use was made of animal transport—mainly pack mules, which, in spite of their temperament, were ideally suited to the rough mountainous terrain. The mules, the extreme hospitality of the local Indians, and a working knowledge of Spanish were found to be great aids to exploration in the Andes of Peru. R. C. HERRERA

ELECTRON MICROSCOPY IN THE UNITED STATES

THE nineteenth annual meeting of the Electron Microscope Society of America was held at the Pittsburgh Hilton Hotel, Pittsburgh, Pennsylvania, during August 23-26 The Local Arrangements Committee, headed by Dr Robert V Rice, is to be especially commended for the arrangement and success of this meeting, which brought together more than 706 active workers in electron microscopy from 24 American States, Canada, Australia, Great Britain, Belgium, Germany and Japan It was the largest meeting in the history of the Society There were ten general sessions of contributed papers, five in the biological fields, five in non-biological areas , in addition, a special session on techniques and three symposia were features of the programme Nineteen scientific exhibits were presented and twenty-one commercial exhibitors participated in the meeting. Some 180 authors contributed papers on the technique and applications of the electron microscope to work in biology, chemistry, medicine, cancer, metallurgy, electron diffraction and related fields

A limited number of programme abstracts are still available from Dr A R Taylor, Parke, Davis and Co , Detroit, Michigan One hundred and three new members of the Society were elected, making the total membership 1,040.

In the symposium on "The Contribution of Electron Microscopy to Polymer Morphology", organized by Dr R G Scott (Pioneering Research Division, DuPont Experimental Station, Wilmington 98, Delaware), seven experts in this field discussed X-ray diffraction applied to polymers, spherulites, electron diffraction applied to single crystals, morphology of polymers, fibre microscopy and electron diffraction applied to synthetic fibres Arrangements for this symposium were planned over a period of two years and summarized the new phases of technology and applications of electron microscopy in the field of polymer science.

Dr Rubin Borasky (Electron Microscope Laboratory, Graduate College, University of Illinois, Urbana, Illinois) arranged and directed the symposium on "Ultrastructure of Protein Fibers—Collagen, Muscle, and Keratin" The papers on physical, chemical and mechanical properties of protein fibres in muscle and keratin summarized the recent contributions to the science of fibre structure, especially collagen.

The symposium on "The Fine Structure of Viruses" arranged by Dr. A. F. Howatson (Medical Biophysics Department, University of Toronto, Toronto 5, Ontario) was especially noteworthy in that the presentation of papers on recent advances in fine structure, animal virus structure, electron microscopy of nucleic acids and proteins, structures of bacteriophages and their variations, and work on the fine structure of foot-and-mouth disease virus brought together in a very logical sequence the information on the recent improvements in the techniques of replication, shadow-casting, thin sectioning and "negative contrast" staining and their application and interrelationships in obtaining new information on the structure of viruses both *in situ* and isolated.

Fifth International Congress for Electron Microscopy

Arrangements for the Fifth International Congress for Electron Microscopy to be held in Philadelphia during August 29–September 5, 1962, were announced at the meeting.

The Electron Microscope Society of America will be the host for the International Federation of Electron Microscope Societies at this Congress to be held, coincidently, on the twentieth anniversary of the Electron Microscope Society of America. Efforts are being made to have the Congress include the most significant developments since the last Congress in Berlin in 1958. The general theme will emphasize new and unique contributions of electron microscopy toward the advancement of science. In addition to contributed papers, the programme is being organized to include special papers by invited speakers which will set the theme of each session. In the interest of the earliest possible dissemination of the new material to be presented at the Congress, the Committee has completed arrangements for each active member at the Congress to receive the bound copy of the scientific papers at the time of registration. This will contain an abbreviated paper, including some micrographs or illustrations, for each scientific contribution presented at the Congress.

Further information can be obtained from the Secretary, Fifth International Congress for Electron Microscopy, 7701 Burholme Avenue, Philadelphia 11, Pennsylvania.

A. R. Taylor

THERMIONIC CONVERSION OF HEAT TO ELECTRICITY

A SYMPOSIUM on the thermionic generation of electricity was held at Bankside House, London, on May 11. It was organized by the Central Electricity Generating Board and attended by workers in the field of thermionic generation from a number of public and private concerns in Britain.

An opening address by Dr. K. H. Spring, of the Research and Development Department of the Central Electricity Generating Board, was followed by a paper from Mr. R. V. Harrowell, also of the Board, and Dr. J. Myatt (Atomic Energy Research Establishment, Harwell) on the efficiency and power of a diode generator. This paper examined the simplified expression for efficiency

$$\eta = \frac{\varphi_c - \varphi_A}{\varphi_c + P_L/I_A}$$

where φ_c and φ_A are cathode and anode work functions, P_L is the power loss and I_A is the anode current. When η is plotted against φ_c, the resulting humped curve is asymptotic to zero efficiency as φ_c is increased indefinitely, and for $\varphi_c = \varphi_A$, $\eta = 0$. It was pointed out that emphasis is seldom laid on the fact that this efficiency curve is valid only for a matched load at each value of φ_c: it is then true that $\eta = 0$ at $\varphi_c = \varphi_A$. But it is quite possible, under non-matched conditions, to have a high efficiency even when $\varphi_c = \varphi_A$, and this, or an intermediate state, may be desirable in certain circumstances. More important is the fact that, under matched conditions, maximum efficiency may sometimes be sacrificed for an increase in power, in this case φ_c will be less than its value at maximum efficiency.

A low anode work-function is important for the realization of high efficiency. The effective work-function of a metal anode in cæsium vapour depends on the cæsium coverage of the surface. A value below both the figure for clean metal and the bulk cæsium work-function can be achieved with a correct balance between the anode temperature and the saturated cæsium temperature: a value of 1·1 V has been quoted.

A study of the work-functions of anodes opposite oxide cathodes has been made by Dr. B. J. Hopkins (University of Southampton). The work-function of a clean nickel anode (~ 4·7 V) fell to less than 2·5 V. when the cathode was in the most active condition. Dr. Hopkins considers that barium oxide evaporates from the cathode in the molecular form and is deposited on the anode. Three methods of measurement were used: two depend on the determination of the contact potential difference from retarding field curves, the other uses the contact potential difference obtained by the Kelvin method. If the contact potential difference between the cathode and a known reference surface is also measured, then the anode work-function can be found by eliminating the cathode work-function from the two expressions, alternatively, the cathode work-function can be measured from a Richardson plot, although this would give a less trustworthy result.

Mr. D. C. Gore (Central Electricity Generating Board) read a paper entitled "The Thermionic Diode in Large-Scale Power Production from Fossil Fuels". This dealt with the diode as a thermodynamic topping device in a conventional boiler, using the upper part of the available temperature-range, which is not usable in a steam cycle. The mechanical arrangement would be for the diodes, in cylindrical form, to envelop the boiler tubes, the outer, cylindrical cathodes would be heated by the furnace gases. If a diode efficiency of 20 per cent could be attained and the efficiency of the conventional plant were 35 per cent, the total plant efficiency would be raised to 45 per cent by the introduction of diode 'toppers' passing three-quarters of the available heat. Any saving in fuel costs would probably be considerably offset by the relatively short life of the diodes, but Mr. Gore believes that if the very difficult problems of materials can be solved there are reasonable prospects for reducing generating costs. Some of the problems of materials and techniques were then reviewed by Mr. E. Cohen (Central Electricity Generating Board).

Mr. D. A. Watt (Atomic Energy Research Establishment, Harwell) and Mr. J. A. McWilliams (Boucher and Co., Kidderminster) described two engineering design studies of experimental in-pile thermionic generators: one has a planar geometry and uses ceramic–metal seals, the other, with a cylindrical geometry, has been simplified by omitting the ceramic–metal seals and using a continuous stainless steel envelope, which also forms the anode load. In the planar device the cathode is a coating of natural or depleted uranium carbide–zirconium carbide (25 · 75) on a tantalum 'top-hat', the inside of which contains uranium carbide–zirconium carbide enriched with uranium-235 as the fuel. To overcome the serious compatibility problem of fuel material in contact with tantalum at 2,000° C., the cylindrical version uses a rod of uranium carbide–zirconium carbide made of depleted or natural material at the end in contact with the tantalum cathode support and enriched material as the fuel at the free end. An output of about 300 W. was expected from an experimental model of the cylindrical diode being made.

The use of ion injection for space charge neutralization was discussed in a paper by Mr. G. G. Isaacs (G.E.C. Hirst Research Centre). In this type of device, ions are generated by an auxiliary discharge and, therefore, inert gases may be used instead of the chemically active alkali metal vapours. The experiments reported indicated a high degree of neutralization of space charge. A net output of about 200 mW. was obtained at an efficiency of about 1 per cent, however, no attempt had been made to optimize the design. As well as freedom of choice of filling gas, a further advantage of this kind of device is its potentiality for generating alternating current.

Mr. J. A. Thorp (A.E.I., Rugby) spoke on "Auxiliary Ion Sources in Cæsium Diodes". One method of neutralization of space charge is to produce positive ions from cæsium atoms in contact with a hot surface the work-function of which exceeds the ionization potential of cæsium. Mr. Thorp dealt with an investigation using matrix-type cathodes of low average work-function but with some high work-function spots at which ionization occurs. It is possible, however, for some ions to be trapped in a potential well at the mixed work-function surface and thereby be rendered ineffective. In the work described, a hot tungsten filament between anode and cathode has been used to ionize the cæsium. When the filament was biased one or two volts positive relative to the cathode, the anode current was several times greater than when the ionizer was unbiased. This indicated that the potential well at the filament was removed and positive ions were released.

In an analysis of the processes of ionization and de-ionization in a diode, Dr. L. G. Sanders (Atomic Energy Research Establishment, Harwell) considered the comparative effects of ionization by electron collisions and photons, and the so-called resonance ionization (also used by Mr. Thorp). It appears that the first two types of ionization are small compared with resonance ionization at the cathode, provided, in the case of electron collisions, that the electrons are at cathode temperature. However, if the electrons are at a temperature two or three times greater than the cathode temperature of about 2,000° C., electron collision ionization can make an appreciable contribution. The electron temperature may well be of this order due to barrier and Thomson heating. A simple approach, based on the current balance at the electrodes, has shown that the highest vapour pressure necessary is that which just neutralizes the negative space charge. If the pressure has to be higher than this amount in order to lower the cathode work-function by partial cæsium coverage, then the electrode spacing should be decreased to limit the plasma resistance.

In a review of progress in the United States, Dr. B. C. Lindley (C. A. Parsons and Co., Ltd.) reported that the trend there is towards the use of refractory metal cathodes and high cæsium pressures: the former enables high cathode temperatures to be used, while the high vapour pressure (~ 10 mm. mercury) ensures, even at 2,000° C., a reduction in work-function due to the presence of a monolayer of cæsium, electrode spacings of the order of the electron mean free path minimize heat conduction through the plasma. Most of the American groups visited were working on the close-spaced vacuum converter as well as the cæsium version.

"The Crossed Field Thermionic Converter" was the title of the final paper, which was read by Dr. G. D. Sims (University College, London). In this device, space charge is overcome by crossed electric and magnetic fields. Dr. Sims described experiments that have established beam interaction with the accelerator electrode in the initial apparatus used. He believes there is little doubt that the accelerator current, which persists even with extremely high magnetic fields, arises as a result of instability in the electron cloud, this gives rise to either amplification of noise or oscillation—resulting in radio-frequency fields which cause electrons to lose sufficient energy to be drawn to the accelerator. This represents wasted power. Further experiments are being planned with the view of the suppression of accelerator current.

R. V. HARROWELL

RESEARCH IN THE LEATHER INDUSTRY

THE seventh biennial conference of the International Union of Leather Chemists Societies was held in Washington, D.C., during August 20–25.

The International Union was founded in Europe after the Second World War as a confederation of national member societies concerned with the leather industry, and research and technology related to it. From an early stage in its development, it had as one of its members the American Leather Chemists' Association, and in the twelve years since its foundation it has come to include among its twenty-five member societies a steadily increasing number from Asia, Africa and South America, the expanding leather industries of which are based on locally available supplies of hides, skins and tanning materials. The decision to hold this year's biennial conference outside Europe for the first time, and to combine it with the annual meetings of the American Leather Chemists' Association, is evidence of the growing collaboration between American and European leather chemists and their colleagues in other continents. Thanks to its efficient organization by the host society an enjoyable, lively and instructive conference resulted

As a craft industry, organized in relatively small units, the leather industry has in the past paid too little attention to the more fundamental types of research, and is to-day still handicapped in competition with the producers of synthetic and substitute materials by the allocation of insufficient funds to research and development Not only the scale of research effort needs to be increased, however, but also the communication of the results in a form in which they are assimilable and can be applied in tanneries These points were emphasized by M Riviere (Strasbourg) in the John Arthur Wilson Memorial Lecture with which the conference began, and also by speakers in the ensuing discussions, public and private It was evident that there was a deeply felt need for closer collaboration between research workers and the industry, and that while national and international conferences such as the present one help to disseminate scientific information among the research workers, they do not necessarily ensure that this information is put to the best practical use in the industry itself, to achieve this, a programme of education is needed to acquaint the tanner with scientific discoveries which he can use, but also to acquaint the scientist with the needs and difficulties of the industry

Of the sessions which were devoted to scientific papers, the outstanding ones were those devoted to work on the chemistry and structure of collagen. The president of the Union, W Grassmann (Max-Planck Institut, Munich), reviewed present knowledge of this subject as a preliminary to a discussion of the results recently obtained by his group The light and dark bands revealed by electron microscope photographs of collagen fibrils have different amino-acid compositions By the investigation of peptides isolated from heat-denatured collagen by degradation with trypsin, it has been shown that some regions of the peptide chains contain more of the polar amino-acids than occur elsewhere, while in other regions the amino-acids are mainly glycine, proline and hydroxyproline, with some alanine and serine In the non-polar regions, the sequence is usually glycine–proline–*X*, where *X* is either glycine, serine or alanine In the polar regions, which give the dark bands, the sequence is less regular, and glycine does not occur at every third position Carefully controlled denaturation of tropocollagen (soluble collagen obtained by leaching young skins in mildly acidic conditions) results in the production from collagen (mol. wt 360,000) of α-collagen of mol wt 110,000 and β-collagen of mol wt 215,000 in equal amounts, and the denaturation is thought to cause multiple breaks in the rod-like tropocollagen, following the uncoiling of the collagen helices. According to F O Schmitt *et al*, the long spacing segments are built up of parallel bundles of tropocollagen molecules, whereas in the fibrils of native collagen, neighbouring molecules are displaced relative to one another by one-quarter of their length, and this view has been confirmed by staining techniques followed by photometric measurements along the lengths of the segments The collagen molecules are bound together laterally by covalent cross-links, which are the cause of the limited swelling and the insolubility of collagen in water As was shown in a paper by H Hörmann (Max-Planck Institut), the covalent bonds consist of hexoses the two hydroxyl groups of which form ester links between different peptide chains in collagen Grassmann indicated that tannage consists generally of an increase of cross-linking of molecular chains within dark band regions of fibrils, although some tanning materials also form compact deposits surrounding the fibrils, and without any true tanning action

K Kuhn (Heidelberg) described experiments on the end-to-end linkage of tropocollagen molecules involving their treatment with trypsin and pepsin to remove the peptide appendages which are thought to protrude from the ends of these molecules The results were held to indicate that the end-to-end polymerization of tropocollagen molecules was mainly due to electrostatic forces, but this view was questioned by Schmitt in the discussion following the paper The production of gelatin fractions from skin collagens, and their re-constitution as fibres, was described in a paper by A Veis and J Anesey (Northwestern University, Chicago) with J Cohen (Armour Leather Co, Chicago), while A G Ward, N T Crosby, D G Higgs, R Reed and G Stainsby (University of Leeds) described experiments the aim of which was to break the insolubilizing cross-links of mature bovine collagen after alkaline pretreatment The rod-like particles of collagen may be dissolved to yield products similar in many respects to those from young skin Some beautiful electron microscope photographs were shown by L P Witnauer and L D Kahn (Eastern Regional Laboratory, U S. Department of Agriculture, Philadelphia), collagen fibrils precipitated by inorganic ions from solution had various solubility characteristics, as well as a variety of forms

Of the other twenty-five papers presented at the conference, the majority were concerned with leather technology rather than with questions of general scientific interest, and reference can be made to only a few of them H G Turley (Rohm and Haas Co, Philadelphia) compared and contrasted American and European practice in chrome tanning, and indicated that the different methods used are determined by economic factors as much as by different objectives P J van Vlimmeren (T N O, Waalwijk, Holland) described work on masked chrome tannages, stressing the importance of the stage at which the masking agent (formate, phthalate, acetate or oxalate) is added to the tanning liquor Because of the different rates at which chrome complexes are formed, the most appropriate stage differs for various masking agents and, when chrome sulphate alone is used, it may be best to add the material to pickled pelt as a dry powder produced by the slow evaporation of chrome sulphate solution, this gives strongly masked anionic complexes which break down only slowly in cold solutions E Heidemann, P. Fuhren and H Kroll (Technische Hochschule, Darmstadt) discussed the tannages of synthetic polypeptides (used as model substances) with chrome They have produced them as gelatinous materials or as voluminous flakes in which all the carboxyl groups are probably accessible to chrome complexes, and their results suggest that the majority of the cross-linkages between carboxyl groups involve complexes containing a pair of chromium atoms

In a session devoted mainly to the physical testing of leather, E Baumann (Bally Shoe Factories, Schoenenwerd, Switzerland) stressed the need for simple and rapid test methods, which are essential in testing a biological material such as leather for factory control The abrasion testing of sole leather was discussed by R G. Mitton, M Millar and F R

Morgan (British Leather Manufacturers' Research Association), who showed that, despite the obvious complexity of the wearing process of shoe soles, there is a good correlation between the results obtained in abrasion tests and durability measured in wear trials of shoes. In favourable cases, the closeness of the correlation seems to be limited by the unavoidable errors associated with the wear trials (and amounting to a few per cent) rather than to any other cause.

R. G. MITTON

INTERNATIONAL UNION OF FOREST RESEARCH ORGANIZATIONS

THE thirteenth Congress of the International Union of Forest Research Organizations was held in Vienna during September 11–16 under the presidency of Mr. James Macdonald, director of research and education in the Forestry Commission, London. Vienna was the birth-place of the Union, and the small body of specialists, members of Austrian, German and Swiss forest research institutes, who first met (at Mariabrunn) in 1893, would surely have been gratified at the ramifying growth and vigour of their brain-child. More than 400 delegates, an all-time record, attended the Congress from about three dozen countries, with particularly strong contingents from Finland, Germany, Japan, Scandinavia, the United States and the U.S.S.R.

All working sessions were held at the Wilhelm Exner Haus, Hochschule fur Bodenkultur, and the opening and closing ceremonies at the more central Haus der Industrie. The Congress was formally opened by the Federal Minister of Agriculture and Forestry, who reviewed the great changes—territorial losses, damage, over-exploitation and neglect—wrought by two World Wars in the forest economy of Austria and emphasized the growing importance of the forests, both State and private, not only as suppliers of timber, internally and abroad, but also as stabilizers of mountain slopes and guarantors of the water supply. The Marshall Plan had given a great impetus to rehabilitation, and now an extensive programme of torrent- and avalanche-control, embracing both engineering works and reforestation, was under way, backed by a carefully conceived plan of research.

The main work of the Congress was, as usual, carried out in the sections, of which (inclusive of bibliography) there were ten, which constitute the living heart of the Union. The section leaders, who continue in office between Congresses, are responsible for keeping in touch with the research workers in their respective fields of action, for distributing information of interest to specialist working groups and other members of their section, for initiating action as necessary, and preparing for and conducting their sectional meetings at Congresses.

Section 11 (Forestry Influences), under Dr. H. Storey of Washington, dealt with three main topics: management of forested watersheds for water supply (where stress was laid on the need for new measurement techniques and instrumentation), the role of forests and engineering structures in the control of floods and erosion (emphasizing the supplementary functions of biological and engineering methods) and shelterbelts, and ended with appointing working groups to initiate and co-ordinate work in each of these fields. Section 21 (Site Factors), under Prof. de Philippis of Florence, had forest typology, the influence of forest stands on the soil, and biological factors of forest regeneration as its main topics, and set up a joint working group with Section 25 in order to study what are the best criteria for assessing the quality of sites and the relationships between environmental factors and the potential productivity of sites. In Section 22 (Forest Plants) under Dr. C. Syrach Larsen of Hørsholm, the chief topics discussed were seed production problems in forest trees and the growing of pines in the tropics and subtropics, a working group was formed on provenance research. This Section has hitherto concentrated on tree breeding, but is becoming increasingly interested in physiology. Dr. Leibundgut of Zurich presided over Section 23 (Silviculture), in which a great variety of subjects was discussed, notably silvicultural problems raised by the general unsaleability of small-dimensional timber—a topic of world-wide interest—for which a new working group was set up, silvicultural problems of tropical forests, soil amelioration and weed control in nurseries, and root formation and competition. This Section is also busy, in collaboration with the Bibliographical Section, on terminology in its field. Section 24 (Forest Protection), under Prof. A. Biraghi of Florence, dealt mainly with insect population dynamics—especially the influence of manuring of forest stands on the development of populations of noxious insects, about which there is some controversy, mycorrhiza research, international co-operation in forest disease research and in quarantine measures, and problems of smoke and industrial fumes damage to forest growth. It also created a fifth working group to study the important question of fire control.

Section 25 (Growth and Yield), under Prof. S. Firat of Istanbul, discussed mainly the use of climate site indices—concluding that these cannot by themselves afford an accurate guide to the quality class of individual forest sites and setting up a joint working group with Section 21 (see above), the use of electronic digital computers in forest research—recommending *inter alia* the compilation of a register of existing computer programmes of interest to foresters and an index of organizations and individuals that are actively using computers, increment determination in uneven-aged tropical forests (a matter of great present-day interest) and increment determination by borings—in both of which, it was agreed, investigations were not sufficiently advanced to permit anything but tentative conclusions. This Section has a permanent working group that advises the Union on all matters concerned with aerial photography, photo interpretation and photogrammetry, and maintains effective links with Commission 7 of the International Society of Photogrammetry, the report of this group was approved and its membership is being widened. The Section also recommended the formation by mathematical specialists of advisory groups for helping forest statisticians, both by suggesting improvements in current university curricula on statistical methods and by organizing the collection and distribution of case studies and other information of value for the statistical planning of forest research. Prof. J. Speer of Munich led Section 31 (Forest Economics), which formulated and recommended a special accounting system for forest commercial enterprises and a corpus of economic terms that could be used by all countries It also discussed the difficult topic of the measurement of forest work productivity with Section 32 (Operational Efficiency) the other main topics of which, under the chairmanship of Prof V Sundberg of Stockholm, were the effects of noise and vibration on the forest worker and the establishment of university courses in operational efficiency Section 41 (Mechanical Conversion), led by Prof J Campredon of Paris, discussed many aspects of this subject and decided to enlarge its field of study so as to embrace all forest products (this to be the new name of the Section), with three initial working groups for wood quality, behaviour of wood exposed to fire, and sawing and machining

Finally, on the initiative of Austria and Germany, the Union decided to create a new section, Section 11, on the History of Forestry, with Prof von Mantel (West Germany) as leader

The Bibliographical Section, which is actually a joint committee of the Food and Agriculture Organization and Union representatives, met as usual several days before the Congress, under the chairmanship of Prof E Saari of Helsinki It was concerned mainly with the prosecution of two long-term projects—further accurate translations of the classification now widely accepted in the world of forestry science (*The Oxford System of Decimal Classification for Forestry*, of which English, French, German and Spanish authorized editions have already appeared) and speeding up the production on cards of a basic forest terminology in the English language, as an essential preliminary to the multilingual terminology project, sponsored jointly by the Food and Agriculture Organization and the Union

Prof J Speer (West Germany) was elected to be president in succession to Mr Macdonald, whose term of office expires at the end of the year Dr V L Harper (United States) was elected vice-president Elections to the Permanent Committee (previous members in italics) were Prof N Anutschin (U S S R), *Prof. T Bunusevac* (Yugoslavia), Prof J. Campredon (France), Dr E Holmsgaard (Denmark), *Prof A Horky* (Austria), *Prof M. Kreutzinger* (Poland), Prof A de Phillipis (Italy), Dr D R Redmond (Canada), Dr H Shirley (United States), and Dr Saito (Japan), leaving two places to be filled by representatives from India and Latin America, not yet designated

The International Council met on the concluding day, and agreed to the revised statutes which take into account recent decisions of and developments in the Union, the major changes being to strengthen the position and powers of the enlarged Permanent Committee which is its executive body between Congresses A new class of member—associate member—has also been created and the organizing of the secretariat, following its recent relinquishment by the Food and Agriculture Organization, has been entrusted to the president himself

The Union accepted an invitation from Germany to hold the next Congress there After the Congress at Vienna, about 130 of the delegates took part in strenuous study-tours that lasted for 11 days of magnificent weather and covered the whole country One tour concentrated on silviculture and management, another on the many aspects of forest protection, and the third on mechanical developments in soil-cultivation and trenching, tree planting and tending, timber extraction and milling

F C Ford-Robertson

NUTRITION AND POULTRY

The Scottish Group of the Nutrition Society held its sixty-second meeting on September 30 in the College of Agriculture, University of Edinburgh It took the form of a symposium entitled "Nutrition and Poultry". As the chairman, Prof S J Watson (University of Edinburgh), pointed out in his opening remarks, since the subject was "Nutrition *and* Poultry" it was not confined to problems of poultry feeding but instead embraced broader aspects of nutrition in which work with poultry has contributed to knowledge

Dr W. P Blount (British Oil and Cake Mills, Ltd , London) opened the proceedings with a very thorough exposition of the use of birds as experimental animals He said that apart from some cage birds which have special uses, poultry were the most commonly chosen birds for laboratory work, and he emphasized the advantages of their cheapness, availability and ease of management Illustrating his talk with a series of informative slides, he described different forms of housing, from brooders for small groups of chicks to intensive houses for many thousands of adult birds He discussed optimal conditions of light, temperature and humidity, systems of feeding and ingredients of poultry diets. He concluded with a survey of the common diseases of poultry, and indicated that many of them could be controlled by good management and the judicious use of drugs such as antibiotics and coccidiostats

In the following paper Dr M E Coates (National Institute for Research in Dairying, Shinfield) dealt with problems of fundamental nutrition for which poultry have proved peculiarly suitable subjects, particularly in vitamin research The examples quoted ranged from Eijkman's classic observation of polyneuritis in hens fed on polished rice, which led to the discovery of vitamin B_1, to modern work on the isolation and function of vitamin B_{12}, a field in which work with poultry has played a major part The developing chick embryo was cited as a very suitable organism for investigating the biochemical role of nutrients, as evidenced by experiments on the metabolism of vitamin B_{12} and studies in tissue culture of the function of vitamin A She described how chicks can be relatively easily maintained in a germ-free state and are thus becoming increasingly important in investigations of the relation of the alimentary microflora to nutrition

Prof S Lepkovsky (University of California), who has used birds to study the nervous control of food intake, gave a fascinating dissertation on hunger, appetite and satiety He described the influence of the central nervous system through hunger- and satiety-centres in the hypothalamus He illustrated the psychological effects of these states amusingly and accurately in a series of lantern slides of "Hubert", an unfortunate character from a comic cartoon who was obliged to subsist on a low-calorie diet

It has become common practice to include in diets for livestock non-nutritional additives that increase growth-rate and level of production. In reviewing additives for poultry diets Dr. J H Taylor, (Cyanamid Products, Ltd , London) classified them into those that alter the microbial flora to the benefit of the host animal and those, largely having hormonal activity, that produce increases in growth or productivity by modification of metabolic processes The former class of compounds was of greater practical importance, and had the largest effect when the level of performance was poor Detectable quantities of some antibiotics given in the diet appeared in the serum If there was reason to suppose that the beneficial effect of the antibiotic was systemic it was desirable that blood-levels should be increased If, however, the response to an antibiotic was solely due to modification of the gut flora, such enhancement was unnecessary The hormonal food additives such as œstrogens and thyroid-active agents could be of use in increasing fat deposition and improving carcass quality, although there was some danger of residues in the tissues if œstrogens were given in the food

The final paper in the symposium was an entertaining account by Prof M F M Meiklejohn (University of Glasgow), speaking in his capacity as editor of *Scottish Birds*, of wild birds that have been used as food for man He began by reading from the *Book of Leviticus* the catalogue of birds that were prohibited as food by Mosaic law, and showed how nearly it corresponded to the list of birds customarily considered as unfit for consumption The choice of wild birds for human food depended on their palatability and the ease with which they could be captured In general, sea birds were less palatable than land birds, although there were instances of inhabitants of remote islands subsisting on some of the colonial nesting species Of the land birds, those that lived in flocks and hence were more easily caught in quantity were most frequently a source of human food Many of the traps and nets used to-day by ornithologists derived from the catching devices evolved long ago for the capture of wild birds for food Prof Meiklejohn posed a number of questions, which the audience attempted to answer, about the relation between the food of wild birds and their suitability for human consumption

The lively discussion that followed each of the papers fully justified the choice of subject for this symposium On this occasion at least, the more homely aspects of the domestic bird were overshadowed by its role in the field of nutritional science

M E COATES

THE EUROPEAN NUCLEAR ENERGY AGENCY

THE third report of the European Nuclear Energy Agency[*], presented to the Consultative Assembly of the Council of Europe by Prof S Balke on September 26, records substantial progress in the first joint undertakings Work on the Eurochemic site was inaugurated in July 1960 and the detailed pre-project for the plant was approved in June 1961 The Halden heavy-water reactor reached boiling in October 1960 with the first fuel charge of natural uranium, and installation of a second fuel charge of enriched uranium will permit a power of 20 MW to be reached before the end of the year joint operation of the reactor has been extended to the end of 1962 Construction of the *Dragon* high-temperature gas-cooled reactor began in April 1960 civil engineering work on the site is well advanced and supporting research and development are progressing in parallel

A group was set up in November 1960 to study the nuclear propulsion of ships, and a meeting of experts has been convened to determine the areas of nuclear research where particular need for international co-operation exists and the objectives and means of collaboration

The European–American Nuclear Data Committee, created in June 1959, reviews the measurement programmes of member countries, inventories the equipment available, and has compiled a list of requests for new measurements so as to facilitate collection of the necessary data It is also assisting countries which have only recently begun to work in this field, and the Agency, in July 1961, decided to establish a European system of supervision and emergency warning which involves the immediate notification of any abnormal increase in environmental radioactivity recorded in a member country A study-group on food irradiation was set up in January 1960 to examine the economic and technical possibilities of the application of food irradiation so as to harmonize national programmes and propose joint projects where appropriate International seminars for university teachers and technical executives were again organized in 1960 and 1961, and a specialized symposium on criticality control in nuclear industry at Karlsruhe was attended by one hundred specialists

The Agency has also undertaken the examination of regulatory, administrative and legislative provisions introduced by European countries to conform with the radiation protection norms adopted in 1959, and these norms are being revised, in liaison with Euratom and the International Atomic Energy Agency, to take account of the latest recommendations of the International Commission on Radiological Protection A Convention on Third Party Liability in the Field of Nuclear Energy, dated July 29, 1960, has been signed by sixteen members of the Organization for European Economic Co-operation The Agency also participates in the investigation of problems posed by the insurance of nuclear risks, and particularly the application of tax regulations governing technical reserves and insurance premiums to these risks A first set of regulations applicable to research or experimental reactors has been elaborated by the Control Bureau responsible, under the Agency's Steering Committee, for carrying out the Security Control Convention In addition, the Agency centralizes economic data bearing on the development of the nuclear industry, and the result of an investigation, published in 1960, predicted that nuclear power stations will provide less than 3 per cent of the capacity of the European electricity production in the coming five years and less than 10 per cent in fifteen years

The practical value of international co-operation in this field is fully established by the year's work, and the experience gained in co-ordinating scientific work shows that in this way the less advanced countries gain indispensable experience that they could not acquire by themselves, while the other countries also benefit. This effort should be continued on as wide a geographical basis as possible, for the value of the results is increased by the scope and variety of the means used and relative costs are reduced. The report emphasizes that this experience in nuclear research is valid in other scientific fields and that European scientific progress calls for a concentration of human, financial and industrial resources only attainable by international co-operation. Annexes to the report include a report on the possibilities of joint European action in nuclear propulsion of ships and L. Kowarski's report on new trends in atomic research and their international significance.

UNIVERSITY FINANCE IN BRITAIN: 1959–60

THE annual returns from universities and colleges in Great Britain* in receipt of Treasury grants for the academic year 1959–60, now covering twenty-one universities and three colleges, is prefaced by a somewhat longer general survey than last year, in which university expenditure on research and academic salaries is considered more particularly.

The University Grants Committee has already made a recommendation to the Chancellor of the Exchequer regarding the location of a fourth new university, in addition to those recommended in July 1960, to be located at Colchester, Canterbury and Coventry, but this location is not disclosed. The Committee considers that the establishment of any new universities beyond these four should wait on the report of the Committee on Higher Education, and meanwhile academic planning boards are being appointed for the Universities of Essex, Kent and Warwickshire. It is expected that the expansion proposed by existing Scottish universities will provide the additional places needed in Scotland by the early 'seventies. Apart from this, the University Grants Committee emphasizes the importance of the enthusiasm and interest of a sponsoring area in determining their decisions on the location of new universities, as well as the presence of industries and some local financial support, the supply of lodgings and the attractiveness of the location to academic staff.

Following Sir Arthur Rucker's review of the application by the universities of the procedures recommended by the Gater Committee, a Building Sub-Committee has been established under the chairmanship of Sir Keith Murray to advise the University Grants Committee on its procedures for assessing non-recurrent grants for building works. A sub-committee has also been set up to assess, and advise the Committee on, the proposals for development in Oriental, African, Slavonic and East European studies which come forward from the universities, and a committee has been appointed with Sir Edward Hale as chairman, to make a comparative study of the methods of teaching undergraduates now being used in the universities and colleges of Great Britain in the fields of arts and pure and applied science. The report was obviously written before the Chancellor of the Exchequer made his statement in July, and it remains to be seen whether and how far the provisional building programme which the Committee has agreed with each of the universities, in the light of the Chancellor's statement on January 25, 1961, for each of the four years 1962–65, will be affected. To meet the expansion to 170,000 students by the early 'seventies and make good the backlog of past years, a building programme of £175 million at 1960 costs is required. The Committee has no apprehensions on the quality of students expected in the next ten years; it stresses again the importance of halls of residence; it welcomes the attention which the universities are giving to their existing degree structure, including the postgraduate structure, and generally it is impressed and encouraged by the attitude of the universities to the projected expansion.

The report records a solution to the question of assistance for St. David's College, Lampeter, by association with the University College of South Wales and Monmouthshire, which will assume sponsorship for St. David's for a trial period of ten years, during which, from August 1, 1961, the University Grants Committee will consider applications for recurrent and non-recurrent grants.

The number of full-time students in British universities again increased, to 104,009, compared with 100,204 in 1958–59, and statistics collected in October 1960 show a university population of more than 106,000. There were 6,443 full-time and 2,400 part-time students from overseas within the British Commonwealth, and 4,208 full-time and 2,068 part-time students from foreign countries. Of full-time men students 36·8 per cent were in arts, 24·7 per cent in pure science, 19·7 per cent in technology, and 11·9 per cent in medicine; these figures compare with 36·8, 24·2, 19·5 and 12·5, respectively, in 1958–59. For full-time women students the corresponding figures for 1959–60 are 62·0, 21·1, 1·3 and 11·8, respectively, and for 1958–59, 62·6, 20·7, 1·0 and 11·9. Full-time advanced students of pure science numbered 4,512 (34·5 per cent), of technology, 2,442 (18·7 per cent), and of medicine, 1,052 (8·1 per cent); 3,585 students were taking postgraduate courses in teacher training.

Of the full-time students, 83,083 were reading for a first degree, 3,605 for a first diploma, and 16,649 were engaged in research or other advanced work; the corresponding figures for 1958–59 were 80,805, 3,928 and 14,839, respectively. Of the new full-time students, 25·2 per cent were in pure science, 16·0 per cent in technology and 9·0 per cent in medicine; in 1958–59 the corresponding figures were 24·1, 16·2 and 8·9 per cent, respectively. Of all full-time students, 76·0 per cent were men and 24·0 per cent women, a proportion practically unchanged from 1938–39, when the corresponding percentages were 76·7 and 23·3; 17·2 per cent were at the Universities of Oxford and Cambridge, 20·9 per cent at the University of London, 39·1 per cent at other universities and university colleges in England, 5·9 per cent in Wales and 16·9 per cent at Scottish universities. The proportion of full-time students residing in colleges or halls of residence was 27·0 per cent, compared with 26 6 per cent in 1958–59, 50·3 per cent were in lodgings and 22 7 per cent at home, but these proportions vary widely between men and women and between institutions

* University Grants Committee. Returns from Universities and Colleges in receipt of Treasury Grant, Academic Year 1959–1960. Pp. 76. (Cmnd. 1489.) (London: H.M.S.O., 1961.) 4s. 6d. net.

The proportion of assisted students was 82 4 per cent, compared with 80 5 per cent in 1958–59 and 71 9 per cent in 1953–54, ranging from 93 6 per cent in Wales, 89 0 per cent in English universities, excluding those at Oxford, Cambridge and London, to 73 4 per cent for Scotland Full-time teaching and research staff increased to 11,474 (10,823 in 1958–59) and 25 6 per cent are now in pure science, 15 0 per cent in technology and 17 3 per cent in medicine

Of the recurrent income of £59,800,092 (£52,273,306 in 1958–59), £43,170,107 was from Parliamentary grants (72 2 per cent), £5,990,466 from fees (10 per cent), £1,731,106 (2 9 per cent) from endowments, £1,533,673 (2 6 per cent) from local authority grants, £451,328 from donations and subscriptions, and £4,730,590 from payments for research Non-recurrent Treasury grants amounted to £19,852,747, an increase of £3,298,264 on the previous year, and of this, £13,839,308 was spent on building work, £1,914,375 on professional fees, £2,966,333 on furniture and equipment and £1,132,731 on site and property purchases Of the recurrent expenditure of £58,505,072—an increase of £3,978,797 on that for the period 1958–59—6 8 per cent was spent on administration, 44 0 per cent on salaries and superannuation of teaching staff, 11 1 per cent on departmental wages, 13 9 per cent on departmental and laboratory maintenance, 3 6 per cent on repairs and maintenance of buildings and 9 7 per cent on rates, insurance, heat, light, etc Expenditure on libraries, at £2,350,294, remained at 4 0 per cent of the total

HEALTH SERVICES IN SMALL FACTORIES

A CONFERENCE on "Health Services in Small Factories" was convened jointly by the World Health Organization Regional Office for Europe and the International Labour Organization at Dun Laoghaire, Dublin, Ireland, during May 2–16 (*WHO Chronicle*, 15, No. 9 , 1961) The forty participants in the conference included medical officers, officials from Ministries of Labour, and representatives of employers' and workers' organizations from more than twenty countries

Between 80 and 90 per cent of factories in most European countries employ less than 100 workers Of the 220,000 factories in the United Kingdom, 150,000 employ 10 or fewer workers ; more than a million people work in factories employing 25 or less, the number of such factories having nearly doubled in the past twenty-five years. In Italy, 95 per cent of industrial plants have less than 100 workers, in Switzerland 90 per cent, in Belgium 96 per cent, in Denmark 99 per cent, and in Sweden 92 per cent

While the problem of providing health services in large factories in Europe is well on the way to solution even though different methods are used in different countries, the smaller factories in most countries of Europe do not have health services on or near their premises The risks to which their workers are exposed are certainly not less than in the larger factories and in many cases are greater, since the working environment in terms of atmosphere, ventilation and layout is considerably poorer

Instruction in special hazards and supervision and training in handling dangerous materials, such as toxic chemicals or radioactive isotopes, are less efficient as a rule than in large factories While periodic medical examinations are compulsory for workers in certain dangerous trades, there are usually no medical facilities within the factory beyond a first-aid box—the foreman is often in charge of this, but he is usually untrained in health matters

There was general agreement among the participants in the conference that the provision of health services to these small undertakings is a real and urgent need, but there was less agreement about how to provide them Among the difficulties are the diversity and dispersion of factories, which may be scattered over considerable distances. It is feasible for a doctor to provide health care for 3,000 workers in one factory, but not for thirty factories each with 100 workers The cost of an autonomous health service is prohibitive for the small employer, and health hazards are often not understood or appreciated by employers and employees

The conference discussed schemes now being tried out in various parts of Europe to provide health services for small factories Four main tendencies are discernible

In Czechoslovakia and in eastern Europe as a whole, these occupational health services are provided as part of a general programme of health protection covering both curative and preventive medicine and organized by the State

In France, the Ministry of Labour is responsible for implementing general regulations on hygiene and security Employers are obliged to set up health services which, for the majority of small factories, take the form of inter-factory services The responsibilities of the physicians in these services are, in principle, the same as those of all industrial medical officers, that is, they are entrusted with preventive medicine, treatment being provided only in emergencies and for accidents

In Italy, health services in small factories are mainly the concern of the National Institute for the Prevention of Accidents, which has some thirty branches scattered throughout the country

In the Netherlands, the United Kingdom and Scandinavia, inter-factory occupational health services are provided on a voluntary basis, generally by means of a non-profit-making body on which doctors. employers and workers are represented. Organizations of this type show a tendency to grow in size and popularity as new factories join the service, and to extend to other areas Their role is mainly preventive , but in some cases, they provide treatment also

In a separate statement, the employers' representatives attending the Conference declared that, while agreeing that medical services in small factories should essentially be preventive, they nevertheless felt that these services should be encouraged to provide other treatment as well as emergency treatment The advantages to be gained are a more efficient use of man-power, an increase in production (since workers would not lose so much time visiting hospitals for treatment) and improved morale They stressed their opinion that such services should be organized on a voluntary basis

The representatives of the workers' organizations welcomed the important developments now taking place in the field of health supervision for their members, though many of them considered that progress in this field was still too slow It was their opinion that, by accepting the goal of occupational health services for all workers, the International Labour Organisation has opened an important chapter in the history of occupational health

UNIVERSITY OF SUSSEX

THE first prospectus* of the University of Sussex describes the origins of the University since it was first promulgated in 1911, the way in which it has been constituted, proposed developments and the kind of administrative and teaching and research arrangements which are being made for students

Courses leading to degrees in the Faculty of Arts and Social Studies will be organized and pursued in a a different way from that followed in other British universities The Faculty will be divided not into departments concerned with particular academic disciplines but into schools of study where different specialisms will be studied in relation to each other

In 1962–63 there will be three such schools—the School of Social Studies, the School of English and American Studies, and the School of European Studies A School of Afro-Asian Studies will follow later. Each School will have a dean at its head In addition, there will be professors and lecturers in particular subjects The schools will not be super-departments, and the same subject may be studied in more than one school

Details of the science curriculum are still under consideration It is intended to provide degree courses which will prepare students not only for careers as professional scientists, in the academic world, in industry, and in Government scientific establishments, but also for careers as teachers, and in industrial, commercial and public administration There will be a three-year course in natural science, leading to a classified honours degree During this course students will study three subjects chosen from pure mathematics, applied mathematics, physics, chemistry, and biology In addition, the curriculum will require some study (which will be examined) of the history of science and of the impact of science on society

For a limited number of selected students, there will be a second honours course lasting a year, in which one science only will be studied, and a successful candidate will be awarded classified honours in that subject The student who has completed this further course will thus have a specialized knowledge of a single science, and some understanding of the social sciences

There will also be a course lasting three years in engineering science This will be a general course, it is not intended to provide specialized courses in civil, mechanical or electrical engineering

During the years 1962–63 and 1963–64, only the subjects mathematics (pure and applied), physics and chemistry will be offered It is hoped to begin courses in engineering in 1964 and in biology in 1965.

METABOLISM OF THE HUMAN RED BLOOD CELL

SOME aspects of the metabolism of free fatty acids by the human red blood cell *in vivo* have been studied by Dr. D Mendelsohn of the Department of Pathology and Microbiology, University of the Witwatersrand, Johannesburg (*S. Afric J. Med Sci*, 20, Nos. 1 and 2, July 1961) Following the oral ingestion of glucose by a normal subject, an increase in erythrocyte-free fatty acid concentration occurs, reaching a maximum in 1–1½ hr In contrast, the diabetic patient shows a much smaller rise in red cell-free fatty acid during a glucose tolerance test, in many diabetic cases no increase could be detected at all This defect in the diabetic erythrocyte could be corrected by the intravenous administration of insulin during the performance of a carbohydrate tolerance test

Although the findings do not permit any definite conclusions to be drawn, it is suggested that the human red blood cell is able to synthesize lipid from carbohydrate *in vivo* This faculty seems to be impaired in the human diabetic erythrocyte.

Mendelsohn has also examined the interrelationships of carbohydrate and lipid metabolism in the human erythrocyte *in vitro*, all the findings observed when investigating the metabolism of lipids by the human red blood cell *in vivo* have been reproduced *in vitro* The results of the investigation suggest that under certain *in vitro* conditions, that is, in a phosphate buffer containing glucose and brilliant cresyl blue or methylene blue, the mature human red blood cell is able to synthesize fat from carbohydrate Any exchange of fat between red cell and serum which might have been expected to cause a rise in erythrocyte lipid-levels has been eliminated by incubating the cells in phosphate buffer instead of serum. The fact that normal red cells showed an increase in total esterified fatty acid together with free fatty acid indicates that the rise in cell-free fatty acid was not due to lipolysis of complex lipids with subsequent release of fatty acids

A much less noticeable rise in the level of free fatty acids was apparent in the erythrocyte of an insulin-deprived diabetic patient when compared with a normal patient Addition of insulin to the diabetic red cell suspension corrected this deficiency. It is suggested that under the *in vitro* conditions described, the mature human erythrocyte appears to be able to synthesize fat from carbohydrate whereas in the diabetic red cell this faculty is markedly impaired Mendelsohn has also examined some of the mechanisms which might be responsible for the abnormal behaviour of the diabetic erythrocyte

STUDENT MENTAL HEALTH

IF one asks an examiner of the old-fashioned, bluff, extraverted type why students fail in their examinations he will possibly reply "Because they are insufficiently prepared" No doubt he will be content to leave it at that, but if one continues the Socratic questioning and demands: "Why are they insufficiently prepared?" one will be told "Because they haven't worked enough" But this is not the complete answer, even supposing that one is told that their lack of work depends on a poor personality, laziness, or something of the sort.

These students who pose such problems are, as Dr Malleson pointed out at a conference on the mental health of students recently held in London*, those who have surmounted the difficult hurdles of the 'eleven plus', the Common Entrance, the General Certificate of Education examinations, and so on in the past. Why have they failed at the university?

The papers read at the conference suggest that there is no simple answer Although the student may have been successful at school, there are psychological difficulties associated with university life which may interfere with his work These range from home-sickness, if he lives in a hostel, or domestic unrest associated with parental quarrelling, if he lives at home to such grave psychological illnesses as schizophrenia, depression and the severe crippling neuroses.

Student failure may mean that a valuable young man gives up further education and takes up work inferior to his intellectual capacity It means, moreover, a great deal of expense to the nation It is estimated that a student costs about £700 a year to educate at a university If he gives up his academic career, as most students that fail do, after a year and a half, he has wasted at least a thousand pounds of public money When one considers the number of students the loss is potentially enormous

What is to be done about it? The answer lies, to some extent, in the work of the psychiatric advisers, who have the opportunity of examining students complaining of psychological symptoms. Many universities have such a unit and, as Dr Malleson emphasizes, if only four students a year are saved from giving up their academic careers in a year the adviser has earned his keep

Such an advisory unit is not primarily to treat nervous or mental illness, although one of its functions is early diagnosis, but to help the much larger number of students to overcome the usual adolescent difficulties Among those who complain of comparative trivialities the more sinister illnesses are found and even these, if discovered early, can sometimes be helped

The time has passed when students should be thrown ruthlessly into university life to sink or swim Such a policy may have sounded bold and manly, but many young men with otherwise a fine intellectual future have sunk, have worried over a triviality until they have broken down or taken their lives uselessly

Probably all those who are student advisers will agree that we do not know everything regarding the problems of academic life It is one of the advantages of an advisory unit that there is an enormous amount of material for research purposes, and, since the student is a picked man, derived from an intellectual *élite* Ultimately this work should throw a valuable light not only on student problems but also on mental health in general.

TRAWL FISHING IN THE TROPICAL ATLANTIC

Catch-rates and Composition

IT is notoriously difficult to assess relative productivity between trawl fisheries in different parts of the world because of the inherent differences in fishing power of the vessels operating each fishery Though it may be possible[1] to apply factors to convert the catch-rates of vessels of similar type, but of different size, to a standard form, this is generally only practicable within a limited geographical area The investigations of the Colonial Office vessel, *Cape St Mary,* off West Africa in 1952–57 and off South America in 1957–58, working with the same officers and gear on both sides of the Atlantic, offer an opportunity to compare the standing crop, in terms of catch-rate, of the demersal fish of the two areas Mitchell and McConnell[2] have described their investigations off Georgetown on the Guiana coast, and an account of the work off West Africa is now in preparation[3]. Salzen[4] has described some early results from Ghana with the same vessel, though with a different crew

The *Cape St Mary* was a 100-ft (between perpendiculars) steel trawler of rather typical North Sea design, of 238 gross tons and with 385-h p Diesel engine; details of her construction and gear are given in ref. 2 The trawls, in both areas, were of the Peter Carey type, 72 ft on the head-rope, and were normally worked with 25-fathom bridles

In the silty water and on the muddy deposits of those parts of the tropical Atlantic coast-line where there is heavy run-off of surface water from the land, there are few, if any, reef corals, and the ground is suitable for trawling; the demersal fish fauna is superficially similar on both coasts, comprising a large number of species, relative to temperate faunas, principally of Sciaenidae, Drepanidae, Pristipomatidae, Ariidae and Cynoglossidae, off West Africa, and of Sciaenidae, Pomadasydae, Gerridae and Ariidae off British Guiana On harder, sandy deposits the fauna comprises principally Sparidae, Lethrinidae and Lutjanidae off West Africa, and Serranidae and Lutjanidae off British Guiana However, the percentage composition of the catch is rather different off West Africa and off that part of South America (Table 1) which was investigated

There appears to be a much greater dominance of Sciaenidae in the British Guiana catches than in those

Table 1 Percentage Composition of Commercial Landings at Four Tropical West African Ports, from Various Sources, and of the *Cape St Mary* Landings at Georgetown, British Guiana

	Freetown	Abidjan	Takoradi	Lagos	Georgetown
Sciaenidae	34	21	44	25	67
Polynemidae	15	14	13	14	<1
Drepanidae (or Ephippidae	14	3	3	2	<1
Ariidae	11	2	—	14	4
Trygonidae	2	5	18	8	<1

from the African equatorial regions (Table 1) of comparable latitudes In this respect the Guianian fisheries appear to resemble more closely those of Mauretania and Angola, to the north and south of the African equatorial zone, where a single species (*Sciaena aquila*) dominates the landings, the more so since a single species (*Micropogon furnieri*) constituted up to 43 per cent of the total landings in Guiana.

In the final analysis of the catch-rates of the *Cape St. Mary* off West Africa[3], it was convenient to divide the data according to the fauna comprising each catch a Sciaenid fauna on soft deposits down to the level of the thermocline at about 55–65 m , a Sparid fauna on sand and shell-sand down to 90–110 m , and on mud between the thermocline and 110 m ; and a deep fauna, mainly of small, useless species, from 110 to 450 m , in which elements of the semi-abyssal continental slope fauna occurred Results in ref 2 are expressed in relation to deposit and depth but can readily be re-arranged to conform to the West African results, since a similar division of the fauna by deposits was recognized in that work

Table 2 Catch-rates (kgm /hr) of the *Cape St Mary* on Four Sectors of the West African Continental Shelf between 13° W and 17° W and on the South American Continental Shelf between 7° N and 8° N

	Sulima	Freetown	Conakry	Gambia	Georgetown
Sciaenids, etc	183	195	295	178	187
Sparids, or Serranids, etc	21	53	53	130	59
Deep fauna	14	—	43	90	7 5

The results (Table 2) show that the catch-rates off West Africa and South America are very similar, with a single significant anomaly; this is the high catch-rate of snapper off Gambia This region lies at the northern extremity of the equatorial zone on the West African continental shelf, near the limit of the tropical Sciaenid fauna and is characterized by a rich fishery for large snappers (*Dentex*, *Lethrinus*, etc) which, furthermore, extends much deeper—at least to the continental edge—than does the tropical Sparid fauna farther to the south A similar situation occurs at the southern end of the equatorial region in West Africa, to the South of Cape Lopez

Preliminary Bionomic Data from West African Fisheries

The determination of bionomic parameters in tropical fisheries is a matter of some difficulty, due particularly to the lack of seasonal or periodic changes in the environment, which renders useless many of the classical techniques in temperate and boreal seas[5] It has been shown[6] that demersal fish off Sierra Leone have, in general, no periodic cycle of feeding activity during the year, and it is known from general fisheries investigations there that many species are reproductively active throughout the year, juveniles of a few centimetres long being taken in the trawl debris in most months

However, recent investigations at Freetown[3] have shown that some species—fortunately including some of the more important commercial species—do, in fact, have a period of peak breeding activity which appears to have an annual periodicity, it has been possible to use the annual peak recruitment to the trawl catches of juvenile fish, and their subsequent growth, to determine rates of growth and mortality, using Petersen's technique

This evidence is derived from the inspection of the monthly length frequency distributions taken from trawling data—from commercial, exploratory and experimental trawling, the technique depends for its success on a number of factors that a single population can be sampled monthly, or more frequently, over a period of years, that the samples should be taken with a very small-meshed net so that the 50 per cent selection point of the net falls on fish of not more than six months old, that the juveniles should be present on the same grounds as the adults, without ecological separation and, finally, that there should be no significant difference in size between the sexes It appears that Sciaenidae and Drepanidae are the most likely families to fulfil all these requirements, and give the most satisfactory estimates of growth- and mortality-rates of the species investigated.

The results obtained for eight demersal species are set out in Table 3 in terms of length-for-age data

Table 3 Length-for-age Data, Lengths expressed as Total Length (Snout to Tip of Longest Caudal) in cm
Doubtful estimates in parenthesis

	I	II	III	IV	V	VI
Pseudotolithus elongatus	15 0	24 5	31 5	36 0	39 2	41 2
Pseudotolithus senegalensis	(15 0)	(28 0)	(42 0)	—	—	—
Drepane africana	16 0	23 0	25 5	—	—	—
Chaetodipterus lippei	15 5	24 0	—	—	—	—
Galeoides decadactylus	11 0	19 1	26 3	34 0	—	—
Pentanemus quinquarius	8 5	15 5	20 5	31 0	—	—
Pagrus ehrenbergi	(18 0)	(32 0)	—	—	—	—
Pristipoma jubelini	(15 0)	(22 0)	(30 0)	—	—	—

In a single species, *Pseudotolithus elongatus* (=*Corvina nigrita*), the data sufficed for a more detailed analysis than is included in Table 3 This is an abundant species in the estuarine and inshore catches, and the monthly length frequency distributions showed very satisfactory progression of peaks, month by month There was an annual peak of recruitment to the catches in June and July of small fish about 5 cm long which appeared to be the result of a spawning peak during the dry season at the turn of the year, confirmed by evidence from the gonadial cycle

From an investigation of the length/weight relationship of the species it is possible to derive an estimate of both relative and instantaneous growth in weight, and this is shown in Table 4

Table 4 *Pseudotolithus elongatus*, Growth in Length and Weight (h = relative, g = instantaneous growth in weight)

Year	Length (cm)	Weight (gm)	h	g
I	15 0	22 0	—	—
II	24 5	109 0	3 95	1 60
III	31 5	222 0	1 03	0 71
IV	36 0	337 0	0 52	0 42
V	39 2	403 0	0 19	0 17
VI	41 2	439 0	0 09	0 09

From dissections of the length frequency distributions of a large sample taken in November 1959, with a very fine-meshed net, it was possible to make an estimate of the relative numbers of individuals in

Table 5 *Pseudotolithus elongatus*, INSTANTANEOUS MORTALITY-RATE (i), ANNUAL MORTALITY-RATE (*a*), AND ANNUAL SURVIVAL-RATE (*S*), BIOMASS IN KGM OF THE SURVIVORS OF 1,000 FISH AT YEAR I (*P*)

Year	Log $n - \log n+1$	*i*	*a*	*S*	*P*
I	—	—	—	—	11 5
II	0 89	2 049	0 87	0 13	12 9
III	0 63	1 450	0 76	0 24	12 1
IV	0 63	1 450	0 76	0 24	2 2
V	0 43	0 990	0 62	0 38	1 0

each year-class and from these estimates, using Ricker's exponential tables[7] to make an estimate of mortality-rates These are shown in Table 5

From these estimations of mortality and from the length/weight relationship it is possible to estimate the relative biomass of the survivors year by year of a single-year class (Table 5) It is clear that in this species the relative weight contributed to the population by fish of more than 3 yr old is relatively very small, and it is clearly desirable that exploitation should begin before this time In fact, an estimate was made of the composition of the commercial landings at Freetown of this species and showed that 97·8 per cent of the individual fish landed were in their second or third year of life, and only 1·9 per cent were older fish.

In general, the tropical West African demersal fisheries appear to depend on only a relatively small number of year-classes of the constituent species, and this fact may be expected to have important consequences in any management policy—variations in the brood-strength of a species from year to year, for example, may be expected to have a far greater effect on the availability of a fish than is the case in a cold-water species, where the landings may depend on 10 or 20 yr -classes—and this may, in part, be an explanation of the puzzling fluctuations in abundance which are so characteristic of fisheries in this part of the world

The evidence on which these data are based will be published in full in the Colonial Office Fisheries Publications in due course

A NEW APPLICATION OF THE FARADAY MAGNETO-OPTICAL EFFECT FOR DIAGNOSTIC MEASUREMENTS OF TRANSIENT MAGNETIC FIELDS

By R. D. MEDFORD, W. H. W. FLETCHER, J. D. HERBERT and A. L T POWELL

Atomic Weapons Research Establishment, Foulness, Southend on Sea

EXTENSIVE use has been made of high-speed photography in plasma research but only to record plasma geometry, brightness, and the presence of instabilities and shock-waves We now describe a new technique for recording time variations in a longitudinal magnetic field which makes use of the Faraday magneto-optical effect, uses simple inexpensive apparatus and is easily incorporated into experiments already using streak camera observations

In an earlier paper[1] we described methods for superimposing streak (distance-time) and optical interference fringe photographs on the same emulsion By combining this and the new technique it should be possible to determine geometry, space-time distribution of electron number density in a high-density plasma (about 10^{17} cm $^{-3}$), and line-integrated variations of magnetic field along the line of sight with one streak camera

The magnetic field inside a plasma is usually determined from magnetic probe readings, but such readings are limited, since the physical presence of the probe introduces impurities and results in a perturbation of the plasma Even when the probe readings are only taken as valid up to the time when the plasma hits the probe, the problems of providing screening against radiation and protecting the recording oscilloscope from extraneous Earth currents is formidable The lifetime of plasma probes is also short

An interesting technique has been described in ref 2, it provides an independent method of measuring the longitudinal magnetic field inside a plasma without inserting probes and also gives the electron density But the method is only applicable to plasmas having a sufficiently low electron density to give a frequency below the propagating microwave frequeney and a magnetic field strength sufficiently large to give a measurable ratio of electron Larmor frequency to propagating frequency (w_L/w) In our experiments we work in the optical region with wave-lengths of 5×10^{-5} cm and magnetic fields of about 10^4 œrsted This means that we cannot use the Consoli–Dagai technique, since $(w_L/w) \simeq 10^{-5}$ However, this low ratio of (w_L/w) means that the electron density can be more accurately determined from the optical fringe pattern[3] and when the electron density distribution is known it is relatively easy to compute the associated magnetic field distribution inside the plasma[1] The magnetic field distribution determined in this way is, of course, a function of the magnetic field strength at the plasma boundary. which must be determined independently We determine the magnetic field at the boundary by making use of the Faraday magneto-optical effect in the walls of the plasma discharge tube

The experiment described here is our first experiment using the magneto-optical technique and is designed to measure the driving magnetic field inside a theta piece[4-6] The cylindrical discharge tube was made of extra dense flint glass, Chance number 70030, and has a Verdet's constant of about 0 09 where the Faraday effect is given by

$$\theta = rHL$$

Fig 1 Theta pinch at 1 mm ambient pressure

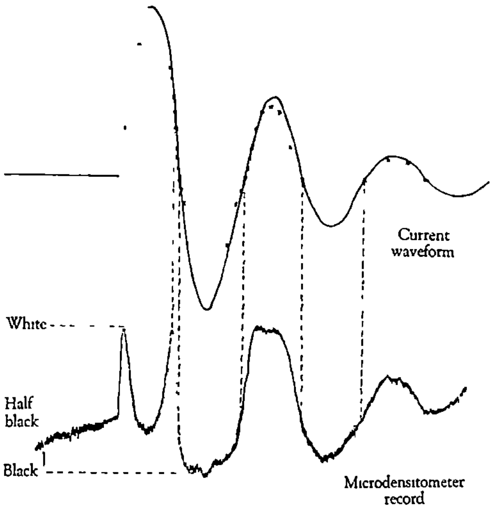

Fig 2 Theta pinch waveforms ×, from densitometer record

θ is the rotation of the plane of polarization in minutes, H is the strength of the magnetic field in œrsted directed along the optical axis; L is the path-length in cm , r is Verdet's constant and is given by the old classical theory[7] as

$$r = \frac{2\pi N e^3 w^2}{c^2 n(f - mw^2)^2}$$

where N is the number of electrons/unit volume, e and m are electron charge and mass, c is the speed of light, $2\pi(m/f)^{1/2}$ is the electron 'free period', w is the angular frequency of propagation, n is the refractive index in the absence of magnetic field

We have repeated the derivation of r allowing for the fact that H has a Fourier spectrum in the transient case and for an H component of angular frequency Ω we find that the frequency components of H modulate Verdet's constant so that w must be replaced everywhere by $(\Omega + w)$ Fortunately, in our experiment $(\Omega/w) \ll 1$ and Verdet's constant is not appreciably modulated

To measure the rotation of the plane of polarization we use a polarizer and an analyser to convert rotation into a change in intensity in the transmitted light Since the intensity is proportional to the square of the cosine of the angle between the plane of polarization of the light incident on the analyser and the plane of polarization for maximum transmission through the analyser, the analyser and polarizer are set with their planes of polarization at 45° to give maximum sensitivity and easy determination of magnetic field direction. The external driving field is derived from the rotation of light in the cylindrical wall The light is restricted to a sufficiently narrow band-width 5400–6400 Å by the polarizer At a suitable part of the camera sweep the light source is pulsed and a short time afterwards the theta pinch is initiated Light from the light source is also allowed to enter the camera without passing through the discharge tube to provide a light-intensity datum

Fig 1 shows a streak camera photograph of a theta pinch in deuterium, ambient pressure 1 mm of mercury fed by a 6 μF condenser charged to 9 kV Reading the photograph from top to bottom the first track is of light from the light source direct, the second track is of the polarized light passed through the discharge tube and shows clearly the modulation produced by the theta pinch magnetic field

Fig 2 shows the current in the theta piece monitored across a small series resistance together with a microdensitometer reading of the second track in Fig. 1 The vertical lines show the correlation between points of zero magnetic field and half-black light intensity points It will be noted that there is an extra half-black point corresponding to the large rotation produced by the high initial magnetic field To calibrate the apparatus the theta piece was evacuated and fed with current from a known condenser, thus providing a damped oscillation of the magnetic field

Fig 3 shows the associated streak photograph and Fig 4 the associated current and microdensitometer waveforms Once again there is an extra half-black point and two humps, which provide excellent self-calibration since they define a rotation of 45° in the discharge tube.

Using magnitudes of magnetic field defined by the damped current waveform and the first 45° point we find that the Verdet's constant for the discharge tube glass was 0 094 min /œrsted cm and using the calibration waveforms we have superimposed on the current waveform in Fig 2 the points obtained from the microdensitometer trace in Fig 2 It will be seen that the correlation is excellent and that the optical method fills in the initial rise that was too fast to be recorded by the current oscilloscope There was no need in this experiment to use the light-intensity datum trace in the interpretation of the microdensitometer traces shown in Figs 2 and 4, since we were fortunate in having a special high-intensity lamp developed by Dr. Gabriel of the Atomic Weapons

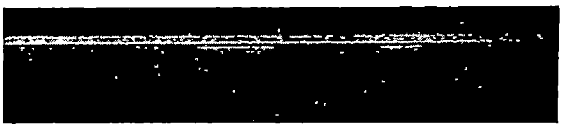

Fig 3 Calibration streak photograph

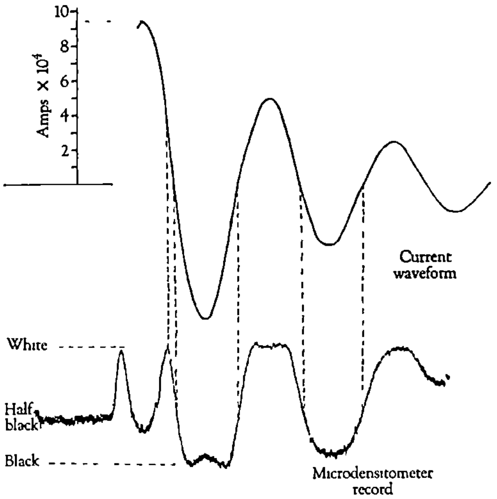

Fig 4 Calibration waveforms

Research Establishment[8] that gives a light pulse of about 10 µsec. duration which is remarkably constant However, we feel that the datum trace would have corrected for a lamp of inferior type. It is also fortuitous that the polarizer and analyser make the light a sufficiently narrow band for the purpose of the experiment and high-quality interference filters are not required

Fig 5 is a schematic diagram of our next experiment and is included to show how the technique may be extended to measure not only the driving magnetic field but also the trapped magnetic field in a theta pinch The diagram shows how the end windows of a pill-box type discharge tube can be used to measure the trapped field on the axis which is expected to have small divergence at the ends of the theta piece. The main feature of the optics is an iris diaphragm placed between a small supplementary lens and the exit lens feeding the light from the centre of the theta piece to the camera By controlling the diaphragm aperture the transmitted light through the centre will have a good 'signal-noise' for measurement of trapped field to be made even when the plasma fills the whole cross-section[1]

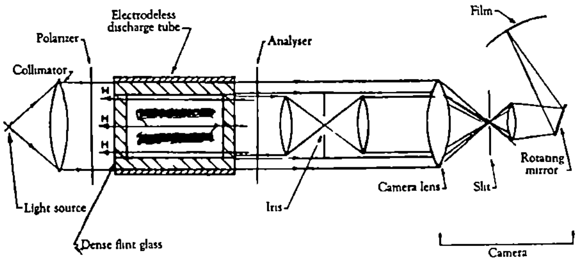

Fig 5 Proposed optical system

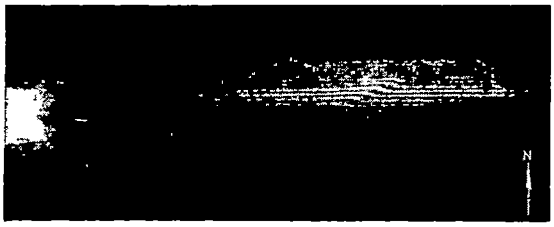

Fig 6 Streak-interferogram at 1 mm ambient pressure

Fig 6 is a streak camera record of a theta piece with interference fringes superimposed and is added for sake of completeness so that the reader can visualize a composite picture showing fringe shift and trapped and driving magnetic fields We wish to thank Beryl Richardson for her invaluable assistance in the experiment We are also indebted to Dr Gabriel for supplying the special light source and the Director of the Atomic Weapons Research Establishment for permission to publish this article

SOME PHYSICO-CHEMICAL PROPERTIES OF PARACRYSTALLINE SPHERULITES OF BIOLOGICAL ORIGIN

By Dr G T STEWART

Medical Research Council Laboratories, Carshalton, Surrey

THE occurrence of lipoid in a mesophase in certain mammalian tissues has already been reported[1] Matter in this form possesses paracrystalline or liquid crystalline properties whereby the molecular compactness and regular orientation, characteristic of a true crystal, is preserved when, in a given thermal range, liquid mobility is demonstrable There are theoretical reasons for believing[2] that a mesophase of this kind is ideally suited for protoplasmic structure, in the case of certain lipoid complexes, it has now been shown[3] that a mesophase with characteristic liquid crystalline properties exists, naturally, in specialized cells of the ovary, adrenal and other tissues, though not in depot fat; pathologically, a similar mesophase may be present in plasma lipoprotein and in the soft parts of atheromatous deposits in arteries Under experimental conditions, similar lipoid complexes can be produced by pulsating the lipoprotein fraction against normal arterial intima at physiological pressures[4]

Known for years to physicists and physical chemists[5], the mesomorphic form of matter has not been extensively studied in biological material, nor in relation to disease The following report therefore describes further some of the properties of the spherulitic liquid crystals observed in various forms of lipoid mesophase in tissue

Material for study was obtained by making squashed preparations of the appropriate tissues in microscopic films, or, when bulkier yields were necessary, by homogenizing the tissue in water For general use, an abundant yield of paracrystalline substance was readily obtained by homogenizing segments of liver, taken by biopsy or at autopsy, from rabbits fed with 0 5–1 0 per cent cholesterol for three months or more From this homogenate, intracellular and cell-free lipoid were separated by centrifuging, and independently studied in aqueous or other suspensions More exact details of technique are described elsewhere[3], and paracrystalline substance has also been studied in lipæmic plasmas, resected atheromatous vessels in patients, corpora lutea in surgically excised ovaries, and other sources Examined in microscopic films under polarized light, fresh preparations of the tissues mentioned show abundant birefringent particles intra- and extracellularly including, in the soft lipoid components spherical droplets 0 5–2µ in diameter These anisotropic droplets (spherulites) have firm but not rigid, uniformly spherical outlines at 4–25° C , each droplet contains a polarization cross with arms parallel to the planes of polarization. When the film is rotated, the arms do not change direction or undergo extinction, when the analyser is rotated, the cross is extinguished at 180° intervals The sign of birefringence is positive and, with the polarizer only *in situ*, a faint interference pattern may still be seen These droplets are therefore liquid crystals of spherulitic structure, without surface attachments to the suspending liquid or, when intracellular, to the cytoplasm.

On a heated stage at 30°–37°, the spherulites tend to increase in size by limited confluence and are then deformed in outline when compressed; the polarization figure loses its symmetry but retains a roughly cruciate pattern and a positive sign of birefringence At 37°–42°, liquid flow is present, with birefringence, at higher temperatures, a true liquid, transparent, isotropic melt results From this, a mesophase with considerable liquid crystalline growth of spherulites and an orderly arrangement of polarization colours re-forms on cooling At 0° C or below, the spherulitic structure is destroyed, the degree of destruction being more or less proportional to the rate and intensity of cooling, placed for a few seconds in liquid nitrogen, the liquid crystals are instantaneously and permanently destroyed, with liberation of free cholesterol in amorphous or true crystalline form, true crystals of fatty acids and other indeterminate particles Individual spherulites show paracrystalline growth when kept for some hours in water or salt solutions, but not in glycerol They are destroyed by organic solvents and dehydration In white light, they are greenish and refractile, the larger spherulites may show a weak reaction with sudan dyes, when treated with benzpyrene[6], they show faint blue fluorescence in ultra-violet light

These properties of the spherulitic component of this lipoid mesophase indicate that the constituent molecules are radially arranged, unstable to changes in temperature, dehydration and organic solvents, but stable at 4°–37° and, in this state, penetrable by water and triglycerides. The spherulitic structure is, however, resistant to disruption by various other physical agencies, including ionic and non-ionic detergents, lipase, rat-liver esterase, trypsin and ultracentrifuging in salt solutions at 80,000g When subjected to ultrasonic vibrations (20 kc /s), no structural change can be detected in 30 sec but disintegration begins thereafter and is complete in 3–5 min. γ-Radiation up to 5 M rads from a cobalt-60 source produces no change nor does irradiation with 4-MeV. electrons from a linear accelerator.

It is known[7] that some of the lipoid in abnormal, hyperlipæmic plasma is resistant to the action of clearing factor, and this may also be related to the presence of a stable mesophase When heparin, or a comparable sulphated polysaccharide, is injected intravenously into a patient with essential hyperlipæmia (or a cholesterol-fed rabbit) with an abnormal, low-density β-lipoprotein plasma component, the classical clearing effect is often not obtained This anomaly is due to the abnormal β-lipoprotein which resists, or may even inhibit[8], the action of lipoprotein lipase, considered by some authorities to be the active clearing factor[9]. If the abnormal lipoprotein is then separated by centrifugal flotation from the uncleared plasma and examined at 22°–37° under polarized light, much of it is present in the form of a spherulitic mesophase, similar in properties to that already described in atheromatous and other tissues This abnormal lipoprotein complex can therefore exist within the plasma colloid as a mesophase, more stable than the chylomicron emulsion of normal lipæmia, and immune to one of the principal physiological clearing mechanisms This is the form of lipoprotein which, when pulsated against excised arterial segments, produces atheroma-like deposits in a similar lipoid mesophase[4] It is therefore possible that the presence in circulating blood of this form (S_f 12–20) of low-density lipoprotein is of direct causal importance in atherosclerosis.

Histochemical and chromatographic work[3] has shown that cholesterol esters and other lipids, as well as protein and water, are probably present in spherulites of the type described These constituents must therefore be linked in an amphiphilic system within a molecular structure which, at body temperature, is loosely radial and perhaps helical The physicochemical possibilities inherent in such systems have been made explicit in recent work[10,11] on phase-equilibria of soaps, water and sterols, it is highly probable that, in cytology as in physics, some of the particles which used to be called fatty micelles should now be regarded as paracrystalline complexes with this kind of structure which makes them amenable to incorporation in protoplasm while preserving the molecular orientation and penetrability to other lipoids and water, necessary for reactivity Apart from this functional aspect, the importance of a liquid crystalline system in polypeptide solutions[12], and of spherulitic texture in polyethylene fibres[13] suggests, by analogy, that the paracrystalline form may be equally essential as a structural mechanism in certain cells and tissues, especially where complex macromolecules of lipoprotein and steroids are involved

It is a basic property of liquid crystals that their molecules are held together by forces which, though complex, are weaker than those of true crystals. In the case of the liquid crystals described here, the weakness is revealed by the effects of temperature and organic solvents, but the bonds are remarkably resistant to agencies such as ionizing radiation, ultrasonic vibrations and lipolysis, whether by enzymes or detergents, which readily disrupt lipoid complexes in fine emulsions and cell membranes The implications of this peculiar stability, in terms of energy values, are beyond the scope of this article, but it is perhaps clear that a study of this question, coupled with a crystallographic analysis of structure, should be of value in solving a fundamental and largely unexplored problem in molecular biology

The irradiation experiments were carried out at the Research Laboratory of the United Kingdom Atomic Energy Authority at Wantage, Berks , in collaboration with Dr D B Powell

KINETICS OF REACTION OF THE DECOMPOSITION OF LEAD AZIDE

By Dr M. STAMMLER, J. E. ABEL and Dr R C LING
Picatinny Arsenal, Dover, New Jersey

It has been reported[1,2] that the decomposition of inorganic azides begins at the crystal surface and that the crystal is soon covered with a thin film of metal formed by the reaction

$$2MeN_3 \rightarrow 2Me + 3N_2 + X \text{ kcal } (Me = \text{metal ion})$$

This reaction has been investigated extensively in the case of silver azide Moskovich and Aleksandrovitch[3] reported the formation of lead atoms at active surface regions during the initial stage of decomposition of α-PbN_6 These lead atoms then act as crystallization centres and cause an autocatalytic acceleration of the decomposition which is accompanied by the accelerated formation of a second solid-phase Pb-PbN_6 We have investigated in detail the reaction kinetics involved in this decomposition of α-lead azide

In ref 4 the isothermal decomposition of α-lead azide at 150°, 175° and 200° C in air was described It was found that at those temperatures the decomposition goes through at least two phases One phase could be isolated and classified as a tetragonal deformed cubic structure but, unfortunately, the other phases could not be isolated According to the chemical analysis of the compound isolated, oxygen could be present only to a small extent These experiments did not show whether the oxygen of the air was important in the formation of these phases during the decomposition, and the question could then be raised as to whether they consisted of basic azides or other oxygen-containing compounds as had been reported in ref 5 These authors reported that basic lead azides have been prepared by hydrolysis of PbN_6 with water, by reaction of PbN_6 with sodium hydroxide, and by precipitating PbN_6 from lead salt solutions via the addition of a mixture of NaN_3 and sodium hydroxide Nine different basic lead azides, including three forms of PbN_6 xPbO, were identified using X-rays

X-ray work on phase 3. It has been mentioned[4] that during the isothermal decomposition of α-lead azide at 175° C in air the last stage of decomposition corresponds to a compound with an approximate formula of ($PbN_{2\ 5}(OH)_n$), herein called phase 3 (The nitrogen is probably present as azide nitrogen) Additional calculations show that some weak X-ray reflexions, which could not be indexed as cubic and which have been ascribed to impurities resulting from other decomposition phases, belong to the structure of phase 3 The crystal structure of this compound is more appropriately considered as a tetragonal deformed cubic lattice On this basis the following data have been calculated

cell dimensions, $a_0 = 12\ 25_4$ Å , $c_0 = 11\ 88_5$ Å , $c_0/a_0 = 0\ 9698$,
volume of the unit cell, $V_0 = 1784\ 66$ Å ^{3},
density (pycnometric) $d_p = 5\ 623$ gm /cm ^{3},
density (X-ray) $d_x = 5\ 633$ gm /cm ^{3}

Debye–Scherrer photographs and X-ray diffractograms of this compound showed the following systematic absences

(hkl) - - - - - absent except $h + k = 2n$
$(hk0)$ - - - - - absent except $h + k = 2n$
$(0kl)$
$(h0l)$ - - - - - absent except $k + 1 = 2n$
(hhl) - - - - - no conditions
$(h00)$ - - - - - no conditions

These extinction data make possible the assignment of the space-groups D_{3h}^{12}, $P4_2/nnm$ and D_{4h}^{7}, $P4/nmm$, with the first of these being the most probable During about thirty experiments this structure was observed within 16 0–16 8 per cent loss in weight of the samples This is approximately the range of homogeneity of this phase

It is interesting to note that phase 3 can also be formed by heating α-lead azide at higher temperatures for shorter periods of time For example, this compound was formed by heating α-lead azide at 360° C for 3 min Longer heating will result in a change in colour from yellow to orange and finally brown.

Decomposition in pure argon and oxygen atmospheres To investigate the influence of oxygen during the isothermal decomposition of lead azide, experiments using thermogravimetric techniques were carried out at 175° C in argon and oxygen While the decomposition in air with 40 per cent relative humidity led to an average of 16 4 per cent loss in weight, experiments in dried argon and oxygen resulted in a 12 per cent loss at the same temperature (Fig 1)

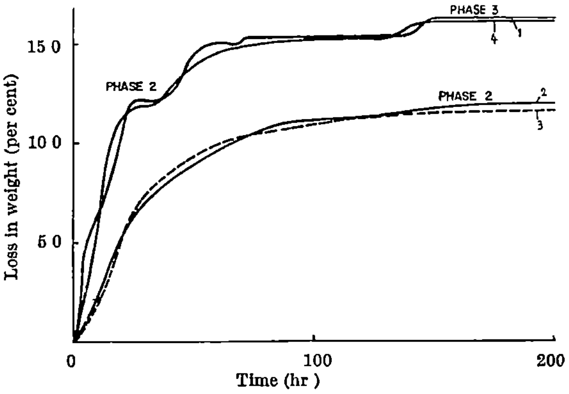

Fig 1 Decomposition curves of lead azide in air with 40 per cent relative humidity (1), in dried argon (2), oxygen (3), and argon saturated with moisture at 26° C (4)

It has been shown[4] that α-lead azide decomposes in air in several steps which must be considered as definite crystal phases During decomposition at 175° C the first step is reached when the sample has lost about 12 per cent in weight However, according to the shape of the curve up to this step, it is possible that there is more than one reaction mechanism involved Up to a 4 6 per cent loss in weight the slope of the curve, that is, the rate of evolution of nitrogen, is equal to 1 3 per cent/hr , whereas the rate of volatilization of nitrogen in the second stage, up to about 9 per cent loss in weight, is 0 36 per cent/hr and, up to 12 per cent loss in weight, about 0 5 per cent/hr These steps can be seen in Fig 1, which indicates a clear break in the curve at 4 6 per cent loss in weight which may be due to the formation of an intermediate state not shown in Fig 6

The decomposition does not follow this course if the experiment is run in dried argon and oxygen While the first step in air containing 40 per cent relative humidity occurs at 175° with 12 per cent loss in weight after about 30 hr. the same result was obtained in dried argon and oxygen after about 100 hr The decomposition in oxygen or argon follows a continuous curve and does not show the changes in the reaction-rate observed in air (Fig 1) However the X-ray diffraction patterns of the products formed in air at ambient conditions, in dried argon and in dry oxygen are the same This indicates that, until this stage of decomposition, oxygen does not affect the reaction It is very probable that the presence of moisture accelerates the decomposition reaction and causes at least a partial hydrolysis

It is believed that subsequent decomposition (greater than 12 per cent loss in weight) is only possible in the presence of moisture. On a weight basis, the residue corresponding to the 12 per cent loss in weight may be identified as phase 2, $\mathrm{PbN}_{3\,5}(\mathrm{OH})x$ This compound can be formed either by heating PbN_6 in air with moisture (relative humidity 40 per cent) at 175° C for 30 hr or by heating in oxygen or argon at the same temperature for 100 hr As expected, phase 2 formed by these three experiments showed identical X-ray diffractograms It is possible that even in the 'dried' argon and oxygen, traces of moisture are present which may contribute to the formation of his phase In Fig 2 the observed reflexions of this phase are compared with those of pure α-lead azide Phase 2 seems to have a higher symmetry than the original α-lead azide but a lower symmetry than phase 3

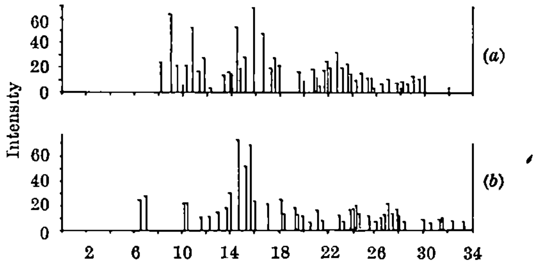

Fig 2. X-ray reflexions of (a) α-lead azide, (b) phase 2

Apparently moisture affects the rate of decomposition, but the manner in which it accomplishes this is not fully understood at the present time It is believed that small amounts of water vapour may hydrolyse the lead azide at elevated temperature[5] If layers of lead were formed during decomposition, one would expect different results because such lead, being very reactive, would immediately form lead oxide in the presence of oxygen Neither the reflexions of lead oxide nor those of metallic lead could be observed on the X-ray diffractograms of phase 2 obtained through decomposition in oxygen, argon or air The formation of phase 3 could not be achieved at the given temperatures in pure argon and oxygen and it was concluded that a relatively high moisture content is necessary for the formation of this phase (Phase 1, previously called α-phase[1], was observed only when heated at 150° C) However, phase 3 was also obtained when α-PbN_6 was heated in argon which had been bubbled through water at 26° C

Comparison of some properties of α-lead azide and phase 3 The ignition time of phase 3 was determined at several temperatures and compared with that of α-lead azide under the same conditions The apparatus used for these experiments is shown schematically in Fig 3

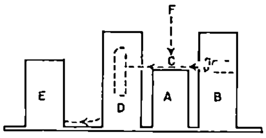

Fig 3 Apparatus for measuring time for ignition *A*, electrically heated plate, *B*, source of light, *C*, beam of light, *D*, photomultiplier tube, *E*, Hewlett–Packard timer, *F*, sample

The instrument consists essentially of a small electrically heated hot plate (*A*) with a centrally located iron-constantan thermocouple for determining its temperature and a photoelectric system for triggering the electronic timer A 1/16-in diameter light beam is focused across the centre of the hot plate (*A*) to a photomultiplier tube (*D*) When the hot plate is at the desired temperature, about 0 003 gm of sample is dropped through the light beam (*C*) on the plate The falling sample breaks the light beam and causes the photomultiplier tube to put out a pulse which starts the counter (*E*). The flash accompanying the ignition of the sample actuates the photomultiplier, which then stops the counter The time until ignition is determined to 0 001 sec and the temperature of the plate to ± 1° C

The results so obtained for phase 3 and α-lead azide are plotted as temperature versus induction-time curves in Fig 4 In both curves (4*a* and 4*b*) every point is the percentage fired out of twenty tests The standard deviation of this method is about ± 5 per cent An attempt was also made to calculate the activation energies of these compounds using the Semenov equation[7] and the plot of this is shown in Fig 4*b* The activation energies of phase 3 and PbN_6 were determined to be 80 and 100 kcal /mole, respectively It should be mentioned that these activation energies are only apparent activation energies[6]

According to these results the compound $\mathrm{PbN}_{2\,5}(\mathrm{OH})_n$ is less sensitive to ignition than the α-lead azide It was noted that below 450° C phase 3

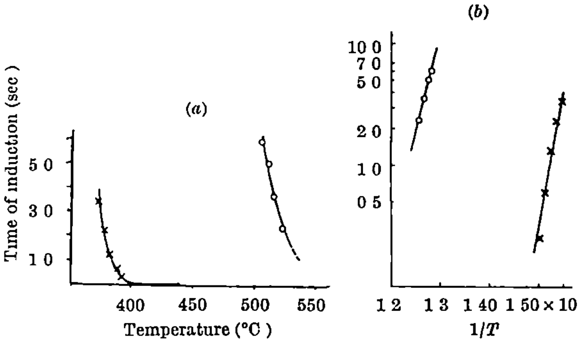

Fig 4 (*a*) Temperature against time of induction ×, α-lead azide, ○, phase 3 (*b*) time of induction against 1/*T* ×, α-lead azide with energy of activation 100 ± 20 k cal /mole, ○, phase 2 with energy of activation of 80 ± 20 k cal/mole was found to undergo slow decomposition, but no ignition was observed at this temperature On the other hand, the lowest ignition temperature for lead azide is about 370° C and its ignition time at 400° C is less than 0 1 sec

To test the electrical sensitivity of phase 3, small 1/4-in diameter plugs of insulating material were coated with a thin gold film to form an electrical bridge and a 0 06 gm pellet of sample was pressed at 3,000 lb /sq in on the gold film The resistance of the loaded plugs ranged from 1 to 3 ohms and their firing characteristics were determined by the discharge of a 1 μF condenser at varying voltages In Fig 5 percentage fired is plotted against the input voltage For comparison, the electrical sensitivity of lead azide is also included in Fig 5 It is apparent that although less sensitive than the untreated lead azide, phase 3 can still be considered as an electrically sensitive material

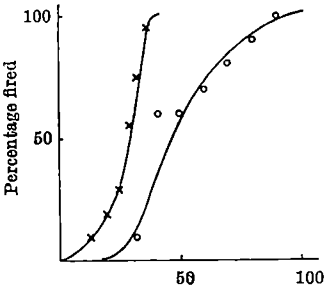

Fig 5 Electrical initiation of α-lead azide (×) and of phase 3 (○)

Investigations with infra-red The infra-red spectrum of phase 3 is slightly different from that of α-lead azide, although the main absorption band at 4 93μ occurs in both samples with the same intensity In Table 1 the observed absorption bands of α-lead azide and phase 3 are listed The pellets used for the infra-red analysis were prepared by pressing 200 mgm. KBr and 2 mgm of PbN_6 or $PbN_{2\ 5}(OH)_n$ at 15,000 lb /sq in The thickness of these pellets was approximately 1 mm

The absorption of both samples was most intense at about 5 0μ This band can best be ascribed to a stretching vibration of the N≡N triple bond As indicated in Table 1, only slight differences between the two samples could be observed so far as their infra-red spectra were concerned In the case of lead azide the most intense absorption band consists of two distinguishable peaks at 4 93μ and 5 05μ respectively, whereas with phase 3 there is only one peak which occurs at 4 95μ Another absorption band of lead azide with a weaker intensity was observed at 7·55μ due to the symmetrical vibration of the azide group In this region the decomposition product (phase 3) showed two absorption maxima at 7 15–7 20μ and 7 63μ The first band is probably due to the N=N double bond while the peak at 7 63μ is possibly caused by an OH bending vibration In the spectrum of both α-lead azide and its decomposition product, an absorption band at 2 95μ could be observed However, the intensity of this band in the spectrum of phase 3 was found to be twice the intensity of the lead azide peak This would suggest that hydrogen bonding is present in both cases Although the samples had been dried very carefully to remove all moisture and water, the spectra showed that this band (2 95μ) was still present It is very probable that the lead azide also contained a small amount of bonded water which could not be removed by the normal drying procedure and which might be considered as a stabilizer (through OH-bonding) of these compounds Apparently even heat treatment with decomposition of lead azide does not remove this water For future investigations it would be of interest to prepare lead azide without using water as a solvent, if possible. Another absorption band was observed in both samples at approximately 6 10–6 20μ which may be attributed to the N—H bond Again, the band due to phase 3 was twice as intense as that of untreated lead azide Finally, a weak absorption band which occurred in both samples with about the same intensity could be observed at 4 30–4 35μ This may be caused by hydrogen bonding in the condensed state One cannot, however, arrive at a final conclusion based on these results at the present moment, but more information may be forthcoming if lead azide can be prepared in a non-aqueous solution

Table 1 Infra-red Spectra

α-Lead azide (PbN_6)			(Phase 3) $PbN \sim 2\ 5\ (OH)_n$		
Absorption band	Int	Remarks	Absorption band	Int	Remarks
2 95μ (3,400 cm $^{-1}$)	4 5	OH bonding vibration	2 95μ (3,400 cm $^{-1}$)	9 3	OH bonding vibration
4 30–4 35μ (2,325–2,300 cm $^{-1}$)	2 0	hydrogen bond	4 30μ (2,325 cm $^{-1}$)	2 5	hydrogen bond
4 93μ (2,030 cm $^{-1}$	25 0	asymmetrical stretching of the azide group	4 95μ (2,030 cm $^{-1}$)	24 0	stretching vibration of the N≡N triple bond
5 05μ (1,920 cm $^{-1}$)	24 5				
6 10–6 20μ (1,640–1,610 cm $^{-1}$)	3 5	N—H bending vibration	6 10–6 20μ (1,640–1,610 cm $^{-1}$)	8 0	N—H bending vibration
			7 15–7 20μ (1,400–1,390 cm $^{-1}$)	9 0	N=N bond
7 55μ (1,325 cm $^{-1}$)	2 8	symmetrical stretching vibration of azide group			
			7 63μ 1,310 cm $^{-1}$	6 5	OH bending vibration
			14 75μ 678 cm $^{-1}$	5 0	not known

Conclusions Based on the results obtained thus far, it appears that the reaction mechanism during the thermal ignition of lead azide in air is dependent on the temperature and time to ignition. Ignition times of less than 0 5 sec have a single mechanism which probably goes through an activated state by which the required energy for a chain reaction is delivered (mechanism I, Fig 6) These activated centres have to reach a certain concentration in a short time-interval in order to deliver enough energy for ignition If, on the other hand, the temperature is not high enough to form this threshold concentration (there may also be a threshold temperature) the available energy cannot be supplied to cause the chain reaction and the decomposition will proceed slowly through

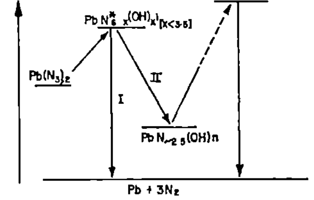

Fig 6 Kinetics of decomposition of lead azide

the different phases (mechanism II, Fig 6) It is possible, however, that within a certain range of temperature both mechanisms are competing with each other For the slow decomposition, a hydrolysis reaction is assumed since the presence of oxygen during this decomposition had no effect on the hydrolysis reaction

We thank Dr J. V R Kaufman for his interest and encouragement during the course of this work, Mr C Campbell for the thermogravimetric work, Mr J Campisi for the X-ray photographs, and Dr N Paraskevopoulos for the infra-red spectra

PROBABILITY DISTRIBUTION ANALYSER PROGRAMMED FOR NEUROPHYSIOLOGICAL RESEARCH

By Dr. W. R. LEVICK, Prof. P O. BISHOP and W. O. WILLIAMS

Brain Research Unit, Department of Physiology, University of Sydney

AND

Prof D. G. LAMPARD

Division of Electrotechnology, Commonwealth Scientific and Industrial Research Organization

THE sensory side of the nervous system is basically 'noisy'. Information supplied by sensory stimulation is transmitted through the brain as patterns of nerve impulses. In the absence of stimulation, however, the trains of nerve impulses do not subside completely but are replaced by a 'spontaneous' discharge which may be quite as striking as the information-rich pattern. It is perhaps surprising that so little attention has been given to an understanding of the nature of this spontaneous discharge There are, however, serious practical difficulties Superficially this discharge of nerve impulses appears to be without any pattern Apart from using devices which indicate the mean rate of the unit discharge, one must undertake a very large amount of tedious manual computational work to derive more comprehensive statistics and this has undoubtedly been responsible for the lack of interest in this phenomenon

Recently a probability distribution analyser was described[1] based on the Hutchinson and Scarrott pulse-height analyser, used extensively in nuclear physics It has been successfully applied to computational problems in the field of stochastic processes and noise We have now programmed this instrument to derive the frequency distribution of intervals between successive impulses of the spontaneous (and light-evoked) discharge of single units sampled at various points in the visual system The distribution is presented as an 'interval histogram' While this work was in progress other workers have independently derived similar statistics from the auditory system[2]

The probability analyser is basically a cathode ray tube electrostatic memory of 64 channels with 15 binary digit capacity a channel. The voltage applied to its input terminal is ordinarily sampled at a fixed (relatively slow) rate of 100/sec , counts being added to the channel corresponding to that input voltage Auxiliary circuitry was developed to convert the time-interval between successive impulses into a voltage proportional to that interval Suitable

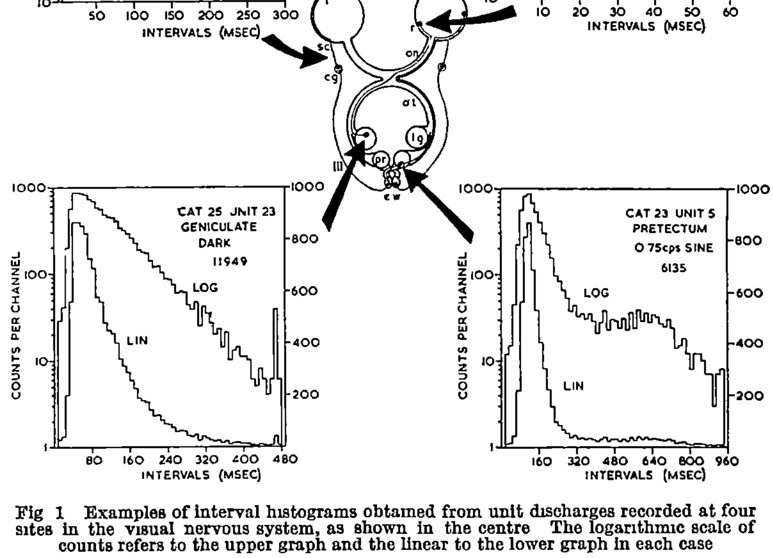

Fig 1 Examples of interval histograms obtained from unit discharges recorded at four sites in the visual nervous system, as shown in the centre The logarithmic scale of counts refers to the upper graph and the linear to the lower graph in each case

gating ensured that the analyser accepted not more than one sample of the voltage corresponding to any interval

Certain limitations of this arrangement were recognized Due to the fixed maximum sampling-rate of 100/sec , there was a probability that a sample would be missed whenever an interval in the discharge was 10 m sec or less The particular sample missed would correspond to the interval preceding the short interval If successive intervals are statistically independent, the missed samples will not affect the shape of the histogram obtained, but only scale down all channel counts by a constant factor, when sufficient intervals have been analysed to smooth out statistical fluctuations However, since there was no prior knowledge that successive intervals in the nerve discharges were statistically independent, we have excluded those units in which missed samples amounted to more than 1 per cent of the total number of intervals examined

The method has been successfully applied to unit activity recorded from four sites in the visual system of the cat retina, lateral geniculate nucleus, pretectal nucleus and short ciliary nerve Some examples of interval histograms obtained are shown in Fig 1 Of immediate interest is the remarkable dissimilarity of the distributions from different regions That of the retinal ganglion cell presented is of asymmetrical Gaussian type whereas the particular geniculate cell distribution seems best compared with a Poisson type On the other hand, the short ciliary unit shows a bimodal distribution. It should be noted that counts due to intervals longer than the range of the analyser have been grouped into the last two channels

Striking changes in the distribution of intervals occur when patterned photic stimulus is presented to the eye This is demonstrated by the pretectal unit when the retina was stimulated by light, the intensity of which was modulated sinusoidally at 0 75 cycles/sec frequency There is a low, second mode in the distribution corresponding to a relative prevalence of long intervals corresponding to a silent period in the discharge during the cycle of light modulation

This is a fast, flexible and accurate method The analyses can be completed approximately 1,000 times more quickly than by conventional methods of photography and measurement of the enlargements As can be seen from the graphs, a sixty-four-fold range of intervals can be examined at any particular setting of the analyser channel-width, and the channel-width can be set to any desired value to accommodate the discharge pattern of the particular unit Large numbers of intervals can be examined (for example, 35,756 in the case of the retinal unit) for the total analyser count capacity is more than 8 million (2^{23}–64), and this is important in smoothing out the effects of statistical variation

A large field has been made accessible and is being opened up by this technique The information abstracted will ultimately form the foundation for the application of a communication theory to the visual system in particular and the nervous system in general

HÆMIN-PROTEIN BINDING IN PEROXIDASE AND METHÆMALBUMIN

By Dr A. C. MAEHLY*

Foundation for Medical Physics, University of Pennsylvania

WHEN protohæmin combines with the protein moieties of hæmoproteins its absorption maximum in the Soret region becomes intensified This has been ascribed either to the establishment of an iron-protein bond or to a bond involving the propionyl side-chains of the hæmin

O'Hagan and George succeeded in preparing artificial hæmoglobins[1] and myoglobins[2] with hæmins lacking carboxyl groups They concluded that in these hæmoproteins the essential binding must involve the central iron atom When coupling hæmin or hæm to human serum albumin, however, O'Hagan could demonstrate that the carboxyl groups of the hæmin molecule are involved in hæmin–protein binding[3] Little and Neilands[4] have recently investigated the coupling of hæmins to human serum albumin

Some simple experiments in this field were performed by me a few years ago Since this work was interrupted, the experiments are reported in abridged form Hæmin derivatives were prepared in which either the iron atom was missing (protoporphyrin) or the carboxyl groups were blocked (protohæmin-dimethyl ester) One or the other of these compounds was added to serum albumin or to apo-horseradish peroxidase, and the spectral changes in the Soret region recorded

Human serum albumin was kindly supplied by Dr M Surgenor (then in Boston) in the form of Cohn's fraction V Horseradish peroxidase was crystallized as described in ref 5 Protoporphyrin IX-dimethylester was made according to Grinstein[6] It melted at 221–225° uncorrected Free protoporphyrin IX was obtained by careful hydrolysis of the ester with 25 per cent hydrochloric acid as described in ref 7 and checking the absorption spectrum (peak at 412–413 mμ) Only freshly hydrolysed solutions were used Protohæmin IX-dimethylester was made as in ref 8 The crude product was purified on aragonite columns This crystal form of calcium carbonate proved to be superior to calcite or to mixtures of the two forms (Thanks are due to Prof F Daniels (Madison, Wisconsin) for generous gifts of samples of aragonite and calcite) The columns were prepared with dry benzene A benzene solution of the crude protohæmin IX-dimethylester was added and the column developed with benzene A green zone (*A*, about 5 per cent) travelled fastest, it was followed by a diffuse light-brown band (*B*, about 60 per cent) and a sharply defined dark brown zone (*C*, about 20 per cent) A brown area (*D*, about 12 per cent) stayed on top of the column Benzene eluted *A* (not identified) then *B* (pure protohæmin IX-dimethylester), and benzene/chloroform (1 1) eluted *C* (the monomethyl ester ?) *D* proved to be free protohæmin, elutable by chloroform/acetic acid (99 1)

Human serum albumin binds only protoporphyrin dissolved in acid aqueous solutions. If the solutions are neutralized or made alkaline, no appreciable spectral change takes place on addition of human serum albumin, possibly due to polymerization Fig 1 shows the Soret spectra obtained on adding 40 μl of a 128 μM protoporphyrin solution in N hydrochloric acid to 2 20 ml of 0·2 M Na_2HPO_4 on one hand, and to 2 20 ml of 3 0 μM human serum albumin in 0 2 M Na_2HPO_4 on the other hand The final molar ratio protoporphyrin/human serum albumin was thus 2 4 1 Rosenfeld and Surgenor[9] had found that human serum albumin forms complexes with ferri protoporphyrin in the ratios of 1 1 and 1 2 When solutions of protoporphyrin-dimethylester or of protohæmin IX-dimethylester in acetone were added to buffered human serum albumin and to buffer alone respectively, no spectral differences between the two resultant solutions were obtained

With horseradish peroxidase, similar, if somewhat less dramatic, results were obtained as with human serum albumin Neither protoporphyrin-dimethylester nor protohæmin IX-dimethylester, both in acetone solution, was bound to apo-horseradish peroxidase The spectra obtained on adding free protoporphyrin to apo-horseradish peroxidase are shown in Fig 2 40 μl of a 79 μM solution of protoporphyrin in 0 2 N hydrochloric acid were added to 2 20 ml. of 0 2 M phosphate buffer of *p*H 6 8, and to 2 20 ml of 1 3 μM apo-horseradish peroxidase in the same buffer respectively The concentration of active apo-horseradish peroxidase was determined by spectrophotometric titration of the protein with protohæmin of known titre The final concentration of protoporphyrin was thus 1 4 μM and the molar ratios protoporphyrin/apo-horseradish peroxidase = 1·1 · 1 0 When the protoporphyrin concentration was chosen at a lower level, spectra intermediate between those shown in Fig 2 were obtained, addition of larger amounts of protoporphyrin to both the blank and the 1 1 protoporphyrin–apo-horseradish peroxidase complex gave no further spectral change

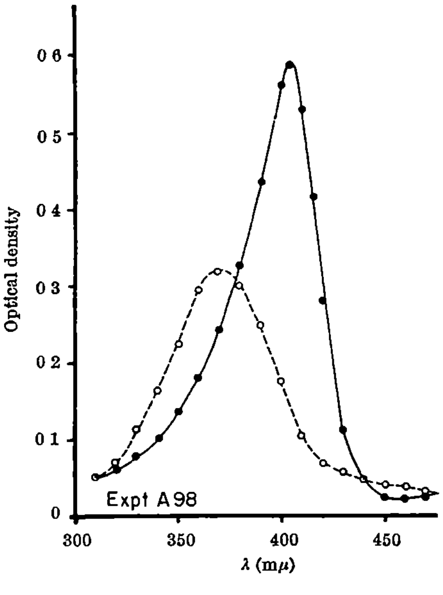

Fig 1 Soret spectra of protoporphyrin IX in phosphate (Na_2HPO_4), in the absence (○ – ○) and in the presence (● – ●) of human serum albumin

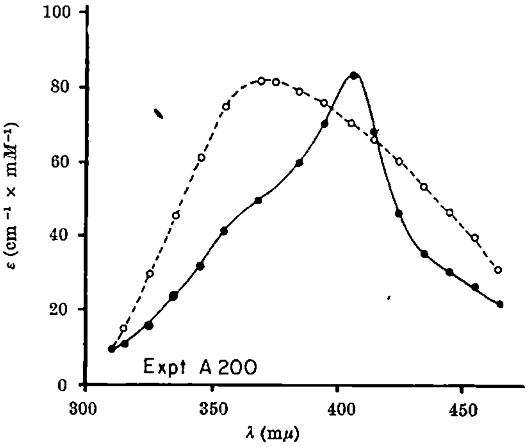

Fig 2 Soret spectra of protoporphyrin IX in phosphate buffer, in the absence (○ – ○) and in the presence (● – ●) of apo-horseradish peroxidase

The maxima of the Soret bands for horseradish peroxidase, protoporphyrin–apo-horseradish peroxidase, methæmalbumin and protoporphyrin–albumin all lie at 403 mμ, irrespective of the presence or the absence of the central iron atom Of more importance is the fact that the extinction coefficients of the porphyrin compounds are equal to or higher than those of the hæmin compounds This is shown in Table 1

Table 1 EXTINCTION COEFFICIENTS, $\varepsilon_{m\mu}$, OF HORSERADISH PEROXIDASE AND METHÆMALBUMIN AND THEIR IRON-FREE COUNTERPARTS AT THE PEAK OF THE SORET BAND AT 403 mμ

Horseradish peroxidase recombined from apo-horseradish peroxidase and protohæmin, *p*H 6 8	81 cm⁻¹m*M*⁻¹
Protoporphyrin–apo-horseradish peroxidase, *p*H 6 8	83 ,,
Methæmalbumin, *p*H 7–10 (cf ref 9)	81 ,,
Protoporphyrin human serum albumin, in Na_2HPO_4	116 ,,

A freshly prepared 1 3 μM solution of the protoporphyrin–apo-horseradish peroxidase complex did not react with methyl hydrogen peroxide as judged by the appearance of the Soret spectrum Protohæmin to a final concentration of 0 87 μM was now added to blank and solution no spectral change occurred Renewed addition of methyl hydrogen peroxide (2 μM) had no influence on the spectrum When protohæmin was added directly to free apo-horseradish peroxidase, complex II was rapidly formed with a Soret peak at 418 mμ The experiment shows that protoporphyrin competes with protohæmin for the same sites at the apo-horseradish peroxidase molecule The results emphasize the importance of the propionyl carboxyl groups of porphyrins in binding with proteins The intensification of the Soret band on binding seems to be mainly due to binding of the carboxyl group to the proteins investigated in the work described here

TRANSFERRIN DIFFERENCES IN CHIMPANZEE SERA

By Prof J BUETTNER-JANUSCH

Laboratory of Physical Anthropology, Yale University

TRANSFERRIN exists in a variety of molecular species in man and other mammals[1] Presumably the serum transferrins of the other Primates are similar to those of man While screening blood of Primates for differences in hæmoglobin, transferrin, α_2-globulin and cæruloplasmin, we have been able to test a number of chimpanzee sera and find results both similar to and different from those reported by Boyer and Young[2]

The samples came from four chimpanzees at the Department of Preventive Medicine at Yale ; 19 sera, given to us by Dr Edwin Isacson of Yale University, from animals at the Aero Space Medical Laboratory, Holloman Air Force Base, New Mexico , and 20 sera from the laboratory of Dr Morris Goodman, Wayne State University, Detroit, Michigan. The specific identification of the animals is not certain, though we believe them to be *Pan troglodytes* The variety of taxonomic labels given chimpanzees in the literature is not particularly informative Most of the animals were reported to have come from Senegal, Sierra Leone and the French Cameroons The 20 samples from Dr Goodman came from Orange Park, Florida

Sera were centrifuged at 16,000 r p.m at – 10° C , 1·5 ml of serum was treated for at least 1 hr with 0 5 ml. of ferrous citrate containing iron-59, 10 μc /ml The reaction was carried out either at ambient temperature (19° C.) or at 10° C Serum samples were inserted directly into precast slots in 12–15 per cent starch–gels made with 0 021 *M* borate buffer, *p*H 8·6 The electrophoresis was run in the vertical position at 6 V /cm for 16–18 hr After the run was completed, each gel was sliced in half One half was stained with amido-black dye in methanol/water/acetic acid solvent (5 5 1) The other half was wrapped in 'Saran Wrap' (Dow Chemical Corporation) and placed on a sheet of Kodak No-Screen X-ray film for 24 hr The films were developed in Kodak *D*-8 or *D*-11 developer The bands on the radiograph so produced were compared with various bands found on the section stained with amido-black The serum patterns were compared in repeated runs with the serum patterns of Yale College students and with those of a number of other Primates

A diagram of the transferrin types found is shown in Fig 1. We cannot label our patterns with the same designations that Boyer and Young[2] gave their transferrin phenotypes, since we could compare their patterns with ours only on the basis of the position of band *C* from a human homozygous *TfC* individual We have chosen to number our bands in order of decreasing mobility and name the types with inclusive numbers We found eight separate, distinct transferrin bands on the various radiographs, though never more than five in one individual serum. We name the band with the greatest mobility number 1, the one with lowest, 8 For example, the serum which had five bands, 3, 4, 5, 6 and 7, we named type 3–7 In Fig 1, human type *CC* is shown as well as one of the most frequent transferrins found in the African vervet or green monkey, *Cercopithecus aethiops* Band 3, which corresponds to no other Primates' transferrin that we know, was usually the densest band on the radiographs However, at least one of the eight bands showed up as a dense spot on the radiograph of at least one serum Therefore, we see no reason for distinguishing them on the basis of the extent to which they affect the X-ray film Table 1 shows the frequencies of the various types of transferrins

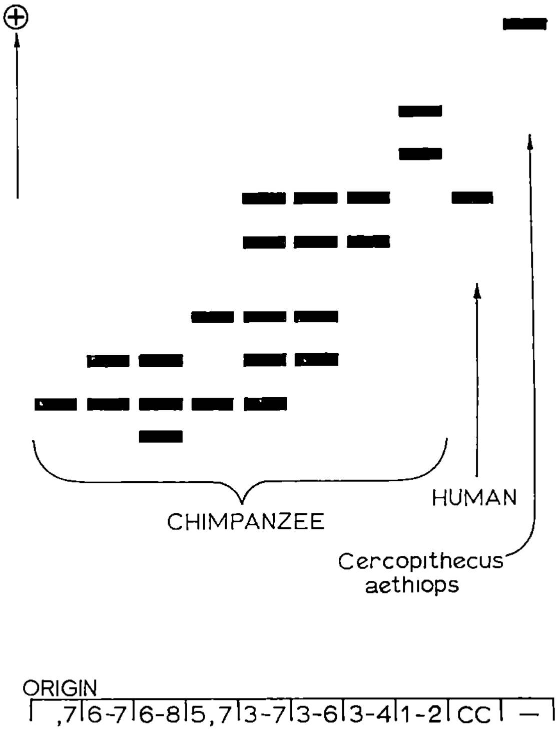

Fig 1. Diagram of electrophoretogram illustrating relative mobilities of transferrin bands in various chimpanzees compared with a human *TfC* homozygote and a common transferrin type from *Cercopithecus aethiops*

Table 1 Frequency of Transferrin Types in Chimpanzees

Type	Total	Number of animals* Group 1	Group 2	Group 3
1–2	1		1	
3–4	2		1	1
3–6 [*AC*]	2		2	
3–7 [*AD*]	7		7	
5, 7	2			2
6–7	14	1	2	11
6–8	12	2	4	6
,7	1		1	
	41†	3	18	20

* Group 1 are chimpanzees from Yale University, group 2 from Holloman Air Force Base, group 3 from Orange Park

† Two sera of the original 43 produced unreadable patterns on each of three runs

Exhaustive experiments in which each sample was saturated with iron-59 could not be undertaken because of the relatively small quantities of serum Nevertheless, where we had enough material and could add a large excess of iron-59, we found that bands which were faint on the original radiograph continued to be faint after addition of an excess of iron-59 The possibility occurs that the degree to which the transferrins are saturated *in vivo* before the blood samples were taken plays a part in the extent to which each band will take up iron-59 *in vitro* (Bearn, A , private communication)

It seems reasonable to identify our 3–7 type with the *AD* type of Boyer and Young, and our 3–6 type with their *AC* The other types do not correspond. The lack of correspondence may be due to species differences Our chimpanzees belong to a group labelled *Pan troglodytes* ; *Pan satyrus*, the name given the chimpanzees from which Boyer and Young received samples, is not known to us and is not recognized as a specific name by Fiedler[3], the name list at present in widest use It is possible that these are the dwarf varieties of the Congo chimpanzee described by Schwarz[4] Boyer (private communication) has stated recently that his animals were identified as *Pan troglodytes* by W. L Straus, jun

Another possibility is that these results are an additional demonstration of the marked polymorphism that chimpanzees show for the transferrin trait. Most of the animals showed the 6–8 and 6–7 patterns The other sera were distributed more or less randomly among the other types. In other words, there are no marked frequency differences between the Holloman chimpanzees and the Orange Park chimpanzees, despite apparent differences in place of origin in Africa

The serum patterns of these chimpanzees were compared with all the other Primates available to us One of our most striking findings is that only *Tupaia glis*, of all the Primates tested, showed iron-binding β-globulins which moved to the same general area on the gels as did those of the chimpanzee All other Primates available to us, except man (we have not been fortunate enough to obtain a sample from *Tarsius* yet), showed iron-binding bands of the β-globulins which have two and even three times the mobility of those of the chimpanzee

We found early in our work that it is best, as Boyer and Young showed, to use borate buffers in the gels and in the electrode trays in order to obtain the fine resolution of chimpanzee transferrin bands necessary to demonstrate multiple zones No other Primates, however, showed more than three iron-binding zones, though many other bands appear in the β-globulin region when macaque sera are subjected to electrophoresis in vertical starch-gels[5]

Unfortunately, it is not possible, at present, to discuss the possible modes of inheritance of this trait in the chimpanzee There are no good pedigrees available now, and it is unlikely that matings critical for working out the inheritance will occur

The multiplicity of the transferrin bands is similar to the situation in cattle β-globulins reported by Ashton[6] It is not clear yet whether all the bands in the β-globulin region of Primates represent separate alleles or whether the mode of inheritance is more complex The situation is made more complicated by the fact that the transferrin bands and the β-globulins do not show a one-to-one correspondence. A more detailed account of the β-globulins in Primates will be published later

I wish to thank Dr Edwin Isacson and Dr Francis Black of Yale University and Dr Morris Goodman of Wayne State University for their co-operation. The work on this project was performed under grant *RG*-6053 of the United States Public Health Service

MECHANISM OF STREPTOMYCIN ACTION ON BACTERIA: A UNITARY HYPOTHESIS

By Dr. CHARLES R. SPOTTS* and Prof. R. Y. STANIER
Department of Bacteriology, University of California, Berkeley

THE response of a bacterium to the presence of streptomycin in its environment is genetically determined, and can take three alternate forms, commonly known as sensitivity, resistance and dependence For a sensitive strain, streptomycin is toxic at very low concentrations , for a resistant strain, it is without effect on growth at considerably higher concentrations , and for a dependent strain, it is an essential growth factor Several different states are included under the broad heading of resistance, only one of which will be dealt with here We shall be concerned with the state in which a high level of resistance is acquired as a result of a single-step mutation from sensitivity, a type of resistance that is called indifference by some authors.

In *Escherichia coli*, genetic analysis has shown that sensitivity, dependence and single-step, high-level resistance are determined by multiple alleles of a single genetic locus[1–4] In terms of modern genetic theory, this fact implies that the three phenotypes are ultimately determined by alternate states of a specific protein, or of a regulatory system that con-

---

*Present address Laboratoire d'Enzymologie, Centre National de la Recherche Scientifique, Gif-sur-Yvette (Seine-et-Oise), France

trols the synthesis of a specific protein Hence all the epiphenomena that are specifically associated with each of these three phenotypes should fall into a causal chain, and the three causal chains should all lead back ultimately to three alternate functional states of the streptomycin locus This fundamental logical inference from the genetic data has been ignored in most theorizing about the mode of action of streptomycin Instead, there has been a regrettable tendency to embellish the account of each newly discovered effect of streptomycin on bacteria with yet another topical 'explanation' of the action of streptomycin

Most work on the physiological and biochemical effects of streptomycin on bacteria has been conducted with sensitive and resistant strains This preoccupation with sensitivity and resistance is mirrored by present explanatory hypotheses, which are directed primarily or exclusively towards interpreting the epiphenomena associated with these two states, and do not attempt to account for the epiphenomena associated with dependence One of us (C R S) has recently made a detailed physiological and biochemical study of streptomycin dependence in *Escherichia coli* The hypothesis which we shall present here is based primarily on the resultant findings, but it does have the somewhat novel advantage of explaining, in terms of structural modifications at a single intracellular site, some of the specific epiphenomena associated with sensitivity and resistance

Epiphenomena associated with Dependence on Streptomycin

Full experimental details of our work on streptomycin dependence will be published elsewhere[5] For the present purposes, it is sufficient to describe in summary fashion the rather complex epiphenomena which have been revealed by this work and by the work of earlier investigators

(1) A relatively high external concentration of streptomycin (greater than 100 μgm /ml) is necessary for growth of a dependent strain at maximal rate, when the streptomycin concentration falls below this *critical level,* the growth-rate becomes dependent on, and proportional to, streptomycin concentration[5-8] For any given strain, the absolute magnitude of the critical level varies in response to such factors as the salt content of the medium, the nature of the carbon source and the temperature At very low streptomycin-levels exponential growth can no longer be maintained, growth becomes arithmetic

(2) When the streptomycin-level of the medium is above the critical one, growing cells of a dependent strain have what we shall define as a normal macromolecular composition Under these conditions, the cellular content of protein, ribonucleic acid (RNA) and deoxyribonucleic acid (DNA) does not differ significantly from that of the corresponding sensitive strain, growing under identical environmental conditions in the absence of streptomycin[5]. However, when the streptomycin concentration of the medium is below the critical level, the macromolecular composition of the dependent cells becomes abnormal, and the degree of the abnormality is systematically related to streptomycin concentration[5] At progressively lower streptomycin-levels, the RNA content of the cells becomes greater, and the protein content becomes smaller DNA content is slightly sub-normal at low streptomycin-levels The effects of streptomycin concentration on cellular composition are shown in Fig 1

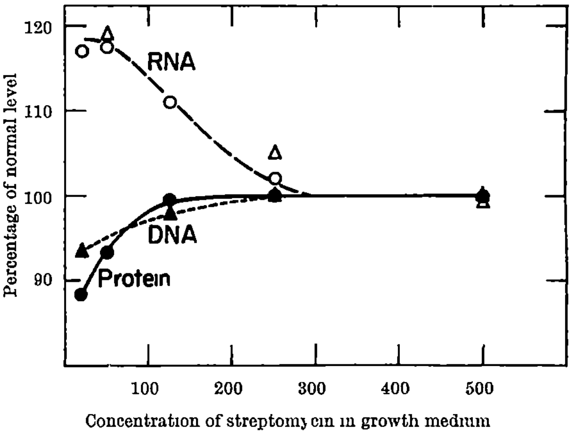

Fig 1 Effect of the streptomycin concentration of the medium on cellular composition of a dependent strain of *Escherichia coli*

(3) If dependent cells which have been grown with a supra-critical concentration of streptomycin are washed and re-suspended in a streptomycin-free medium, they continue to divide for a limited period, the number of divisions is a function of the concentration of streptomycin to which they were previously exposed[1,9] After the cessation of cell division, the cells can elongate[7,9,10], and further nuclear divisions can occur[11] A systematic analysis of this residual growth has revealed other significant facts[5] The cell mass increases exponentially at maximal rate for a short period, the duration of which is directly proportional to the streptomycin concentration of the medium from which the cells were taken The growth-rate then declines progressively over a period of 1–2 hr, after which growth becomes arithmetic Arithmetic growth, accompanied by an approximately six-fold increase of cell mass, continues for 16–20 hr before the stationary phase is finally attained The cessation of cell division coincides roughly with the termination of exponential growth; consequently the increase of cell mass during arithmetic growth is accompanied by a progressive elongation of the cells

(4) Deprivation of streptomycin is not immediately lethal: the size of the viable population, fixed by the cessation of cell division, does not begin to decline until several hours after attainment of the stationary phase[5].

(5) The initial period of residual growth is accompanied by a continuous and systematic change in the macromolecular composition of the cells[5]. In effect, such cells pass through the series of fixed compositional states which occurs in cultures that are grown at different sub-critical levels of streptomycin When the exponential phase of residual growth terminates, the cells have reached a state of extreme compositional imbalance (high RNA content, low protein and DNA contents) which is thereafter maintained throughout the course of arithmetic growth[5]

(6) If a supra-critical level of streptomycin is produced in a population in the course of arithmetical deprived growth, DNA synthesis rapidly regains its normal exponential rate The rate of protein synthesis also increases very shortly after streptomycin is added, but attains the normal exponential level a little more slowly The net synthesis of RNA ceases completely until the RNA-level of the cells has fallen by dilution to its normal value, after which RNA synthesis is resumed at the normal exponential rate[5]

Table 1 EFFECTS OF STREPTOMYCIN DEPRIVATION ON ENZYME SYNTHESIS BY A DEPENDENT STRAIN OF *Escherichia coli*

Functional class	Intracellular location	Enzyme	Specific activity, per cent of normal*
Respiratory	Soluble	Isocitric dehydrogenase	60
	Particulate	DPNH oxidase	60
	Particulate	Succinic dehydrogenase	40
	Gross respiratory activity (Q_{O_2})		45–55
Biosynthetic	Soluble	Threonine deaminase	100
	Soluble	5-Dehydroshikimic reductase	100
	Soluble	Glutamic dehydrogenase	50
	Soluble	Tryptophan synthetase	20
	Particulate	Dihydroorotic dehydrogenase	60
Non-functional under the conditions of cultivation used†	Soluble	Glucose-6-phosphate dehydrogenase	95
	Soluble	β-Galactosidase	5

*The specific activities (on a protein basis) of the enzymes examined remain constant throughout the arithmetic phase of deprived growth, and these values are taken to represent the deprivation-levels The 'normal' specific activity is that found in the cells during their immediately preceding exponential growth in a medium of the same composition, supplied with a supra-critical level of streptomycin

† The strain utilized for these experiments is constitutive for the production of β-galactosidase The medium contained glycerol as the sole source of carbon and energy

(7) Generally speaking, the intracellular state of the RNA in dependent cells growing with a critical level of streptomycin is 'normal', that is, it cannot be distinguished from that in sensitive cells of the same species growing under similar conditions without streptomycin The quantitative distributions of RNA between soluble and ribosomal fractions are closely similar, the sedimentation patterns of the ribosomes are identical, and the isolated ribosomes contain the same amounts of protein and RNA Streptomycin deprivation does not affect the intracellular state of RNA in dependent cells in any of the respects already mentioned Consequently, the increase in the total RNA content of the cells during deprivation simply reflects a very high differential rate of synthesis of *all* forms of cellular RNA[5]

(8) Since deprived cells have an abnormally high content of ribosomes, they also have an abnormally high content of ribosomal protein Hence the cellular content of non-ribosomal protein—broadly speaking, the total complement of enzymes—must fall very substantially as a result of deprivation Analyses of the enzymatic constitution of cells undergoing deprivation show that the decline in level is not uniformly shared by all the enzymes of the cell[5] The synthesis of some is virtually abolished, the synthesis of others is maintained at a rate which is in some cases normal and in some cases reduced, relative to the rate of total protein synthesis A summary of these data (Table 1) shows that the selective effects of deprivation on enzyme synthesis are essentially random No particular class of enzymes is specifically affected, nor is there a specific conservation of those enzymes essential for the maintenance of physiological function

(9) The streptomycin-dependent strain of *E coli* used in our experiments was lysogenic for phage λ, the formation of which can be induced by ultra-violet irradiation Even under conditions of severe streptomycin deprivation (that is, during the arithmetic phase of deprived growth) ultra-violet irradiation of the cells causes induction, with the subsequent lysis of the cells and liberation of active phage particles[5] Hence streptomycin deprivation does not prevent the synthesis by the dependent cell of functional DNA

(10) During the growth of a dependent strain, no change in the streptomycin content of the medium can be detected[5,12] A previous attempt to show streptomycin uptake by the cells[13] gave negative results However, by the use of radioactive streptomycin, we have been able to show that dependent cells bind a small amount[5] This bound streptomycin cannot be removed from the cells by repeated washings with phosphate buffer or with non-radioactive streptomycin The cells were grown in a medium that contained radioactive streptomycin at a concentration which was about double the critical level The amount of radioactivity in the cells was very close to the limits of detection, but with due regard for a large possible experimental error, we can say that under these conditions each cell binds irreversibly some 250,000 molecules of streptomycin Approximately half is extractable by hot water, the remainder is unextractable with cold perchloric acid, but can be completely extracted with hot perchloric acid

Interpretations of the Epiphenomena associated with Dependence

We assume that the dependent cell contains certain specific receptor sites, all of which must be combined with streptomycin for the maintenance of normal cellular function We further postulate that there is a relatively large number of such sites, all of which are identical in structure and in combining power for streptomycin When the medium has a critical streptomycin-level, the streptomycin concentration within the cells is just sufficient to keep all the receptor sites of the growing population combined with streptomycin At sub-critical levels, the internal streptomycin concentration is insufficient to keep all receptor sites combined, and cellular function becomes deranged At supra-critical levels, the streptomycin within the cells is more than sufficient to keep all receptor sites combined, and there is consequently an uncombined pool, the size of which is related to the external concentration This pool is probably loosely held by other cellular constituents, since it cannot exchange with external streptomycin, but can be extracted with hot water

We suggest that the intracellular receptor sites are the ribosomes, and that the firmly bound streptomycin in the cell (that is, the fraction unextractable by hot water) is all attached to ribosomes The number of molecules of streptomycin so bound by each cell is of the order of 100,000, so that there would be relatively few molecules (perhaps only one) bound to each ribosome Let us now see how these assumptions can be used to account for the distinctive epiphenomena which accompany streptomycin deprivation namely, the selective repression of the synthesis of some enzymes, and the over-production of all forms of cellular RNA

According to present concepts about the mechanism of protein synthesis, the ribosomes act as non-specific assembly sites for the manufacture of proteins[14-16] The specific protein which is synthesized at any given time on any given ribosome is determined by the transient attachment to the ribosome of a short-lived 'messenger RNA'[17-21]. The various messenger RNA's are direct gene products, each of which carries in its unique base sequence a copy of the genetic code. This base sequence is presumed to specify the amino-acid sequence of the protein molecule that is assembled on the ribosome.

We propose that mutation to dependence at the streptomycin locus causes a slight modification in the structure of all ribosomes. Although this modification is insufficient to change the gross properties of the ribosomes (as evidence by their normal sedimentation pattern and gross composition), it makes them unable to combine as effectively as ribosomes of the sensitive phenotype with certain messenger RNA's. The defect in combining power can be repaired by the attachment of streptomycin to the ribosome, an event which we shall call activation. The ribosomal structure characteristic of a dependent cell can have three possible effects on the synthesis of specific proteins.

(*A*) If a specific messenger RNA has no affinity for the ribosome of the dependent phenotype, ribosomal activation with streptomycin is indispensable for synthesis of the corresponding protein.

(*B*) If a specific messenger RNA has a reduced affinity for the ribosome of the dependent phenotype, activation with streptomycin is necessary for synthesis of the corresponding protein at maximal rate.

(*C*) If a specific messenger RNA has an unchanged affinity for the ribosome of the dependent phenotype, the rate of synthesis of the corresponding protein is not increased by activation with streptomycin.

After growth with a supra-critical concentration of streptomycin, dependent cells have a fully activated complement of ribosomes, and in addition contain an internal pool of streptomycin, proportional in size to the external concentration. In the absence of external streptomycin, such cells can continue normal growth as long as newly formed ribosomes can be fully activated at the expense of the internal pool. As soon as the pool is exhausted, the rates of synthesis of proteins belonging to categories *A* and *B* begin to fall. This event is translated into exponential growth at ever-diminishing rate, characteristic of the first period of deprivation. The concentration of activated ribosomes in the cells eventually falls to a point at which proteins belonging to category *A* practically cease to be formed, since the probability of the corresponding messenger RNA finding an activated ribosome during its short lifetime has become small. Provided that some of these proteins play an essential catalytic part, growth then becomes arithmetic, as actually observed in the second period of deprivation.

We must now see what interpretation can be offered for the increase in the rate of RNA synthesis which sets in as soon as the streptomycin-level begins to limit the growth-rate. Magasanik and Neidhardt[22,23] have made a detailed study of the control of RNA and protein synthesis during normal bacterial growth. Their findings suggest that growth-rate (which is essentially a reflexion of the rate of total protein synthesis) is determined by the concentration of RNA in the cell. This implies the existence of a feed-back control on RNA synthesis. When a cell is placed under conditions where biosynthetic precursors can be manufactured more rapidly than they can be used for protein synthesis, a larger fraction of the flow of carbon and nitrogen is directed into the synthesis of RNA and of ribosomal protein. This preferential synthesis continues until the limitation placed on the rate of protein synthesis has been overcome, and the cell has achieved metabolic balance under a new set of steady-state conditions.

The growth of dependent cells with sub-critical levels of streptomycin provides the first known instance of an *inverse* relationship between growth-rate and cellular RNA content. How is this apparent anomaly to be explained? As soon as the streptomycin concentration in a dependent cell falls to a level that is no longer sufficient to activate all ribosomes, the rate of protein synthesis begins to fall and biosynthetic precursors begin to accumulate. At this point, the feed-back control mechanism comes into play, and a larger flow of raw materials is directed into the formation of RNA and ribosomal protein. But in the dependent cell under the conditions of streptomycin deprivation, the production of more ribosomes only accentuates the imbalance which it would correct in a normal cell, since it decreases the rate of synthesis of all proteins belonging to categories *A* and *B*. The feed-back control mechanism goes out of regulation, and more and more ribosomes and soluble RNA are made by the cell. The ribosomes can, it is true, serve for the synthesis of proteins belonging to category *C*, but since the proteins of this category constitute an arbitrary array, in terms of their physiological function, the only consequence is to establish a condition of enzymatic imbalance. This affects not only biosynthetic systems, but also the systems responsible for energy-yielding metabolism, as shown by the fact that deprivation can result in a substantial depression of the Q_{O_2} of the cells[5,24].

The ribosomes made during deprivation are potentially fully functional, and the addition of streptomycin to the deprived culture causes their rapid activation. As a consequence, the rate of synthesis of the proteins belonging to categories *A* and *B* immediately rises relative to that of proteins belonging to category *C*. As the enzymatic imbalance in the cells is overcome, exponential growth can be resumed. With the rise in the rate of protein synthesis that follows the re-introduction of streptomycin, the feed-back control on RNA synthesis again comes into normal operation, with the consequence that further net synthesis of RNA is totally repressed until the ribosomal content of the cells has been reduced by growth to a level that once again limits protein synthesis.

The hypothesis which has been outlined here is admittedly complex, and constructed on indirect experimental evidence. Nevertheless, it provides a logically coherent formal explanation for *all* the distinctive epiphenomena associated with streptomycin dependence. It also leads to many explicit predictions, some of which should be susceptible of immediate experimental test.

As emphasized in the introduction, any hypothesis concerning the mode of streptomycin action on bacteria must be deemed inadequate unless it can explain in functional terms the allelism of sensitivity, resistance and dependence. In the remaining section of this essay, we shall accordingly show briefly how this hypothesis can be extended to interpret sensitivity and resistance.

Interpretation of Sensitivity and Resistance

We have postulated that in the dependent phenotype the ribosomes have undergone a slight structural modification which reduces their affinity to a greater or less extent for some messenger RNA's , and further, that a normal affinity can be restored by activation with streptomycin We are therefore led to assume that the sensitive and resistant phenotypes are, in the last analysis, expressions of other structural states of the ribosomes In both these phenotypes, it is obvious that the ribosomes have full affinity for all messenger RNA's in the absence of streptomycin Hence the postulated structural difference between them is of such a nature that its functional consequences are expressed only in the presence of streptomycin We propose that the ribosomes of sensitive cells have a structure that confers on them a very high affinity for streptomycin, and that the resultant combination with streptomycin wholly prevents the attachment of messenger RNA's, thus abolishing protein synthesis The ribosomes of resistant cells, on the other hand, have a structure such that they cannot combine with streptomycin ; hence streptomycin cannot impede the attachment of messenger RNA's, and the synthesis of proteins

The first obvious prediction which can be made on the basis of this suggestion is that sensitive and resistant cells should have markedly different binding capacities for streptomycin This is confirmed by the recent work of Hancock[25] Placed in the presence of a minimal inhibitory concentration of streptomycin, sensitive cells can bind a small quantity irreversibly. The quantity so bound is of the same order as that which we find to be bound by dependent cells placed in the presence of a far higher external streptomycin concentration Resistant cells, on the other hand, bind a relatively insignificant amount of streptomycin[25]. The much lower binding capacity of the resistant cell could, of course, be explained by the assumption that streptomycin cannot enter cells of this phenotype However, if a permeability change is invoked to explain resistance, its allelism with dependence and sensitivity should imply that these two phenotypes are also basically determined by special states of the permeability barrier (presumably the cell membrane) At least for dependence, such a premise is wholly devoid of explanatory value

Another prediction which follows from our hypothesis is that streptomycin should act as a very powerful inhibitor of protein synthesis in cells of the sensitive phenotype, but not in cells of the resistant phenotype This prediction is confirmed by the observations of Erdos and Ullman[26,27]. They have found that in extracts of cells of the sensitive phenotype, low concentrations of streptomycin abolish amino-acid transfer from soluble RNA to protein , this effect of streptomycin is not demonstrable in extracts of cells of the resistant phenotype The demonstration of this differential effect of streptomycin on protein synthesis in cell-free systems is of particular importance, since it reflects a major phenotypic difference between the sensitive and the resistant cell which cannot be attributed to a difference in permeability

One of us (C R S) thanks the National Institutes of Health, U S Public Health Service, for a predoctoral fellowship, during the tenure of which this work was carried out.

Note added in proof Dr D. T. Dubin and Prof B. D. Davis have recently observed that exposure of a sensitive strain of *E coli* to streptomycin results in the intracellular breakdown of the ribosomes (personal communication). This fact is fully consonant with our general hypothesis concerning the primary site of streptomycin action in bacteria, but implies that the special interpretation of sensitivity which we present must be amended streptomycin does not simply inactivate the ribosomes of the sensitive phenotype, it destroys them. Indeed, this amendment makes possible a much more satisfactory explanation of the various epiphenomena associated with sensitivity than does our original interpretation.

TEMPERATURE CHARACTERISTICS OF BACTERIAL VARIATION IN LEGUME SYMBIOSIS

By Dr. J. S. PATE

Department of Botany, Queen's University, Belfast

THERE is abundant evidence of wide variation within the legume nodule organism *Rhizobium* Cultural[1] and serological[2] characters have been used to define the free-living bacteria, while their behaviour in association with various legumes has been shown to range from non-invasibility[3] or infection but inability to nodulate[4] to all grades of harmony in symbiosis[5–7]

It is usual to describe bacterial variation in symbiosis by comparing the nodulating and nitrogen-fixing properties of various bacterial partnerships of one host genotype under identical growth condi-

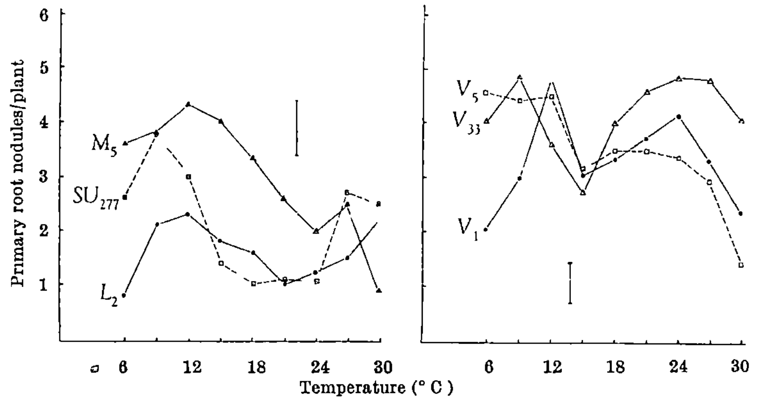

Fig 1 Effect of a range of constantly maintained temperatures on the nodulating performances of selected strains of nodule bacteria on barrel medick (*Medicago tribuloides* Desr) on the left, and purple vetch (*Vicia atropurpurea* Desr) on the right Code numbers refer to strains of *Rhizobium* Plants grown at 400 ft -candles light intensity, 99 per cent confidence limits are included

tions The purpose of this article is to report a new type of symbiotic variation where reaction to a range of environmental conditions is used to determine the physiological characteristics of host plant and invading bacterium

Purple vetch (*Vicia atropurpurea* Desf) and barrel medick (*Medicago tribuloides* Desr) were paired with selected strains of nodule bacteria of Australian or British origin Each host–bacterium combination was grown in culture rooms maintained at a series of constant temperatures (6–30° C) The nitrogen-free sand culture technique was used as described previously[8] Each growth series received 16 hr /day of fluorescent lighting giving intensities of 400, 600, or 800 ft -candles at sand-level in the culture vessels

In work on nodulation response to temperature, the collection of the plants was timed to coincide with the completion of nodulation of the seedling primary root Average nodule number in the 50-plant sample from the 5 replicate pots of a treatment was determined as a measure of initial response to infection Clearing roots in chloral hydrate facilitated the counting of the small nodules developed by some bacterial strains in unfavourable environments Fig 1 illustrates typical nodulation performances in vetch and medick All nodulation curves show optima at or near the extremes of growth temperatures, and comparisons of the relative magnitudes of these pairs of optima would indicate that certain bacteria (for example, V_{33} and L_2) are particularly effective in forming nodules at high temperatures Other bacterial strains (M_5 and V_5) illustrate the opposite effect Several investigations[8–10] have suggested that an existing nodule may exert inhibitory influences on its younger companions, and such a hypothesis might interpret the general depression of nodulation in the middle of the temperature-range as a direct consequence of a more active production of inhibitory substances by the first-formed nodules Similarly, a specific bacterial contribution to the production of inhibitory substances might account for the different temperature characteristics recorded in the nodulation of each partnership of a host plant

Results of a preliminary experiment on the interaction of light and temperature on the nitrogen fixation of bacterial associations of vetch and medick are shown in Fig 2 The values quoted refer to the first 5 weeks of nitrogen fixation, commencing when nodules first acquired visible hæmoglobin pigmentation In both species nitrogen fixation shows a well-defined maximum at 24° C , with symbiosis in barrel medick clearly more tolerant of high temperatures than in purple vetch (compare nodule formation, Fig 1) The higher light intensity benefits fixation particularly at low or medium temperatures The two barrel medick associations offer evidence of a bacterial factor influencing variations in symbiotic activity over the temperature-range Thus the L_2 strain shows significantly greater fixation at lower temperatures, while the reverse obtains at temperatures at or above 24° C These differences are reproduced in both light conditions and, like the initial infection responses, appear to represent minor variations on the general pattern of host-response to temperature

Table 1 records nitrogen analyses of dry weights for typical bacterial associations of vetch and medick harvested after 5 weeks of nitrogen fixation at 600 ft -candle light intensity

A specific inhibition of fixation processes by growth temperatures at or above 27° C is suggested in both associations from the low values for percentage nitrogen in dry weight By contrast, the depression of total fixation at or below 21° C (see Fig 2) is seen to be associated with the higher values for nitrogen percentage, suggesting that growth processes other than nitrogen fixation are retarded in conditions of lower temperatures

The two species studied here may be grouped with those described by Mes[11] (*Vicia sativa*, *Pisum sativum*,

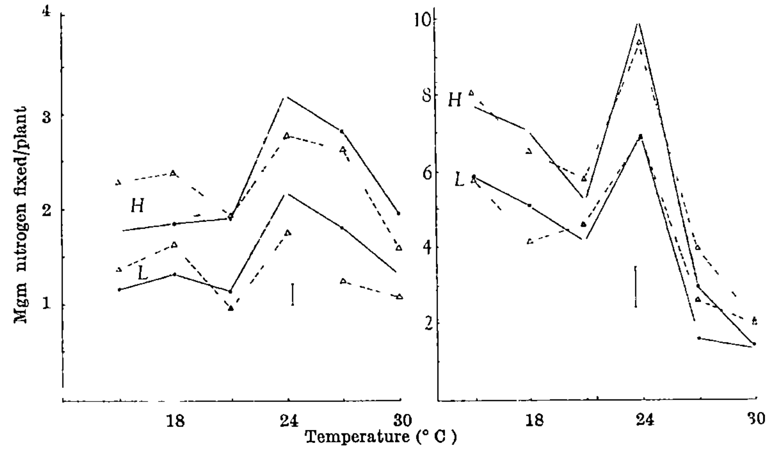

Fig 2 The effects of a range of constantly maintained temperatures and two light intensities on nitrogen fixation by bacterial associations of medick (left) and vetch (right) Code numbers refer to strains of *Rhizobium* 99 per cent confidence limits are derived from the 50-plant sample (5 replicate pots) of each treatment *H*, 800 ft -candles, *L*, 400 ft -candles light intensity, for medick, ●, BM_{101}, , L_2, Δ for vetch, ●, V_{33}, Δ, V_1

Growth temp (° C)		15	18	21	24	27	30
Nitrogen fixed as a % of plant dry weight*	Purple vetch—*Rhizobium* V_5	4 4	4 7	4 8	4 1	3 8	2 9
	Barrel medick—*Rhizobium* BM_{104}	3 9	4 3	4 4	3 9	3 7	3 0

* Corrected to exclude nitrogen furnished by cotyledons

Lupinus luteus) and Meyer and Anderson[12] (*Trifolium subterraneum*) as showing a specific suppression of symbiotic fixation at high growth temperatures Mes[11,13] has also described the opposite condition, where nitrogen fixation is specifically depressed by low temperatures (for example, in *Arachis hypogaea*, *Stizolobium deeringianum*, and *Glycine max*) The present work on *Medicago tribuloides* would suggest the possibility of selecting bacterial strains to combat such limitations of symbiosis in unfavourable growth conditions

Further experiments are being conducted to investigate symbiotic activity where host plants are subjected to a range of further environmental factors, including seasonal and diurnal thermo-periodicity and the presence of varied amounts of combined nitrogen in the rooting medium

CRYSTALLIZATION OF CYTOCHROME b_2 FREE OF THE DEOXYRIBONUCLEIC ACID COMPONENT

By PROF. R. K. MORTON and KATHRYN SHEPLEY

Department of Agricultural Chemistry, Waite Agricultural Research Institute, University of Adelaide

CRYSTALLINE cytochrome b_2 was isolated in 1954 by Appleby and Morton[1,2], who showed that it was identical with L(+)-lactate dehydrogenase of baker's yeast The crystalline enzyme is a flavohæmoprotein[1,3,4] It contains about 5 per cent of a deoxyribonucleic acid (DNA)[5,6] which appears to be homogeneous and which has a molecular weight of 10,000–12,000 as estimated by end-group analysis[7] The DNA-component may be dissociated from the flavohæmoprotein by dialysis against a 70 per cent saturated solution of ammonium sulphate[6,7] without any substantial change in the specific dehydrogenase activity of the enzyme[3,6] The flavohæmoprotein containing the DNA-component is now known as type I-cytochrome b_2, and that free of the DNA-component as type II-cytochrome b_2 (ref 8) As observed by Appleby and Morton[6], the DNA-free enzyme does not crystallize when dialysed for short periods under similar conditions to those used for crystallization of the DNA-containing enzyme

Unless otherwise specified, all procedures described in this article were carried out under essentially anaerobic conditions with oxygen-free solutions in a cold room at 0°–2° C (see ref 3)

To separate the DNA-component from type I-cytochrome b_2, a solution containing about 26 mgm /ml of three-times crystallized protein[3] was dialysed successively (for 15–24 hr in each case) against 50 per cent and 70 per cent saturated solutions of ammonium sulphate at *p*H 8 0 (refs 6 and 7) The precipitated protein was collected by centrifuging and washed with a 70 per cent saturated solution of ammonium sulphate at *p*H 8 0 The combined supernatants contained the protein-free deoxyribonucleic acid component The DNA-free flavohæmoprotein (type II-cytochrome b_2) was dissolved in a minimum amount of 0 5 *M* sodium lactate / 0 1 m*M* ethylenediamine tetraacetate / 0 04 *M* tetrasodium pyrophosphate, *p*H 6 8, centrifuged to remove a small amount of precipitate, and then dialysed against 0 05 *M* sodium lactate / 0 1 m*M* ethylenediamine tetraacetate / 1 m*M* magnesium sulphate at *p*H 6 8 There was no change in the dialysing solution for about 30 hr , at about which time turbidity appeared and increased gradually as dialysis was continued After several days, large pink crystals were observed adhering to the sides and bottom of the 'Visking' cellulose sac After 24 days, the crystals were collected and washed by allowing them to settle under gravity after suspending in 0 05 *M* sodium lactate / 0 1 m*M* ethylenediamine tetraacetate / 1 m*M* magnesium sulphate at *p*H 6 8 The size and density of the crystals created difficulties in collection and transfer ; centrifuging was unnecessary The shape of the larger crystals was recognizable without aid of a hand lens

Whereas the crystals of type I (DNA-containing)-cytochrome b_2 obtained under similar conditions belong to the tetragonal system, and are probably shallow bi-pyramids which appear as square plates when lying flat (see refs 1 and 3), the crystals of type II (DNA-free)-cytochrome b_2 belong to the hexagonal system and consist of hexagonal prisms with pyramids at both ends (Fig 1) Fig 2 shows measurements on average crystals of type I- and type II-cytochrome b_2 The largest crystals of type II-cytochrome b_2 were about three times the size of that illustrated in Fig 2, but they were somewhat fragile and difficulty was experienced in handling them without chipping the faces or the tips of the pyramids Crystals of type I-cytochrome b_2 are weakly and those of type II-cytochrome b_2 strongly anisotropic, especially when oriented in certain directions

A pellet of crystals of type II-cytochrome b_2 appeared darker in colour than a similar pellet of type I crystals, probably due to the difference in size and structure of the crystals Type II crystals

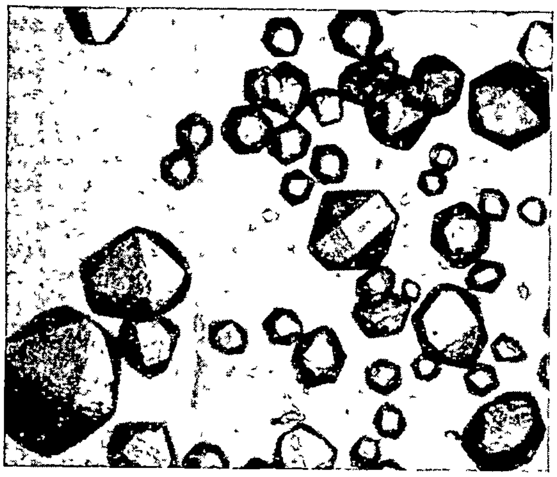

Fig 1 Crystals of type II (DNA-free)-cytochrome b_2 (× 125)

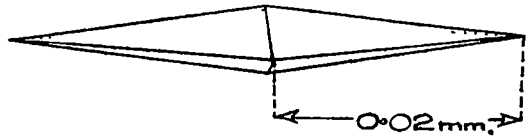
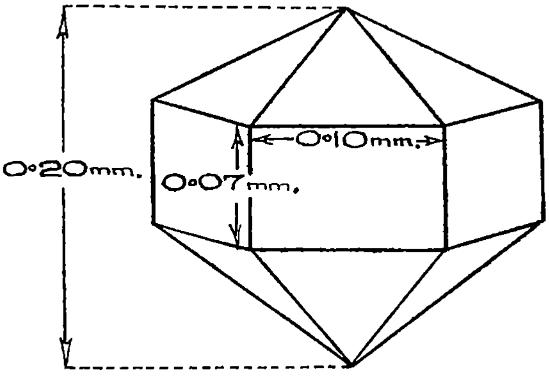


Type I



Type II

Fig. 2 Dimensions of representative crystals of type I (DNA-containing)- and of type II (DNA-free)-cytochrome b_2 obtained under similar conditions

dissolved slowly in 0 5 *M* sodium lactate / 0 04 *M* tetrasodium pyrophosphate / 0·1 m*M* ethylenediamine tetraacetate, *p*H 6 8. On dialysis of this solution (containing about 35 mgm protein/ml), under the conditions used for first crystallization, crystallization was complete in a few hours, the crystals had the same form as in Fig 1, but they were very much smaller All crystals, both in the initial and recrystallized material, appeared to be perfectly formed A number of preparations of crystalline type II-cytochrome b_2 have been produced as described

Table 1 shows comparative properties of solutions of crystalline type I- and type II-cytochrome b_2. The enzymic and physico-chemical properties are very similar, but the absence of the DNA-component from type II material causes a change in the position of the maximum absorption and in the corresponding extinction value in the ultra-violet region of the spectrum The absorption maximum at 269 5 mμ in type II-cytochrome b_2 appears to be due to the contribution of the riboflavin phosphate prosthetic group (which has an absorption maximum at 266 mμ) to the absorption due to the aromatic amino-acids, the flavin-free hæmoprotein derivative has a maximum at 278 mμ (refs 8 and 9)

The two different crystalline forms of type I- and of type II-cytochrome b_2 are distinctive features of the DNA-containing and of the DNA-free enzyme When a solution containing both types of cytochrome b_2 was dialysed as described for crystallization, both tetragonal plates (type I) and hexagonal prisms (type II) appeared in the precipitate The larger and denser type II crystals were separated from type I crystals by forming a layer of a suspension of mixed crystals (in 0 05 *M* sodium lactate/0 1 m*M* ethylenediamine tetraacetate, *p*H 6 8) over 0 5 *M* sucrose / 0 05 *M* sodium lactate / 0·1 m*M* ethylenediamine tetraacetate at *p*H 6 8 and centrifuging at about 100*g* for 5 min The type I crystals were almost completely retained in the uppermost layer, and type II crystals appeared in the precipitate Whereas the solution of mixed type I and type II material had absorption maxima at 265 and 269 mμ, the solutions of the separated crystals showed the distinctive maxima of type I (265 mμ) and of type II (269 5 mμ) material

The two crystal types may also be differentiated by fluorescence microscopy When stained with an appropriate concentration of aqueous acridine orange, type I crystals show a strong green fluorescence due to the presence of the DNA component. The fluorescence is distributed uniformly throughout the crystal. With an excess of dye, an orange-red fluorescence is obtained, as with deoxyribonucleoproteins of the cell nucleus However, type II crystals show no distinctive fluorescence on staining with acridine orange under the same conditions

Type I (DNA-containing)-cytochrome b_2 is regarded as the native, naturally occurring form of the

Table 1 COMPARATIVE PROPERTIES OF CRYSTALLINE TYPE I- AND TYPE II-CYTOCHROME b_2

Property	Type I	Type II
Specific enzymic activities*		
with heart-muscle cytochrome *c*	5,000	5,500
2 6-dichlorophenol indophenol	1,600	1,700
ferricyanide	6,200	6,100

POSSIBLE CAUSES FOR PRODUCTION OF ISOLEUCINE BY *STREPTOMYCES RIMOSUS*

By Dr. I. HORVÁTH, I. GADÓ and A. SZENTIRMAI

Research Institute for Pharmaceutical Industry, Budapest 7

It was observed that *Streptomyces rimosus* (strain *BS*21) when cultivated on media containing threonine[1] or α-keto-butyric acid[2] produces both isoleucine and acetylethylcarbinol According to refs 3–5, the biosynthesis of isoleucine and valine appears to proceed along the same pathway In spite of this fact no production of valine could be demonstrated in media containing serine or pyruvic acid Work described here was carried out in order to elucidate the possible causes of this phenomenon

Details concerning the methods and inocula used were published earlier[6,7] Also the media used in the present work were prepared similarly to those used earlier: 1 5 per cent glucose, 0 013 per cent KH_2PO_4, 0 3 per cent sodium chloride, 0 002 per cent 'Tween 80', and 0 5 per cent glycine or any other appropriate amino-acid in an amount corresponding to that of glycine by amino nitrogen content The *p*H before sterilization was 7 0. The media were prepared with tap-water In experiments with washed mycelia two-day-old cultures were used Washing was performed with distilled water The final dilution of mycelia in the incubation mixture was 3–5 mgm /ml dry mycelia

The demonstration of the enzyme synthesizing α-acetolactic acid was as follows 2-ml samples contained 5–10 mgm washed mycelia (dry weight), 0 1 m mole pyruvic acid, 0 02 m mole Na_3AsO_4, 0 3 m mole magnesium sulphate The 2-ml. samples were incubated at *p*H 7 0 for 2 hr at 28° C and the reaction was stopped by the addition of 0 2 ml 50 per cent (v/v) sulphuric acid After standing for 2 hr acetoin was steam-distilled from the mixture and determined as described in ref 8 When washed mycelium walls were used, arsenate was omitted and replaced by 0 02 m mole *p*H 7 0 phosphate buffer

In media where conditions favourable for production of isoleucine were present 0 7 mgm /ml of valine was found to have an inhibitory action on the production of isoleucine This inhibition appeared to be specific for valine as no other amino-acid (in similar concentrations of amino nitrogen) was found to have such an effect Isoleucine itself in concentrations of 0 8 mgm /ml also failed to inhibit production, while the usual amount of the same substance was produced in addition to the level added

When examining the production of isoleucine by washed mycelia, it was found that the rate and extent of production were very much influenced by the medium used for growing mycelia (Fig 1). Mycelia grown on a threonine-containing medium immediately started isoleucine production in the presence of threonine and glucose The production was not influenced by 100 μgm /ml final concentration of chloramphenicol When mycelia grown on a glycine-containing medium were used, the production of isoleucine started only during the fourth hour of incubation and could be completely inhibited by the addition of chloramphenicol (100 μgm /ml).

In incubation mixtures containing serine and glucose the mycelia grown on a threonine-containing medium were found to produce valine The production was remarkably enhanced by the addition of chloramphenicol (100 μgm /ml) (Fig 2) A similar production of valine could never be observed when mycelia grown on media containing any other amino-acid tested were used

Strain *BS*21 of *Streptomyces rimosus* contains a high level of constitutive serine- and threonine-deaminase (dehydrase) The next step of isoleucine synthesis from threonine is accomplished by the enzyme synthesizing α-acetolactic acid[9–16] We succeeded in

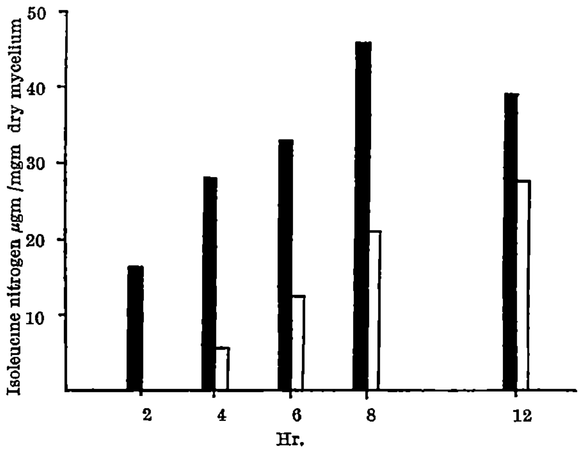

Fig 1 Isoleucine production by washed mycelia
The incubation mixture contained 1 per cent glucose, 0 5 per cent DL-threonine, 0 3 per cent sodium chloride, 0 6 per cent KH_2PO_4 (*p*H adjusted to 7 0 by the addition of sodium hydroxide) Mycelium (dry weight) 4 mgm./ml.

Blacks columns, mycelia grown on threonine-containing medium, white columns, mycelia grown on glycine-containing medium

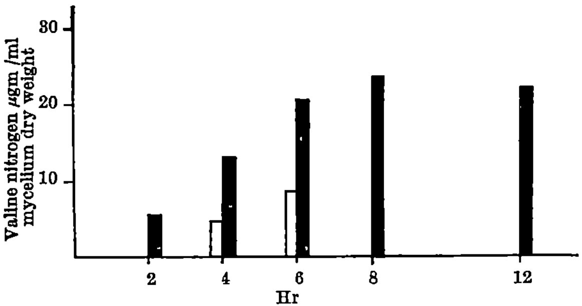

Fig 2 Valine production by washed mycelia
The incubation mixture contained 1 per cent glucose, 0 5 per cent DL-serine, 0 3 per cent sodium chloride, 0 6 per cent KH_2PO_4 (pH adjusted to 7 0 by the addition of sodium hydroxide) Mycelium (dry weight) 5 mgm /ml
White columns, no chloramphenicol, black columns, 100 μgm /ml chloramphenicol added

demonstrating this enzyme in the presence of arsenite or arsenate and we found that the activity of the enzyme exhibited a five-fold increase when the micro-organism was grown on media containing threonine or α-keto-butyric acid (Table 1) Depression of this enzyme by valine in *E coli* and *A aerogenes* has been observed[12,14] In our experiments such an effect of valine could be demonstrated similarly to the observations obtained with *Neurospora crassa*[16] The enzyme was found to be bound to the surface of mycelia and the activity of mycelium walls (washed with 0 3 m.mole of magnesium sulphate, pH 7 0) obtained by ultrasonic disintegration was the same as that of intact mycelia The former, however, was also active in the absence of arsenite or arsenate

Table 1 EFFECT OF THE MEDIUM ON THE ACETOLACTIC ACID SYNTHESIZING ENZYME CONTENT OF MYCELIA

Medium* (per cent)	μgm acetoin/mgm mycelium/hr
Glycine 0 5	3 6 (2 4– 4 8)
Glycine 0 5 + pyruvic acid 0 1	2 4 (1 8– 3 6)
DL-serine 0 7	3 0 (2 4– 4 2)
DL-threonine 0 79	13 2 (11 4–19 2)
DL-threonine 0 71 + DL-alanine 0 06	13 8 (10 2–20 4)
DL-threonine 0 71 + DL-valine 0 08	15 6 (12 0–22 2)
Glycine 0 5 + α-keto-butyric acid 0 1	10 8 (9 6–12 0)

* Basal medium 1 5 per cent glucose, 0 013 per cent KH_2PO_4 0 3 per cent sodium chloride, 0 002 per cent 'Tween 80'

The results obtained can be explained as follows · The α-keto-butyric acid produced from threonine or added to the medium enhances inductively the activity of acetolactic acid and aceto-oxybutyric acid synthesizing enzyme and probably also that of other enzymes involved in valine and isoleucine synthesis, thus resulting in an increased production of these two amino-acids Pyruvic acid did not seem to have a similar effect The cleavage of these two amino-acids with a branching carbon chain is inductively enhanced by valine, resulting in the inhibition of isoleucine production, while chloramphenicol enhances for the same reason the production of valine by mycelia grown on a threonine-containing medium The phenomenon observed, namely, the fact that an intermediary metabolite produced by one of the two amino-acids with similar pathways of biosynthesis or cleavage is able to enhance the biosynthesis or cleavage of both amino-acids is probably one of the general mechanisms controlling amino-acid metabolism

A SUBCELLULAR COMPONENT OF *CORYNEBACTERIUM DIPHTHERIAE* HAVING THE CAPACITY TO BIND ANTI-TOXIN

By PROF M YONEDA and M. MATSUDA

Research Institute for Microbial Diseases, Osaka University

ATTEMPTS to elucidate the intracellular events occurring during biosynthesis of toxin revealed that a subcellular component having the capacity to bind anti-toxin was formed in toxin-producing diphtheria cells, while no such binding was detectable with a similar component derived from the cells of non-toxinogenic, non-lysogenic strains *C*7 and *C*4 of *C diphtheriae* Examinations of the anti-toxin-binding capacity of various subcellular fractions by using a quantitative absorption test showed that the highest activity was always found in the sediment obtained by centrifugation at 14,500–100,000*g*, but there was no activity in the cell-wall preparation

In this work we used a substrain of toxinogenic Park Williams No 8, the toxinogenic strains *C*7(β) and *C*4(β) of *C diphtheriae* and the *C*7 and *C*4 indicator strains from which they had been derived by infection with β-phage[1,2]

These organisms were grown at 35° C with shaking in Pope's medium[3] under an optimal iron condition (0 08 μgm iron/ml) for production of toxin by the strains of Park Williams No 8, *C*7(β) and *C*4(β) After shaking for 20 hr , toxin content of the culture filtrates of these organisms was found to be 180, 18 and 12 Lf /ml , respectively, while no toxin was detectable in those of *C*7 and *C*4 When shaking was complete, the organisms were centrifuged out of the growth medium, washed in ribonucleoprotein buffer[4] three times, made up into thick suspension in the buffer and exposed to sonic oscillation at 10 kc /s

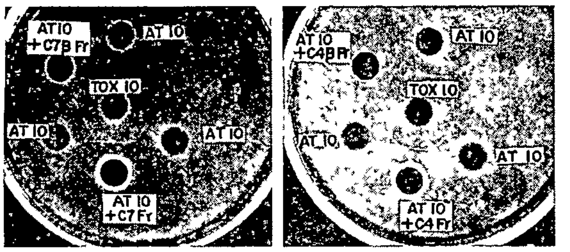

Fig 1 Agar-gel precipitation pattern demonstrating anti-toxin binding by fraction/14,500–100,000 of *C7(β)* and of *C4(β)* of *C diphtheriae*
TOX 10, 0 3 ml of 10 Lf /ml. of crystalline diphtheria toxin, AT 10, 0 3 ml of 10 units/ml of a horse standard anti-toxin, AT 10 + *C7βFr*, *C4βFr*, *C7Fr* or *C4Fr*, 0 3 ml of the supernatants of the mixtures of 0 6 ml of 10 units/ml anti-toxin and of 100 mgm (dry weight) of fraction/14,500–100,000 of each organism

for 30 min The whole disintegrates were then subjected to differential centrifugation as follows the supernatants obtained from the disintegrates by centrifugation at low speed (5,000*g* for 30 min) were centrifuged at 14,500*g* for 30 min and the supernatants thus obtained, which were still slightly turbid, were finally centrifuged at 100,000*g* for 60 min in a Spinco Model L The sediments precipitated at 14,500*g* and at 100,000*g* and washed three times in ribonucleoprotein buffer by centrifugation at the same gravity were referred to as fraction/5,000–14,500 and fraction/14,500–100,000, respectively Purified cell walls were provided by Prof S Kotani, of the Department of Bacteriology, Nara Medical College, these were prepared from toxin-producing cultures of Park Williams No 8 strain by the method described by Kitaura *et al* [5] in his laboratory.

Anti-toxin-binding capacity of these fractions and cell walls of Park Williams No 8 cells were determined, using a quantitative absorption test Thus, appropriate amounts of the materials corresponding to 70–400 mgm of the dry weight were suspended in 15 ml saline containing 15 units/ml of a standard horse diphtheria anti-toxin, incubated at 37° C for 15 min and the supernatants obtained by centrifugation were measured for the residual content of anti-toxin by flocculation with 15 Lf diphtheria toxin Anti-toxin-binding was also observed qualitatively with fraction/14,500–100,000 of each organism, using Ouchterlony's agar double-diffusion technique[6] In this experiment, the supernatants obtained by centrifugation from the mixtures of the fraction and anti-toxin which had been incubated at 37° C for 15 min , or the mixtures themselves were set against crystalline diphtheria toxin (3,300 Lf /mgm) prepared by the method of Katsura *et al* [7]

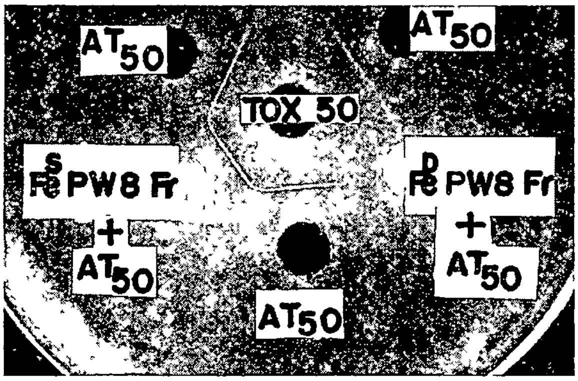

Fig 2 Agar-precipitation pattern demonstrating the absence of anti-toxin-binding capacity in the fraction/14,500–100,000 derived from Park Williams No 8 cells grown in the medium containing sufficient iron to suppress the toxin production
TOX 50, 0 3 ml of 50 Lf /ml of crystalline diphtheria toxin, AT_{50}, 0 3 ml of 50 units/ml of a horse standard anti-toxin, $Fe^{D}PW8Fr + AT_{50}$, 0 3 ml of the mixture of 0 6 ml of 50 units/ml anti-toxin and of 125 mgm (dry weight) of fraction/14,500–100,000 of cells of the cultures grown in an iron-deficiency for optimal toxin production
$Fe^{S}PW8Fr + AT_{50}$, 0 3 ml of the mixture of 0 6 ml of 50 units/ml anti-toxin and of 125 mgm (dry weight) of fraction/14,500–100,000 of cells of the cultures grown in the medium containing sufficient iron to suppress the toxin production

As can be seen from Fig 1, while a slight difference was observed in the appearance of precipitation of toxin with anti-toxin regardless of the presence of *C7* or *C4* fractions, no precipitation lines were formed between the toxin well and those for anti-toxin plus the *C7*(β) or *C4*(β) fractions, indicating an absence or a great decrease of anti-toxin in the supernatants of the latter mixtures

Table 1 shows the anti-toxin-binding capacity of various subcellular fractions obtained from Park Williams No 8 cells It may be seen that fraction/14,500–100,000 can bind as much as 0 68 unit of anti-toxin/mgm of the dry weight No activity was found in the purified cell wall preparation used Of particular interest was the observation that similar fractions from the cells of Park Williams No 8 strain which was grown in Pope's medium to which was added sufficient iron (8 μgm iron/ml) to suppress production of toxin showed no capacity to bind anti-toxin, as illustrated in Fig 2

Table 1 ANTI-TOXIN-BINDING CAPACITY OF VARIOUS CELLULAR FRACTIONS OF A PARK WILLIAMS NO 8 STRAIN OF *C diphtheriae*

Fractions	Anti-toxin absorbed (units/gm dry weight) Deficient iron*	 Sufficient iron†
Fraction/5,000–14,500	256	0
Fraction/14,500–100,000	681	0
Purified cell wall	0	—

* Fractions of Park Williams No 8 cells from the cultures grown in an iron-deficiency for optimal toxin production
† Fractions of Park Williams No 8 cells from the cultures grown in the medium containing sufficient iron to suppress toxin production

Preliminary work showed that 1 mgm (dry weight) of thoroughly washed fraction/14,500–100,000 of toxin-producing Park Williams No 8 has no lethal action in guinea pigs, but gives the intradermal reaction to rabbits which is equivalent to 20 m r d with a standard diphtheria toxin The reaction can be neutralized by anti-toxin Recent experiments have also shown that 0 8–5 0 units of anti-toxin can be formed in rabbits by immunizing with 5 mgm (dry weight) of the washed fraction in incomplete Freund's adjuvants Incidentally, fraction/14,500–100,000 can retain either the antigenicity or the original capacity to bind anti-toxin even after repeated washing (more than five times) in the ribonucleoprotein buffer or in other physiological buffers This clearly indicates that the active principle must be in a bound form Problems of relating subcellular structure to anti-toxin-binding capacity and the significance of the anti-toxin-binding principle in biosynthesis of diphtheria toxin still await further investigation

GEOCHEMISTRY

Uranium in the Sikhote-Alin Meteorite and its Relation to the Lead Method of Age Determination

The ages of lead of Earth and of meteorites are commonly based on the assumption that when these bodies were formed they contained lead of the same isotopic composition[1,2]. The present differences in the isotopic compositions of the lead in meteorites and also between common terrestrial lead and meteorite lead are due to radiogenic contributions from uranium and thorium since that time.

Recently, Starik *et al.*[3] measured the ratios of lead isotopes and the absolute amount of lead in a number of iron meteorites and found that the iron meteorites can be divided into two groups. One group has lead of 'primeval' isotopic composition, that is, the same as that measured by Patterson *et al.*[4] in the Canon Diablo meteorite. The other group has lead that is rich with isotopes lead-206, -207 and -208, relative to the isotope lead-204; this lead has an isotopic composition quite similar to that of common terrestrial lead (see Table 1). Reed *et al.*[5] have measured the uranium content of several iron meteorites and have found values in the range 10^{-10}–10^{-12} gm./gm. None of these meteorites, with the possible exception of Henbury, has lead enriched in the radiogenic isotopes. There is a dispute over the lead in Henbury[1,3].

Table 1. ISOTOPIC COMPOSITION OF LEAD IN THE SIKHOTE-ALIN AND CANON DIABLO METEORITES

Iron meteorite	Lead concentration	$^{206}Pb/^{204}Pb$	$^{207}Pb/^{204}Pb$	$^{208}Pb/^{204}Pb$
Sikhote-Alin	3×10^{-8}	17·89	15·84	38·19
	3×10^{-8}	17·55	15·60	37·97
Canon Diablo	—	9·46	10·34	29·44

In order to test the assumption that the excess of lead-206 is due to the radioactive decay of the isotope uranium-238, of lead-207 to that of uranium-235, and of lead-208 to that of thorium-232, we searched for uranium-235 in the Sikhote-Alin meteorite, which is a meteorite that clearly[3] has a lead-207 excess. We found less than $1{\cdot}4 \times 10^{-13}$ gm./gm. of uranium-235, corresponding to less than 2×10^{-11} gm./gm. of normal uranium. This amount is more than a factor of one hundred too small to account for the excess lead-207 in the Sikhote-Alin meteorite in 5×10^{9} years.

We irradiated two 7-gm. samples of Sikhote-Alin for 9 hr., and one uranium standard for 2 hr., in a pneumatic tube of the Massachusetts Institute of Technology reactor. The flux was 7×10^{12} neutrons/cm.^{2} sec. We measured the fission product, xenon-135, which has a 9·2 hr. half-life. Since the xenon-135 follows iodine-135, which has a 6·7 hr. half-life in the fission chain, we waited about 12 hr. after the irradiation before processing the samples for xenon. The fission product xenon-133 has been used to measure uranium in stone meteorites[6]. In order to remove possible uranium contamination, we dissolved away 10 per cent of the irradiated samples in nitric acid. We placed the remainder in an alumina crucible in our gas extraction system and melted it by induction heating. The sample was kept molten for 1 hr. in the presence of carrier gas. The carrier used with the first sample and with the uranium standard was xenon, the carrier used with the second sample was a 50–50 mixture of xenon and argon. At the end of the heating, only several small droplets remained in the crucible, the rest of the material had evaporated to the walls of the crucible and the furnace. The hydrogen was pumped away from the gas by its diffusion through a hot palladium thimble. The remaining gas was kept over hot calcium (550° C.). The xenon yield from the first sample and from the uranium standard was 100 per cent. This xenon was taken from the calcium and put into a Geiger counter. For the second sample the gas was removed from the calcium by adsorption on charcoal at the temperature of liquid nitrogen. Argon was removed from the charcoal at 0° C. and xenon removed at 160° C. The xenon yield was 65 per cent; this xenon was added to a Geiger counter. The Geiger counter was removed from the extraction line and placed in an iron shield; the background rate was 15–20 counts/min. The uranium standard consisted of $3{\cdot}0 \times 10^{-8}$ gm. of normal uranium ($2{\cdot}1 \times 10^{-10}$ gm. of uranium-235) in the form of uranyl nitrate evaporated from solution on an aluminium foil. This sample was placed with 7 gm. of iron in an alumina crucible and subjected to the identical experimental procedure that was used with the first Sikhote-Alin sample. The xenon from the standard when first counted 6 hr. after the melting gave 315 ± 5 counts/min.; this activity, which we followed for several days, clearly decayed with a 9·2 half-life to 35 ± 5 counts/min. The amount of long-lived activity agrees with the amount of xenon-133 expected. These results correspond to 420 ± 20 counts/min. of xenon-135 at the time of melting. The gas from the first Sikhote-Alin sample gave 70 counts/min. of a long-lived activity; there was less than 15 counts/min. of 9-hr. activity at the time of melting. This negative result corresponds to less than $2{\cdot}8 \times 10^{-13}$ gm./gm. of uranium-235 or 4×10^{-11} gm./gm. of normal uranium. The long-lived activity was probably argon-37, since this amount of argon-37 could result from 3×10^{-8} c.c./gm. of argon-36 or 5×10^{-7} gm./gm. of calcium in the sample. In the xenon fraction from the second sample the activity was within 5 counts per minute of background. This negative xenon-135 result corresponds to less than $1{\cdot}4 \times 10^{-13}$ gm./gm. of uranium-235 or 2×10^{-11} gm./gm. of normal uranium.

The lead-207 excess in the Sikhote-Alin meteorite is $2{\cdot}2 \times 10^{-9}$ gm./gm. A period of 10^{10} years is required for this lead-207 excess to result from $1{\cdot}5 \times 10^{-13}$ gm./gm. of uranium-235. There is less than $1{\cdot}4 \times 10^{-13}$ gm./gm. of uranium-235 according to our measurements. Such a large age seems unreasonable since it would require that the uranium produced in nucleosynthesis were practically pure uranium-235. The uranium and lead contents of the Sikhote-Alin meteorite are inconsistent with the common assumption made in determining lead ages for Earth and for meteorites.

Starik *et al.* have postulated separate origins, each with a different 'primeval' isotopic lead composition, for the two groups of iron meteorites. This postulate is consistent with the uranium results but makes ambiguous the interpretation of lead ages of meteorites and of Earth

One of us (D E F) is grateful to the U S Atomic Energy Commission for financial support, and to the Smithsonian Astrophysical Observatory for hospitality during the period in which this work was undertaken

GEOPHYSICS

Palæomagnetism of Hawaiian Lava Flows

PALÆOMAGNETIC investigations of volcanic rocks extruded in various parts of the world during the past several million years have generally revealed a younger sequence of lava flows magnetized nearly parallel to the field of a theoretical geocentric axial dipole, underlain by a sequence of older flows with exactly the opposite direction of remanent magnetization A 180-degree reversal of the geomagnetic field, occurring near the middle of the Pleistocene epoch, has been inferred by many workers from such results[1-3] This is a preliminary report of an investigation of 755 oriented samples collected from 152 lava flows on the island of Hawaii, selected to represent as many stratigraphic horizons as possible (Sampling details are indicated in Table 1) This work was undertaken because Hawaii's numerous thick sequences of lava flows, previously mapped as Pliocene to Historic by Stearns and Macdonald[4], and afterwards assigned ages ranging from later Tertiary to Recent, by Macdonald and Davis[5], appeared to offer an ideal opportunity to examine the most recent reversal of Earth's field

Remanent magnetization measurements using a spinner type magnetometer have now been completed on at least one sample from each of the 152 lava flows sampled, flow averages of all measurements completed to date before demagnetization are shown in Figs 1, 2 and 3 Demagnetization experiments of representative samples in alternating fields up to 800 œrsteds (peak) typically reduce the intensity of magnetization by 90 per cent but do not significantly change directions of magnetization Statistical analyses of the direction of magnetization in the samples, before and after demagnetization, and mineralogical studies are in progress

The preliminary measurements may be summarized as follows (1) The historic flows have directions of magnetization closely grouped about the present geomagnetic field direction on Hawaii, which has changed less than 2 degrees since about 1900 (2) None of the 152 flows sampled has reversed magnetic polarity (3) The scatter in directions of magnetization from flow to flow in a given sequence is much smaller than generally reported in comparable studies elsewhere (4) The average magnetization directions of most of the thick sequences sampled appear to differ significantly both from the present geomagnetic field and from the theoretical field of an axial dipole, moreover, the average directions in different sequences are different from each other

If the geomagnetic field reversal theory is true, then all the flows sampled on Hawaii are post-reversal and hence younger than early Pleistocene Alternative explanations (*a*) that lavas were not extruded when the field was reversed or were afterwards eroded or buried, or (*b*) that self-reversal occurred only in lava flows extruded while Earth's field was reversed, are much less plausible. Moreover, the stratigraphic distribution of the 152 lava flows sampled renders unlikely the possibility that a reversely magnetized sequence is present but was inadvertently missed

The closely parallel directions of magnetization found throughout these rather thick sequences of flows may be interpreted in two ways (1) An entire sequence may have been extruded in a time-interval too short for large amounts of secular variation to have occurred However, rates of secular variation as determined from direct measurements at observatories commonly cause more angular variation in several hundred years than is typically observed in the Hawaiian sequences Accumulation within several hundred years of sequences of more than 50 clearly distinguishable lava flows with total thicknesses up to 450 ft appears rather unlikely (2) That low rates of secular variation prevailed in Hawaii during the time these lava flows were extruded is a more plausible explanation The results from the Historic flows support this interpretation, and the direct measurements back to about 1900 also show less secular variation than is typical elsewhere in the world.

Table 1. SAMPLING DETAILS OF VOLCANIC SERIES EXAMINED

Geological Unit	Age	Flows sampled	Stratigraphic thickness (ft)	Description
Historic flows	Historic	9	—	Extruded at known historical dates between 1750 and 1955, members of Kau, Hualalai, and Puna Volcanic Series are included (Fig 1*a*)
Puna Volcanic Series	Late Pleistocene (?) and Recent	18	373 (I) 64 (II)	From Uwekahuna Bluff on west wall of Kilauea caldera Group II constitutes the lowest 64 ft of the section, and is separated from Group I by an erosional unconformity (Fig 1*b*)
Kahuku Volcanic Series	Pleistocene	29	99 (I) 188 (II) 54 (III)	Stratigraphically, flow Groups I, II and III are progressively lower (Fig 2*a*)
Hamakua Volcanic Series	Late Tertiary and Quaternary	27	135	From south-east side of Laupahoehoe Canyon These flows comprise the lower members of the Hamakua Volcanic Series, as described by Stearns and Macdonald (ref 4) (Fig 2*b*)
Pololu Volcanic Series	Pliocene (?)	50	453	From Waipio Valley These flows are from the lower member of the series, the highly weathered upper member was not sampled (Fig 3*a*)
Ninole Volcanic Series	Pliocene (?)	25	116+	From Kaiholena Ridge The upper 76 ft were sampled on the east side of the ridge, the lower 40 ft on the west, an unknown thickness between these is not exposed (Fig 3*b*)

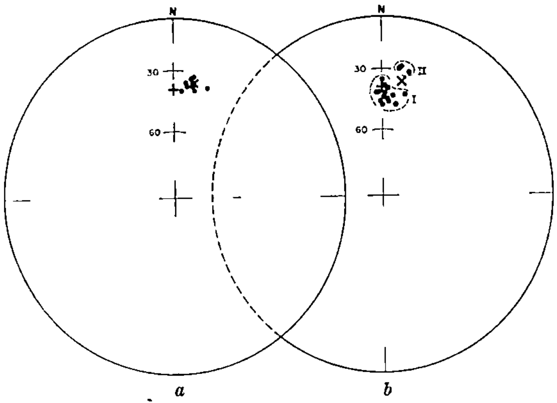

Fig 1 Directions of magnetization of (*a*) Historic lava flows and (*b*) Puna Volcanic Series ●, North-seeking polarity downwards, ○, north-seeking polarity upwards, +, direction of axially symmetric dipole field in Hawaii, ×, present geomagnetic field direction in Hawaii (Lambert equal-area projection with prime circle horizontal)

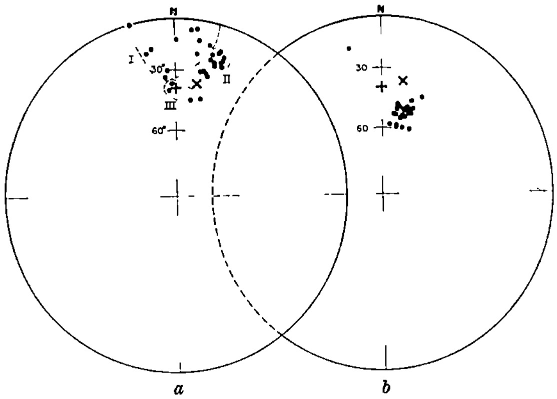

Fig 2 Directions of magnetization of (*a*) Kahuku Volcanic Series and (*b*) Hamakua Volcanic Series Symbols as for Fig 1

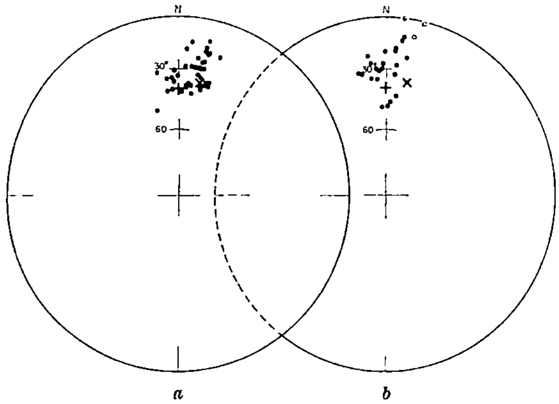

Fig 3 Directions of magnetization of (*a*) Pololu Volcanic Series and (*b*) Nınole Volcanic Series Symbols as for Fig 1

The differences observed between average magnetization directions of the different sequences of flows and the axial dipole field direction do not, in our opinion, indicate that Hawaii has undergone displacements and rotations in the Pleistocene Such an interpretation would require (*a*) lower latitudes than at present for Hawaii during the extrusion of the Pololu and Ninole Volcanic Series, (*b*) markedly higher latitudes during the extrusion of the Hamakua Series; (*c*) lower latitudes during Kahuku Series volcanism, (*d*) the present latitude during extrusion of the Puna Series, substantial rotations of the island of Hawaii since the early Pleistocene would also be required Much more plausible is the explanation that each of these sequences spans a time-interval too short to give an average direction of magnetization parallel to an axial dipole field Although absolute lengths of time cannot be given, it appears from this investigation that stratigraphic sections 450 ft thick and composed of more than 50 flows may accumulate on shield volcanoes in periods of time so short that the non-axial dipole field components do not vectorially add to zero Conversely, the geomagnetic field may have non-axial dipole components for times long enough for the accumulation of these relatively thick sections

PHYSICS

Emission of Ultra-Violet and Visible Radiation from Metals by the Impact of High-Energy Hydrogen Ions

IN a recent communication[1] we reported that ultra-violet and visible radiation is emitted from nickel by the impact of high-energy protons and positive ions, and that the visible part of the spectrum is continuous With a resolved proton beam we observed a flat peak between 4600 and 4900 Å in the distribution curve of spectral intensity

Apart from the radiation resulting from neutralization of positive ions on metal surfaces[2], the point of most significance is to investigate if the radiation observed by us contains spectral lines or the spectrum of the target element on which high-energy positive ions impinge If these lines (or spectrum) are present, their origin remains to be traced

Townes[3] has developed a theory of sputtering of metals under positive ion bombardment based on the assumption of local heating Kapitza[4] has explained in a similar way the emission of electrons from metal surfaces by positive ions This theory is supported by the experimental work of Oliphant and others[5], but some theories[6] of sputtering fail to account for recent experimental results The mechanism of sputtering of metals by positive ions is indeed not yet well understood

We wish to consider the probable mechanism of the emission of radiation from the target metal There seem to be two possibilities for the emission of visible and ultra-violet spectra of the target element (1) the radiation may be emitted from sputtered atoms excited in gaseous phase by positive ions, or by the secondary electrons knocked out of the target, (2) the excited atoms giving out this radiation may originate in the metal itself by the impact

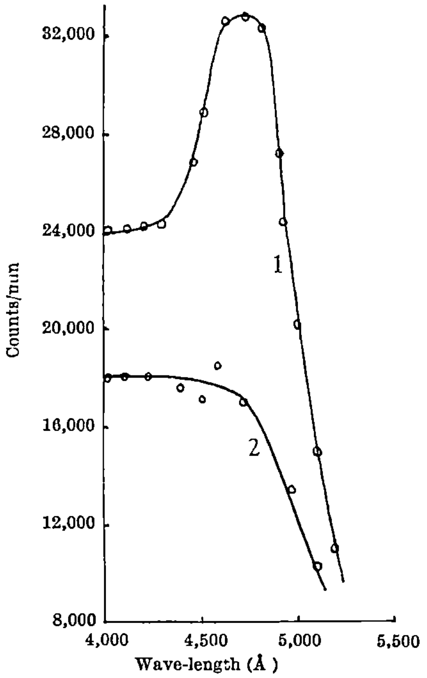

Fig 1 Spectral intensity of distribution curve for radiation emitted from nickel by high-energy positive ions of hydrogen Energy of positive ions = 200 keV , positive ion current = 4 μamp Curve 1, target cooled to low temperature, curve 2, target not cooled

of high-energy positive ions It is difficult to distinguish which of these two processes predominates in the emission of this radiation

If the metal target is cooled to a very low temperature where its thermal conductivity is comparatively high, the local heating effect will be reduced and consequently the sputtering will be less If the radiation observed were due to sputtered atoms excited in the gaseous phase, its intensity would be smaller at lower temperatures of the target Our experimental results, however, show that the reverse is the case.

The target is placed in a special chamber made throughout of glass It houses, besides the target, a copper reservoir filled with liquid air, so that impurities and volatile vapours in the chamber may condense on it The nickel target is degassed with electron bombardment to a bright red heat under a high vacuum for a sufficiently long time to make it clean and free from gas It is then cooled and kept permanently in thermal contact with a metal reservoir maintained at liquid-air temperature during experiments, and radiation emitted from it under the impact of hydrogen ions of energy 200 keV and current strength 4 μamp. is studied with Kodak gelatine filters Filter *2B* is used to cut out the ultra-violet region The distribution curve of spectral intensity shows a pronounced peak between wave-lengths 4600 and 4800 Å , which is a region of strong lines in the arc spectrum of nickel Curves 1 and 2 of Fig 1 show the distribution of spectral intensity obtained with the target cooled to low temperature and without cooling it respectively The visible spectrum is, so far as could be judged from analysis with gelatine filters, continuous within the range studied The intensity of the ultra-violet radiation between 4000 and 3300 Å is greater than that of the visible region as in previous experiments

The presence of the peak in the region of prominent nickel lines in curve 1 leads us to think that this radiation is emitted from the excited atoms which originate in the metal itself under the impact of high-energy positive ions The continuous nature of the spectrum, on the other hand, suggests that some sort of electron plasma oscillations may occur in the metal due to positive ion bombardment on it, and may give rise to this radiation

We believe that, with our experimental arrangement, the chances of accumulation of impurities on the cooled target are small, and consequently the increase in the intensity of the radiation emitted from the cold metal surface cannot be attributed wholly to the excitation of atoms of any dirty film on it.

Details of the chamber and the target cooling arrangement are being described elsewhere

We are grateful to Sir George Thomson for suggestions and advice, and to Sir Mark Oliphant for his interest throughout this work

High-Speed Direct-Recording System for Electron Diffraction

AN electron diffraction system for the quantitative investigation of rapid phase changes in solids has recently been completed The system will record an electron diffraction pattern of the Debye–Scherrer ring type in 50 msec , giving the electron intensity at the peaks of strong reflexions to an accuracy of 2 per cent The system gives an improvement in speed of direct recording of about four orders of magnitude[1], and is thus attractive for investigating quantitatively rapid changes in solids such as polymorphic transformations, transitions from the amorphous to the crystalline state, diffusion in alloys. It is also suitable for investigating controversial questions in electron diffraction such as the transition from geometrical to dynamic diffraction conditions[2,3]

Fig 1*a* shows a typical record from a polycrystalline gold film about 300 Å. thick. There are in fact two superimposed traces each of 100-msec. duration showing profiles of rings from 220 to beyond 531 The display also shows the profile of the primary beam after it has traversed the film, this gives a continuous measure of the angular resolution of the electron optical system. Once the information in the diffracted beams has been obtained at a sufficient resolution and level it is, of course, easy to magnify the diffracted profiles on the display Thus Fig 1*b* shows the inner rings of the gold together with the main beam in greater detail

Figs 2*a* and *b* show a high-speed amorphous-to-crystalline change in a film of silver in response to sudden heating Fig 2*a* is the envelope of fifty traces, the first of which shows almost no rings while

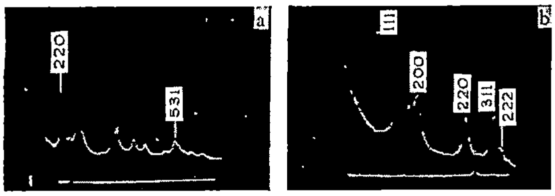

Fig 1

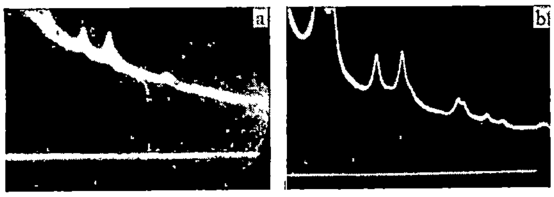

Fig 2

the last trace, 5 sec later, shows the rings considerably developed After 200 sec (Fig. 2*b*) there is little further change

The ultimate speed of recording in such a system is set by shot noise in the diffracted beams. The limitations are the same as those of the scanning electron microscope[4] Measurements show that the intensities at diffracted peaks are about 10^{-9} amp. Thus, for an accuracy of 1 per cent at such a peak, a picture point may be recorded in about 2 μsec One may expect that recording times for complete diffraction patterns of 1 msec are a question merely of improvements in technology.

Isotopic Composition of Atmospheric Hydrogen and Methane

In a recent communication, Bishop and Taylor[1] express the opinion that the tritium concentration of free hydrogen in the atmosphere has been rising over the past ten years, with a doubling time of approximately 18 months The authors suspect that artificial tritium was released into the atmosphere several years before the Castle test series in 1954, which is commonly assumed to have led to the first pronounced rise in the tritium concentration of terrestrial surface water Bishop and Taylor's communication includes a diagram of the logarithms of all the experimentally determined tritium values in free atmospheric hydrogen plotted against time The plot shows that the values follow a straight line that includes the first value obtained by Faltings and Harteck[2] on atmospheric hydrogen collected in 1948

The question of an addition of artificial tritium into the atmosphere prior to 1954 is of considerable importance in connexion with estimating the natural rate of production by cosmic rays of tritium, which is in general assumed to be of the order of 1 tritium atom per sec per cm ^{2} of Earth's surface

We have been able to secure a sample of atmospheric hydrogen, dating from 1948, contained in 'raw neon' in a regular cylinder, through the courtesy of Mr F R Balcar of the Air Reduction Co, New York This gas gave the following values

T/H = $3\,5 \pm 0\,1 \times 10^{-14} \equiv 35{,}000$ tritium units
δD = $-5\,4 \pm 0\,2$ per cent relative to Lake Michigan water standard

This tritium concentration is very close to that found by Begemann in hydrogen collected shortly before the Castle tests in 1954, and to the value for 1954 represented by the straight line through the points measured by several investigators afterwards It therefore appears unlikely that artificial tritium has influenced significantly the tritium content of atmospheric hydrogen prior to 1954. The deuterium value shows, in agreement with previous findings[3-4], that equilibrium between atmospheric water vapour and hydrogen is not established at ordinary temperatures

A most remarkable observation was recently made by Bishop *et al* [5] The tritium content of atmospheric methane is also very high and only about a factor of 5 below that of present-day atmospheric hydrogen The authors state that they are unable to suggest any satisfactory explanation for the source of this tritiated methane. They suspect an artificial origin

We have independently investigated one sample of atmospheric methane, which was collected in January 1960, by the Linde Co in Gary, Indiana. This sample was large enough to enable us to carry out very accurate, routine carbon-14 and tritium analyses in the La Jolla Radio-carbon and Tritium Laboratories. We are not able to propose any satisfactory explanation for the following experimental findings, but hope that our results, which include deuterium and carbon-13 values, may help in the future in interpreting the observed facts Measurement of carbon-13 was carried out in the laboratory of H Craig (University of California, San Diego), who wishes to discuss his result more extensively in a separate paper A second tritium determination by F Begemann at Mainz gave exactly the same result as ours

T/H = $1\,94 \pm 0\,1 \times 10^{-14} \equiv 19{,}400$ tritium units
^{14}C = $75\,2 \pm 0\,5$ per cent of standard wood, or 60 per cent of atmospheric carbon dioxide in 1960
δD = $-4\,2 \pm 0\,2$ per cent relative to Lake Michigan standard water
$\delta^{13}C$ = $-39 \pm 0\,1$ per mille relative to Chicago Pee Dee Belemnite standard (ref 6)

The tritium value of our 1960 sample is exactly the same as the average of the samples from the northern hemisphere collected by Bishop *et al* during 1958 and 1959, although tritium in terrestrial surface water showed wide variations during this period A comparison of our carbon-14 value with results obtained by W. F Libby on atmospheric methane from 1952 shows no change greater than experimental errors Libby's samples contained 75 per cent and 60 per cent of modern carbon. They were collected in Britain by the British Oxygen Co, at Wembley, and submitted in the form of carbonate by H E Gluckauf We are grateful to Dr Libby for his unpublished results

Agreement of the results is better than might be expected in view of the possibility that artificial inactive methane and hydrogen from city gas, automobile exhaust, and other industrial sources might be present Limits on the amounts of such artificial gases present can be deduced from the measured value of the stable isotopes We are planning to make at least one measurement a year in the future

[6] Craig, H., *Geochim. et Cosmochim. Acta*, **12**, 133 (1957).

Our communication on the growth of the tritium content of free hydrogen in the atmosphere was written before the publication by Begemann and Friedman[1] of detailed measurements for the period 1954–56. These showed considerable seasonal variation, but no pronounced increase during the two years following the Castle test series. Their earliest determination in January 1954 before the Castle test series was $9 \cdot 18 \times 10^4$ tritium units compared with $1 \cdot 66 \pm 0 \cdot 097 \times 10^4$ tritium units found by Grosse *et al.*[2] in the spring of 1952. This obvious increase was concluded by Begemann and Friedman to be due to the Ivy test series of November 1952. Evidence for an earlier increase based on the value $0 \cdot 38 \pm 0 \cdot 125 \times 10^4$ tritium units obtained by Faltings and Harteck[3] in 1948–49 now appears to be refuted by the value of $3 \cdot 5 \times 10^4$ tritium units reported by Bainbridge, Suess and Friedman. It may be noted, however, that this value is more than twice that observed by Grosse in 1952. With three sets of observations indicating a substantial increase prior to the Castle tests, it is difficult to support the conclusion of Bainbridge *et al.* that such an increase is "unlikely".

Our measurements[4] of the tritium content of atmospheric methane collected at Wembley by the British Oxygen Company gave values ranging from $1 \cdot 59 \times 10^4$ to $3 \cdot 36 \times 10^4$ tritium units during the period October 1958 to February 1959, the average value being $2 \cdot 19 \times 10^4$ tritium units. One sample collected on December 7, 1959, had a value of $2 \cdot 85 \times 10^4$ tritium units and another collected on February 8, 1960, a value of $1 \cdot 59 \times 10^4$ tritium units. It is true that the present reported value ($1 \cdot 94 \times 10^4$ tritium units) falls within the range of values obtained by us, but to state that it "is exactly the same" as the average of our samples collected in the northern hemisphere during 1958 and 1959 may give the incorrect impression that short-term fluctuations are very small.

Furthermore, in addition to the considerable short-term fluctuations observed at Wembley, we found that the levels in the northern hemisphere stratosphere and in the southern hemisphere generally were all about $0 \cdot 8 \times 10^4$ tritium units, considerably lower than those at Wembley. The level in the southern hemisphere troposphere has also shown a continuous rise during 1953–58 when our measurements ceased.

It is clear, therefore, that though the future measurements proposed by Bainbridge *et al.* will give some useful information, a more comprehensive sampling programme would be necessary to unravel the origin and distribution of tritiated methane in the atmosphere.

ENGINEERING

A Novel Electrostatic Machine: the Corona Motor

We would like to direct the attention of readers to a new type of electrostatic motor which may find use in some specialized application. The operation of the motor demonstrates one of the fundamental properties of electrostatic fields, namely, motion of charge under the influence of a voltage gradient.

The motor is shown in Fig. 1 and consists of a disk, made from an insulating material, which is mounted on a spindle, and three pairs of electrodes mounted circumferentially around the disk. The electrodes are alternately connected to the positive and negative terminals of a source of high-voltage direct current. The diameter of the disk is 1·5 in., and a supply of 8–13 kV. is sufficient to operate the motor. The disk rotates either clockwise or anti-clockwise, depending on the direction in which it was started. When running freely in air with the axis turning in jewel bearings, speeds of up to 12,000 r.p.m. are attained.

During running of the motor a corona discharge takes place along the circumference of the disk and extends from each positive electrode towards the next negative electrode against the direction of rotation. The glow discharge increases in intensity and extent with increase in voltage until at a critical voltage flashover occurs between the electrodes.

We surmise that the operation of the motor can be explained as follows (Fig. 2): Consider that the voltage

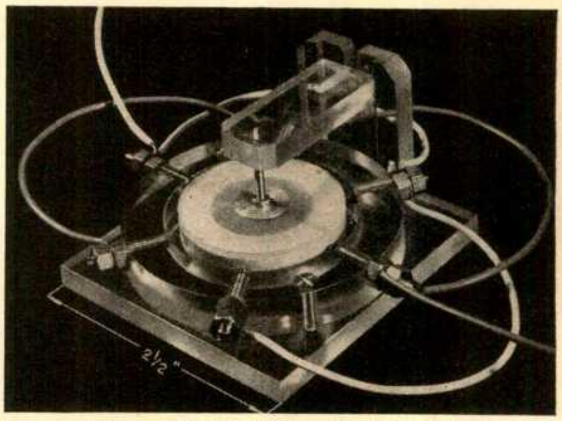

Fig. 1. Photograph of a six-electrode motor

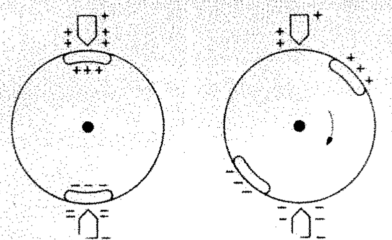

Fig. 2. *a*, Charge is deposited on the rim of the disk by ionization of the air gap. *b*, Disk rotates under action of torque developed by charge dipole

on the electrodes is increased until ionization of the air between the electrodes and the rim of the disk occurs, then a quantity of charge will be deposited on the rim (Fig. 2(*a*)). The charge, being of the same polarity as the electrode from which it emanated, is mechanically in unstable equilibrium with respect to the electric field, and if the disk is slightly disturbed, a couple will act on the disk, which will cause it to rotate, carrying the charge with it (Fig. 2 (*b*)). On reaching the opposite electrode, the charge is neutralized by a further ionized path in the air gap. If the process of charging and discharging carries on continuously, the disk will continue to rotate and will be able to deliver torque.

A possible explanation of why a glow discharge is noticed between alternate pairs of electrodes only is that a negative electrode deposits electrons on the disk, which creates an electric field between the charged area and the positive electrode. When the charged area is carried into the region where the resultant field intensity is large enough, ionization takes place. The positive electrodes, on the other hand, act as collectors of the negative charge. This results in a glow discharge between pairs of negative and positive electrodes only. At low voltages the ionization takes place close to the positive electrode and the region is extended for increased applied voltage until it covers the entire area between positive and negative electrodes. This is in conformity with the mechanism suggested, since the ionization will take place at a given field strength and thus the distance that separates the charged surface from the positive electrode, when ionization starts, will be determined by the magnitude of the charge.

In order to study the wave-forms of current when the motor is running, a small resistance was inserted in the earth lead, and the probe of an oscilloscope was connected across this resistance. It was found that charge transport takes place in short discrete bursts, of approximately 1 µsec. duration. The number of discharges a second depends on the speed of rotation, but a typical value is 2,000 discharges a second. Fig. 3 shows the wave-form occurring in a two-electrode motor.

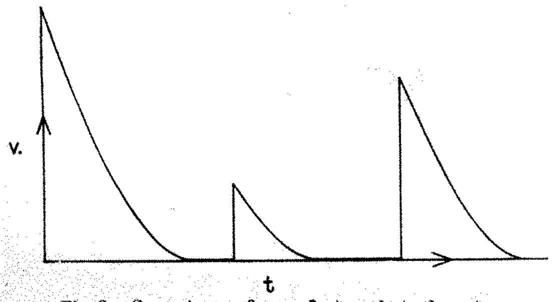

Fig. 3. Current wave-forms of a two-electrode motor

The corona motor is the converse of the Van de Graaf generator. In both cases charge is the active medium, but while in the Van de Graaf generator it is transported against an electric field to supply voltage, in the motor it is allowed to move with the field in order to supply torque.

The simplicity of construction and the absence of magnetic and metallic material might well justify further research to develop the motor into an efficient unit.

We wish to thank Mr. E. Fiedeldey for the mechanical construction of the device.

Rectifying Action of Non-uniform Fields in Dielectrics

PRELIMINARY work has been done on the breakdown of dielectric specimens under direct and 50 c./s. alternating voltages. With the latter a polarity detector was connected in series with the test specimen and in all cases point–plane electrode systems were used. For air and transformer oil a nickel-plated steel

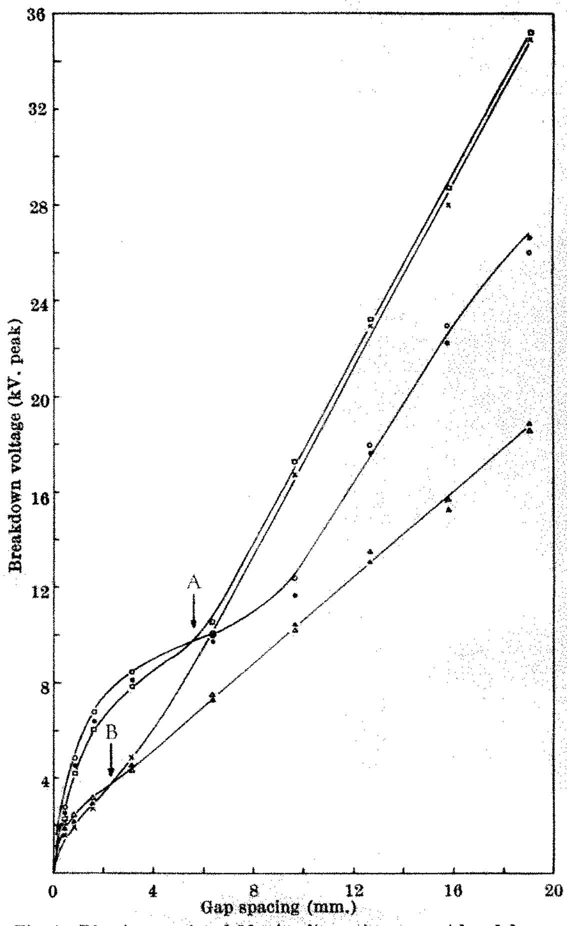

Fig. 1. Direct-current and 50 c./s. alternating-current breakdown voltage characteristics of air. Brass rod: □, negative point (d.c.); ○, positive point (d.c.); ●, 50 c./s. (a.c.). Nickel-plated point: ×, negative point (d.c.); △, positive point (d.c.); ▲, 50 c./s. (a.c.)

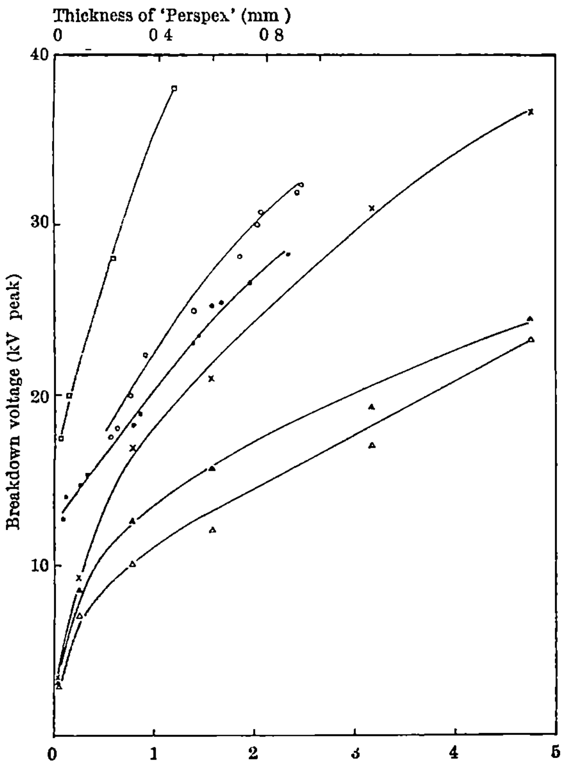

Fig 2 Direct-current and 50 c /s alternating-current breakdown voltage characteristics of 'Perspex' and transformer oil. Electrodes nickel-plated steel point–plane 'Perspex' □, negative point (d c), ○, positive point (d c), ●, 50 c /s (a c) Transformer oil ×, negative point (d c), △, positive point (d c), ▲, 50 c /s (a c)

sewing needle having a radius of curvature of about 2 5μ and a ⅛-in diameter brass rod having a radius of curvature of 1/16 in. were used in conjunction with a brass plate as the plane electrode. For 'Perspex' sheets the point electrode, a sewing needle similar to that described above, was pressed into the specimen at a temperature of 155° C and an aluminium foil was bonded to the other side of the specimen as the plane electrode. This assembly was then immersed in transformer oil All measurements were made under normal temperature and pressure conditions

It was observed that in 50 c /s. alternating fields breakdown of air always occurs when the point is at the positive half-cycle provided that the gap spacing is greater than the critical spacing shown at *A* and *B* in Fig 1 for the two different point electrodes The peak value of the alternating-current breakdown voltage is practically equal to the direct-current breakdown voltage with the point positive Breakdown under alternating voltages of either positive or negative polarity only occurs when the gap spacings are close to the critical value This polarity effect or rectifying phenomenon with large gap spacings is independent of the rate of rise of the applied voltage

This phenomenon also occurs in transformer oil and 'Perspex' as shown in Fig 2 Within the range of gap spacings under investigation the breakdown always occurs when the point is at the positive half-cycle In these two dielectrics other effects apart from the space charges may play an important part in the breakdown mechanisms The fact that the peak value of the alternating-current breakdown voltage in transformer oil is higher than the direct-current breakdown voltage with the point positive may be attributed to the effect of impurities The reversed tendency noted in 'Perspex' may be due to the thermal effect

The consistency of this phenomenon depends on the non-uniformity of the field, and the rectifying action, especially when air is used as the dielectric medium, can possibly be used to rectify high-voltage alternating currents

I wish to thank the Brush Electrical Engineering Co , Ltd , for permission to publish this communication

CHEMISTRY

Experimental Detection of Auto-Ionizing Transitions in Krypton by Electron Impact

A NUMBER of investigators[1] have discussed the contribution of auto-ionization to the shape of the ionization efficiency curves obtained by electron impact, but, at least in the case of the rare gases, no direct correlation has been found between the structure observed in these curves and the energy-levels known to be strongly auto-ionizing from ultra-violet absorption spectroscopy[2]. I wish to present ionization efficiency curves for the Kr^+ ion which exhibit discontinuities in slope at electron energies that lie quite close to the levels found in absorption. Both the intensity and separation of these levels fall off rather rapidly at higher energies, so that only those that lie directly above the normal $^2P^0_{3/2}$ ionization-level can be expected to be resolved Using the Paschen notation[3] for clearness in the figures; these levels are:

5 S'_1, 14 07 eV 6 S'_1, 14 25 eV 7 S'_1, 14 37 eV
4 S_2, 14 09 eV 5 S_2, 14 27 eV 6 S_2, 14 37 eV

Three independent determinations of the ionization efficiency curve for the Kr^+ ion are shown in Fig. 1 This figure is a photograph of the original recorder traces with the co-ordinate lines filtered out. The curves were obtained by the retarding potential method[4], which had been modified by the addition of a c signal detection, and an x–y recorder to obtain a continuous plot of the 'difference' ion current as a function of the electron energy The terms 'response 2', 'response 3', 'response 4' indicate that successively larger capacitance was introduced between the mechanically rectified output of the a c amplifier and the x–y recorder to improve the over-all signal to noise ratio. The scale for the 'difference' ion current (ordinate) is arbitrary and the divisions are unmarked since the zero of the y-axis amplifier was shifted between determinations to permit all three curves to be traced out on the same sheet of co-ordinate paper The electron energy scale has been shifted approximately 0·3 eV to place the onset of ionization to the $^2P^0_{3/2}$ level at its spectroscopic value of 14 0 (13 996) eV The electron energy was varied by a motor-driven helipot, and a signal proportional to it was impressed on the x-axis amplifier of the recorder A photographic enlargement of Fig 1 showing the onset of ionization and the break in the vicinity of the unresolved 5 S'_1 and 4 S_2 levels is given in Fig 2, and a similar enlargement showing the break near the 6 S'_1 and 5 S_2 levels in Fig 3 No clear break is to be found in the neighbourhood of the 7 S'_1 level on the curves presented in Fig. 1, and the curve labelled response 2 was not enlarged because of the high noise-level.

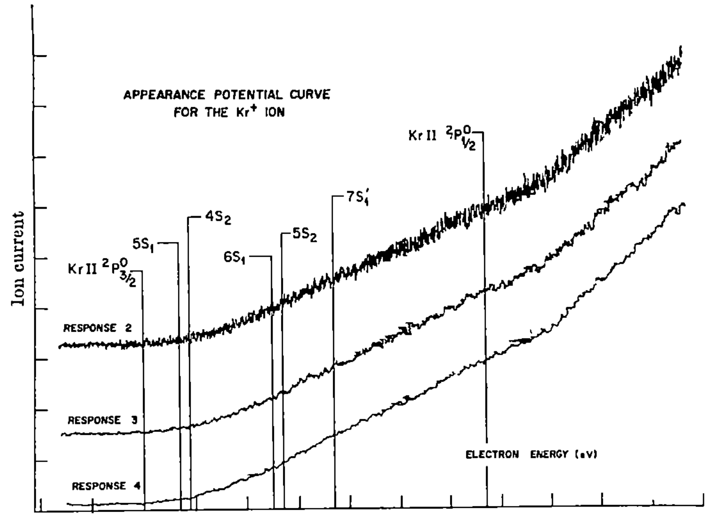

Fig. 1. Appearance of potential curves and auto-ionizing levels for the Kr$^+$ ion

These three curves were obtained a little more than a year ago for use in a paper describing the modification of the retarding potential method, which permitted the ionization efficiency curve to be plotted directly on the recorder paper as a continuous function of the electron energy. The toe of the curve was not examined critically at that time and the departure of the curve from linearity at about 0.15 eV above onset was a source of considerable disappointment. It was attributed to excessive curvature resulting from an abnormally large spread in the electron energy introduced by the square-wave modulation of the electron beam required for a.c. signal detection of the 'difference' ion current. Every effort was made to remove this 'curvature' by adjusting the position of the source magnet, the retarding potential, electrode voltages, etc., but it was not found possible to reduce it below that appearing in Fig. 1.

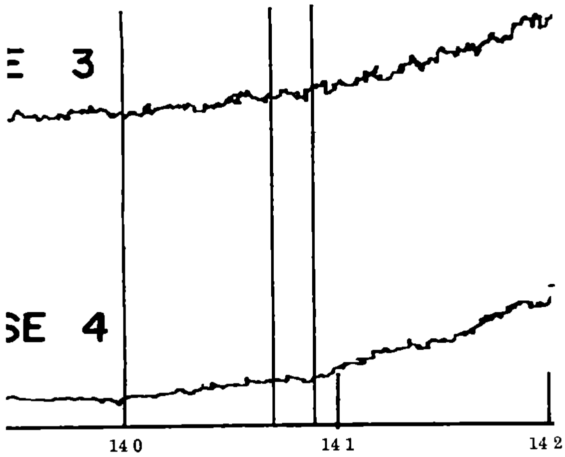

Fig. 2. Enlarged section of Fig. 1 showing the breaks at onset and near the location of the 5 S'_1 and 4 S_2-levels

Following the publication of a paper by Foner and Nall[5] on the structure found in the ionization efficiency curves of the rare gases, the curves shown in the figure were re-examined and the structure discussed earlier was found. Only a few other curves had been preserved, but on nearly all of these a break of some sort could be found near the first two pairs of auto-ionizing levels. These breaks were rather easily identified on five other ionization efficiency curves in addition to those shown in the graphs. Three of these latter showed a fairly strong indication of a break near the 7 S'_1 level. Since the measurements of these curves extended over a period of months and were obtained under different adjustments of the focus of the source, it seems hard to dismiss the agreement between these electron impact results and the spectroscopic data as accidental or instrumental. A more detailed report will be prepared as soon as the mass spectrometer used in this work becomes available again.

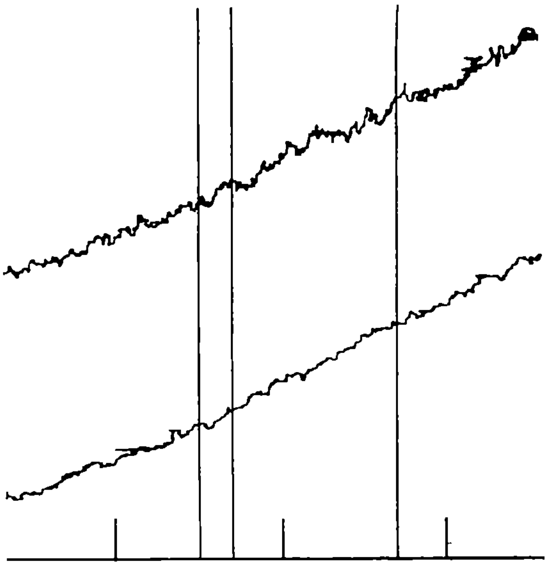

Fig. 3. Enlarged section of Fig. 1 showing the break near the 6 S'_1 and 5 S_2-levels

I thank Prof. W. R. S. Garton and Lady Anne Pery-Thorne for a very helpful discussion of auto-ionizing processes in general during a visit to the Imperial College of Science and Technology last autumn, and to Prof. Garton for pointing out that the auto-ionizing levels listed above as well as many others have been tabulated.

Surface Properties of Silver Iodide

It is a rather curious fact that both low-energy and high-energy surfaces abound, but intermediate energy surfaces of high area are infrequently found and have been little studied In a search of such intermediates, we recently examined the surface chemistry of silver iodide One method is to compare the apparent water specific surface area to the nitrogen area Another result which reflects the surface energy is the measurement of the heat of immersion in water and other liquids of particles of the solid sufficiently high in surface area to give meaningful results

Interest in the surface chemistry of silver iodide increases when one comes to recognize that silver iodide is regarded as hydrophobic[1] in classical colloid chemistry but as hydrophilic in cloud physics[2,3] When the double layer on silver iodide sols is repressed or destroyed, the colloid chemist finds that the particles flocculate quickly and settle out Yet this result may be due only to gravity and might have nothing to do with any hydrophobic character Previous results on the water vapour adsorption on silver iodide are quite contrary Birstein[3] claims some 130 layers of water are adsorbed before P_0 is reached It can be categorically stated that such a reported result is novel Solids adsorb at most 5–10 nominal layers before condensation is reached, as Harkins[4] showed years ago In a recent paper, Dubinin *et al* [5] also concluded that the silver iodide surface is hydrophilic and that it accepts about 3 layers before the condensation pressure

The cloud physicists regard silver iodide as the best 'cloud seeder' yet found presumably because its crystal parameters closely correspond to those of ice Observations of the nucleation and growth of ice crystals on single silver iodide crystals (colour motion pictures taken by Prof B J Mason, Imperial College, London) cast doubt on the concept of epitaxy For one thing, the ice crystals preferentially form at steps in the silver iodide crystal face where epitaxy cannot exist in all directions For another, the hexagonal pattern does not appear until the growing ice crystal has gained some size Finally, many ice crystals are formed on a single silver iodide crystal so that the epitaxy does not extend over the entire face as in the usual case

Some doubt was cast on the other direct measurements of the hydrophilic character of silver iodide by Halsey[7] in a brief note on the matter He concluded that ice and silver iodide surfaces are energetically incompatible although he was not considering cloud seeding at the time He was freezing xenon on to various crystals to attempt to produce energetically uniform adsorbent surfaces

Recent work in this Laboratory supports the contention that the silver iodide surface is rather hydrophobic For one preparation, the value of the ratio of the Brunauer–Emmett–Teller areas for water to nitrogen surface area measurements were $\Sigma H_2O/\Sigma N_2 = 7/100$, for another, $\Sigma H_2O/\Sigma Ar = 37/100$ For still another, $\Sigma H_2O/\Sigma N_2 = 27/100$ These results compare with the $\Sigma H_2O/\Sigma N_2 = 1/1{,}500$ obtained[8] for the almost completely hydrophobic graphitized carbon black, 'Graphon'

Further work is in progress to try to establish the surface characteristics of silver iodide For this purpose, high surface area samples in sizeable quantity are desired These are difficult to prepare, and then to outgas without severe sintering[7]

Our present hypothesis is that the steps in the silver iodide surface possess hydrophilic, possibly oxide, sites On these the water molecules first adsorb in clusters much as on 'Graphon' or graphites Eventually, when the nucleation process is carried out at low temperatures, the ice crystal structure develops

It seems reasonable to suspect higher sticking coefficient for the water on to earlier adsorbed molecules if they are not highly organized and 'busy' interacting strongly with the substrate This situation would probably prevail if water molecules could be adsorbed all over the surface as on an oxide This possible explanation of the efficacy of silver iodide is strengthened by the recent work of Eyring[9] on the sticking coefficient of many atoms and molecules on a number of surfaces He finds that the more ordered the molecules are in the surface, the lower is the sticking coefficient The molecules do not want to pay the 'entropy price' and thus more of them rebound

Possibly clays are good seeders because of the ion exchange sites which also build up water clusters, and proteins, reported by Vincent Schaefer to have excellent cloud seeding properties, are effective because of the separated polar sites at which water clusters can develop

We wish to thank the National Science Foundation for a grant in support of this work

Production of 'Active' Magnesium Oxide by heating in Vacuum

When samples of precipitated magnesium hydroxide were heated in air for a fixed period of 2 hr at a succession of temperatures ($T°$ C) Gregg and Packer[1] found that the specific surface area S (determined by the Brunauer–Emmett–Teller method with nitrogen at − 183° C) when plotted against T gave the curve I reproduced in Fig 1.

Conducting a similar experiment with starting material similarly prepared and having a similar specific surface (60 m^2 $gm.^{-1}$ as compared with 56 m^2 gm^{-1}), but heating *in vacuo*, we obtained curve II of Fig. 1 the temperature at which the maximal area was obtained has been lowered from *c* 390° C to *c* 300° C and the maximal area has been raised from 190 m^2 gm^{-1} to 340 m^2 gm^{-1}, which is unusually high for 'active' magnesium oxide

This effect of heating in air as compared with vacuum is qualitatively similar to that reported by Razouk and Mikhail[2] working with the mineral brucite, but their areas were considerably lower, and the

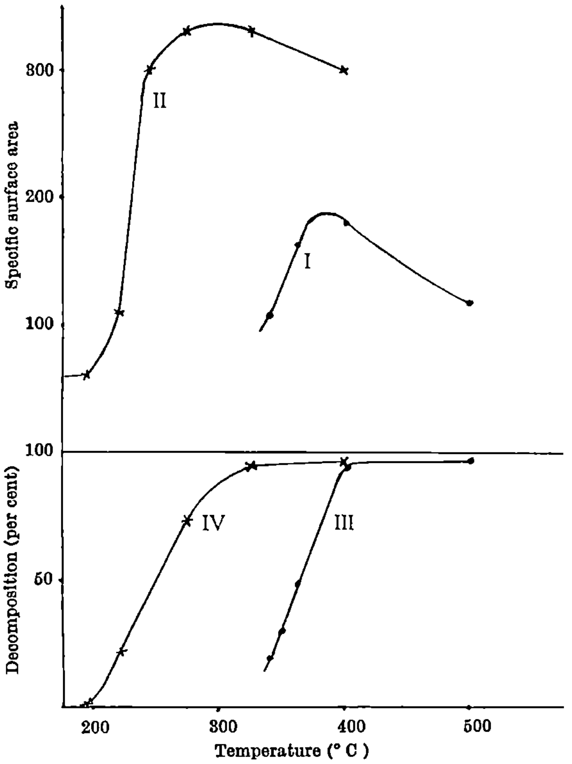

Fig 1 Calcination of magnesium hydroxide in air (curves I and III, see ref. 1) and *in vacuo* (curves II and IV, present work)

maximum was situated at a higher temperature (air, maximal area, 37 m^2 gm.$^{-1}$, at 500° C, vacuum, maximal area, 124 m^2 gm^{-1}, at 350° C) This is possibly due to the larger crystallite size of the mineral brucite as compared with precipitated magnesium hydroxide

An explanation of the superior 'activating' effect of heating in vacuum must await the results of experiments now in progress in this laboratory, but it is probably connected with the higher rate of decomposition *in vacuo*, and the reduction in sintering because of the lower temperature required for nearly complete decomposition (see curves III and IV)

Catalytic Decomposition of Ethylene on Nickel

The mechanism of the hydrogenation of ethylene on nickel has been studied intensively for at least thirty years; but there is still little agreement as to the exact nature of the intermediates present on the metal surface during the reaction On the other hand, examination of the chemisorption and dissociation of ethylene on nickel in the absence of gaseous hydrogen has been slight and mostly confined to ambient temperatures[1,2] This is surprising as the products and mechanism of ethylene dissociation can play an important part in hydrogenation, exchange and other reactions

The decomposition of ethylene on nickel has been studied as a function of temperature in the range −30° C to 200° C 14 8 gm of high-purity carbonyl nickel were loosely pressed into pellets ¼ in in diameter, reduced in a stream of hydrogen at 400° C for 6 hr and then evacuated at 400° C for 12 hr to a residual pressure of 1×10^{-6} mm Experiment showed that no hydrogen remained on the metal after this treatment. 6 mm of purified ethylene were then allowed to stand over the catalyst for a period of 4 hr at each of the temperatures studied, the volume of the system being about 130 c c. At the end of this period, the contents of the gas phase were condensed in a trap cooled in liquid nitrogen The non-condensable pressure was found to be due to methane The contents of the trap were analysed with a gas-chromatograph, using helium as carrier gas and a silica gel column The results are shown in Fig 1, in which the composition of the gas phase is plotted against the temperature of the catalyst.

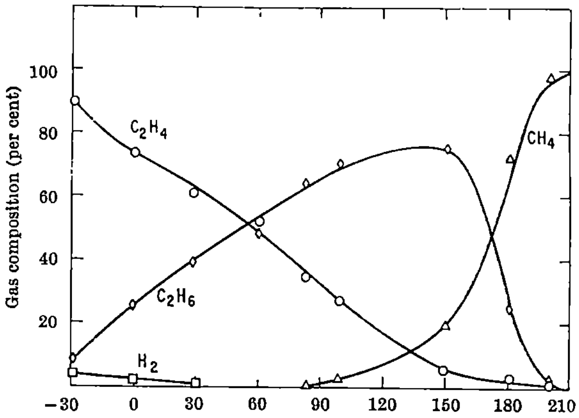

Fig 1 Temperature-dependence of the products of reaction of ethylene (6 mm pressure) with nickel after 4 hr Gas concentrations ○, C_2H_4, ◇, C_2H_6, △, CH_4, □, H_2

At temperatures below 60° C., the products are ethane and hydrogen, obtained by self-hydrogenation of the ethylene This effect has been studied at 20° C by Rideal and Jenkins[1], who suggest that ethylene in the gas phase reacts with chemisorbed hydrogen, obtained by dissociative adsorption of ethylene.

$$CH_2 = CH_2 \rightarrow \underset{*}{CH} = \underset{*}{CH} + \underset{*\,*}{HH}$$

The self-hydrogenation of ethylene was further studied by Beeck[3], who states that at −39° C. no ethane was produced. In the present work, however, appreciable quantities of ethane were found after reaction at −30° C and the rate of self-hydrogenation was found to be measurable down to − 78° C. The quantity of hydrogen evolved on self-hydrogenation was always small and less than 5 per cent of the ethane produced. No C_3, higher hydrocarbons or polymerization products were detected at low temperatures, this result is at variance with that of Morikawa *et al* [4], who found 29 per cent butane among the products at 0° C. Above 60° C, methane began to appear in the gas phase due to the cracking of ethylene and ethane present, the concentration of the latter decreased rapidly above 150° C and, at 200° C., the gas phase consisted entirely of methane.

The overall composition of the adsorbed residues on the surface can be calculated in the form $(CH_n)_x$, as shown in Fig 2 At 0° C, these residues have an

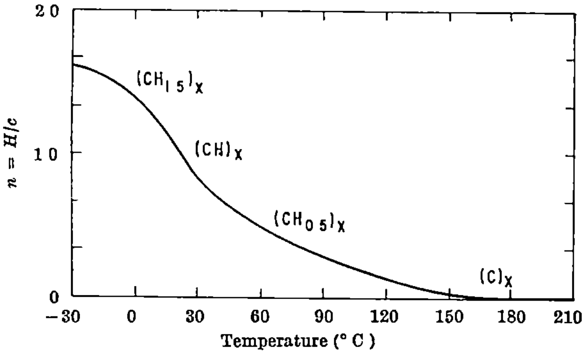

Fig 2 Temperature-dependence of overall composition of surface residues $(CH_n)_x$

average composition corresponding to $(CH_{1\ 5})_x$, but the value of n decreases rapidly with increasing temperature as hydrogen is progressively removed from the surface These observations agree with those of Rideal and Jenkins[1], who found that the residues had an average composition at 20° C approximating to that of acetylene, or $n = 1$ However, Pickering and Eckstrom[5] found no infra-red evidence for the presence of C—H bonds on the nickel surface under these conditions Sabatier[6] found that complete carbonization of nickel occurred with ethylene at 300° C , but it appears from the present work that the metal surface is essentially free of hydrogen at 200° C All adsorbed residues could be completely removed and the metal restored in activity by the reduction and evacuation procedure described here.

Role of Keto-Enol Tautomerism in the Polarographical Reduction of Some Carbonyl Compounds

DURING some polarographical investigations of certain α-aminoketones[1] and on the elimination of Mannich bases[2] experimental data were gathered, which can be explained by the occurrence of keto-enol transformation Though considerable attention has been paid to the mechanism of polarographical reduction of carbonyl compounds[3], no experimental evidence has been adduced for the participation of the keto-enol tautomerism in the reduction of the carbon–oxygen bond This follows from the fact that, in most cases examined, the keto form is the predominating form, and in buffered solutions used, establishment of keto-enol tautomeric equilibrium is fast However, the decrease of the limiting current of some keto acids has recently been interpreted[4] as being influenced by the keto-enol equilibrium in addition to hydration Experimental evidence for the role of enolization in the behaviour of substances like acetyl and acetonyl acetone[5] is unconvincing On the other hand, it has been discovered that the enolate form participates when anodic waves occur, corresponding to the formation of mercury salts, in alkaline solutions of enolizable ketones (Heyrovský, M , private communication) Keto-enol equilibria were involved also in the complicated and, in some ways, questionable scheme derived[6] for the reduction of thenoyl trifluoroacetone

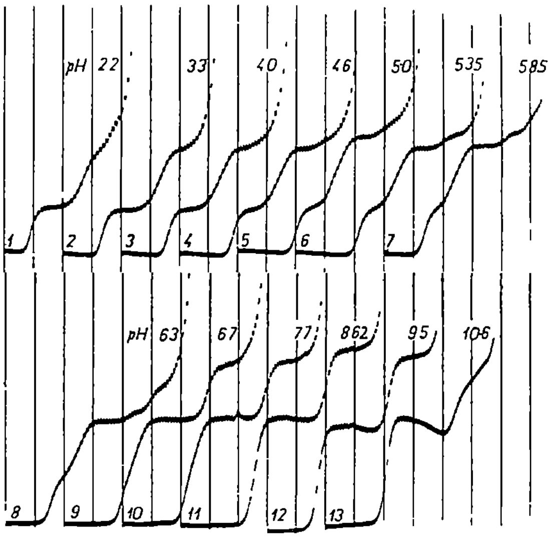

Fig 1 Dependence on pH of waves fo rphenyl vinyl ketone Britton–Robinson buffers, 1×10^{-4} *M* phenyl vinyl ketone Curves starting at 1–6, −0 4 V , 7–11, −0 6 V , 12 and 13, −0 8 V 200 mV (absc), saturated calomel electrode, $h = 56$ cm , $t_1 = 3\ 0$ sec , $m = 3\ 3$ mgm /sec., full-scale sensitivity, 2 0 μamp

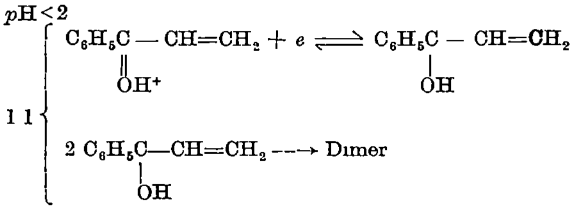
Since the conditions for detecting keto-enol tautomerism in solutions are unfavourable, we have focused attention on cases where the carbonyl compound is formed electrolytically at the surface of the electrode

As an example of such an electrode process the reduction of phenyl vinyl ketone is first mentioned In this case (Fig 1) a two-electron reduction occurs first in two one-electron steps in acid solution, followed by waves at more negative potentials. The half-wave potentials of the latter are practically identical with those for propiophenone The participation of keto-enol tautomerism is deduced from the dependence of the height of this more negative wave on pH and buffer composition It is assumed that irreducible enol formed as a reduction product in the first two-electron step is transformed by an acid-base catalysed reaction into the reducible keto form The rate of formation of the keto form from the enol form governs the limiting current of the more negative wave, which acquires a kinetic character The assumed irreducibility of the enol form is in agreement with the behaviour of stilbenes Stilbene itself is reduced at −2 3 V and the introduction of a hydroxyl group could result ($\rho^* = +\ 0\ 30$ V , $\sigma^I_{OH} = +\ 0\ 25$) in a shift of maximum by + 0 1 V.

Hence the mechanism of reduction can be depicted as follows



$$pH<2 \quad 1\ 1 \begin{cases} C_6H_5\underset{\underset{OH^+}{\|}}{C} - CH{=}CH_2 + e \rightleftharpoons C_6H_5\underset{\underset{OH}{|}}{C} - CH{=}CH_2 \\ 2\ C_6H_5\underset{\underset{OH}{|}}{C}—CH{=}CH_2 \dashrightarrow \text{Dimer} \end{cases}$$

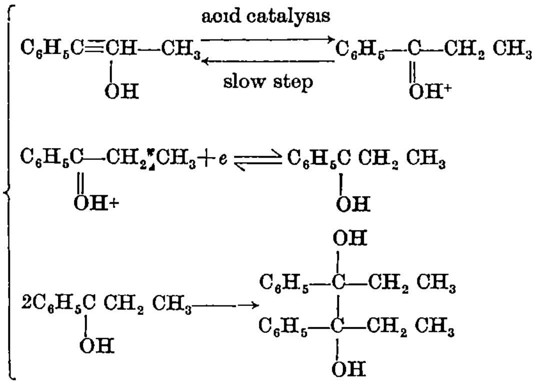
$$C_6H_5\underset{OH}{C}{-}CH{=}CH_2 + e \longrightarrow C_6H_5\,\underset{OH}{\overset{-\delta}{C}} \cdots CH \cdots \overset{-\delta}{CH_2}$$

$$C_6H_5\underset{OH}{\overset{-\delta}{C}} \cdots CH \cdots \overset{-\delta}{CH_2} + H^+ \longrightarrow C_6H_5\underset{OH}{C}{=}CH{-}CH_3$$

2 1



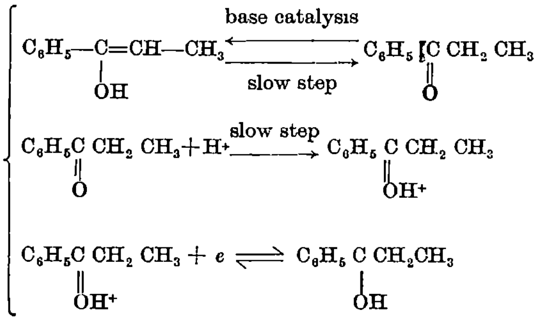
$$C_6H_5\underset{OH}{C}{=}CH{-}CH_3 \underset{\text{slow step}}{\overset{\text{acid catalysis}}{\rightleftarrows}} C_6H_5{-}\underset{\overset{\|}{OH^+}}{C}{-}CH_2\,CH_3$$

$$C_6H_5\underset{\overset{\|}{OH^+}}{C}{-}CH_2\,CH_3 + e \rightleftharpoons C_6H_5\underset{OH}{C}\,CH_2\,CH_3$$

$$2C_6H_5\underset{OH}{C}\,CH_2\,CH_3 \longrightarrow \begin{array}{c} OH \\ | \\ C_6H_5{-}C{-}CH_2\,CH_3 \\ | \\ C_6H_5{-}C{-}CH_2\,CH_3 \\ | \\ OH \end{array}$$

pH 4–6 Waves 1 1 and 1 2 identical as for $pH < 2$

2 1′



$$C_6H_5{-}\underset{OH}{C}{=}CH{-}CH_3 \underset{\text{slow step}}{\overset{\text{base catalysis}}{\rightleftarrows}} C_6H_5\,\underset{\overset{\|}{O}}{C}\,CH_2\,CH_3$$

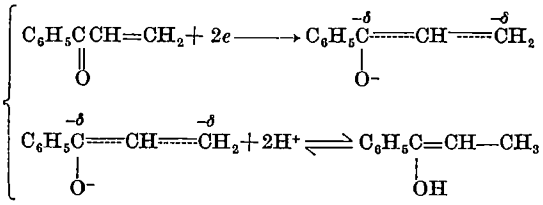
$$C_6H_5\underset{\overset{\|}{O}}{C}\,CH_2\,CH_3 + H^+ \xrightarrow{\text{slow step}} C_6H_5\,\underset{\overset{\|}{OH^+}}{C}\,CH_2\,CH_3$$

$$C_6H_5\underset{\overset{\|}{OH^+}}{C}\,CH_2\,CH_3 + e \rightleftharpoons C_6H_5\,\underset{OH}{C}\,CH_2CH_3$$

and dimerization as in 2 1

pH 6–9

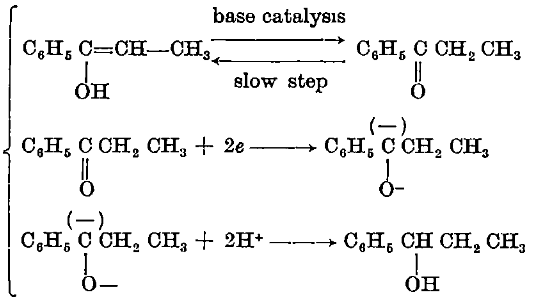
1 3



$$C_6H_5\underset{\overset{\|}{O}}{C}\,CH{=}CH_2 + 2e \longrightarrow C_6H_5\underset{O^-}{\overset{-\delta}{C}} \cdots CH \cdots \overset{-\delta}{CH_2}$$

$$C_6H_5\underset{O^-}{\overset{-\delta}{C}} \cdots CH \cdots CH_2 + 2H^+ \rightleftharpoons C_6H_5\underset{OH}{C}{=}CH{-}CH_3$$

2 3



$$C_6H_5\,\underset{OH}{C}{=}CH{-}CH_3 \underset{\text{slow step}}{\overset{\text{base catalysis}}{\rightleftarrows}} C_6H_5\,\underset{\overset{\|}{O}}{C}\,CH_2\,CH_3$$

$$C_6H_5\,\underset{\overset{\|}{O}}{C}\,CH_2\,CH_3 + 2e \longrightarrow C_6H_5\,\underset{O^-}{\overset{(-)}{C}}\,CH_2\,CH_3$$

$$C_6H_5\,\underset{O-}{\overset{(-)}{C}}\,CH_2\,CH_3 + 2H^+ \longrightarrow C_6H_5\,\underset{OH}{CH}\,CH_2\,CH_3$$

The factors governing the dependence of the limiting current on pH are, in acid solutions, the rate of the acid-catalysed ketone formation, in medium pH-range, either the rate of the base-catalysed ketone formation or of the protonation of the ketone formed, and finally at higher values of pH, base catalysis of the ketone formation.

Essentially the same explanation applies also for the dependence on pH of the limiting currents of acetophenone, when it is formed from $C_6H_5\,CO\,CH_2{-}X$ (X = halogen, NR_3^+, OR, SR, etc) observed by Zuman and Horák[1] and Lund[7] The enolate ion $C_6H_5\,CO\,CH_2(-)$ formed in the first step accepts a proton more quickly on oxygen than on carbon, and the polarographically inactive enol $C_6H_5\,C\,(OH){=}CH_2$ is thus the predominating form in the first reduction step

This enol is transformed either by an acid-catalysed reaction into the protonized form (2 1), when an increase of the one-electron wave with decreasing pH is observed, or by a base-catalysed reaction (2 1′), with subsequent protonation of the ketone formed The rates of ketone formation and protonation being comparable, the resulting current first increases and then decreases with increase of pH (Fig 2*b*). The decreasing part of this dependence, limited by the rate of protonation, is identical with that found for acetophenone Finally, the unprotonized keto form due to reaction catalysed by a base can be reduced in a two-electron step (2 3) at more negative potentials

In accordance with this supposition the dependence on pH of the more negative wave is little affected by

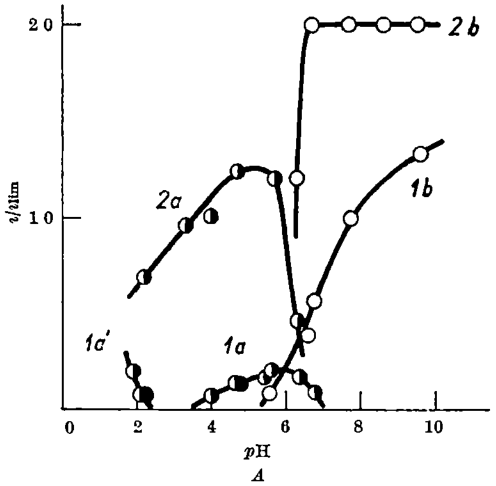


Fig 2 Dependence on pH of limiting currents
The more negative wave for phenyl vinyl ketone (1*a*, 1*b*) compared with waves for propiophenone (2*a*, 2*b*) 1*a*, 2*a*, one-electron wave, 1*b*, 2*b*, two-electron wave

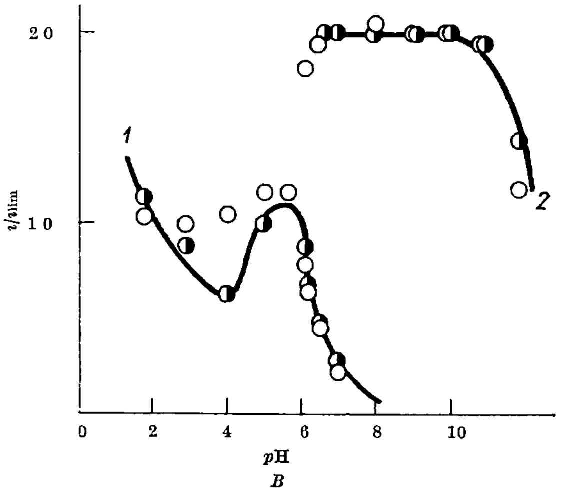

Fig 2 Dependence on pH of limiting currents
The more negative wave for ω-propiophenone methoiodide (halved circles) compared with waves for propiophenone (circles) 1, One-electron wave, 2, two-electron wave

the nature of X in C_6H_5 CO CH_2—X, but depends both on substitution in the phenyl ring and on the methylene group[1,7]

The course of the reduction of phenyl vinyl ketone is also consistent with the idea that the reduction of the protonized form leads to inactive C_6H_5 CH(OH)CH $=CH_2$, while that of the unprotonized form leads to C_6H_5 CO CH_2 CH_3 The increase in height of the wave would be a function of rate of proton transfers only, but this would scarcely explain the increase of the propiophenone wave in acid media

The effect of keto-enol tautomerism on the polarographic curves of ketones formed at the dropping mercury electrode is being investigated further

BIOCHEMISTRY

Modification of the Properties of Flour Protein by Thiolated Gelatin

Recently, both Hird's group[1] and Mecham *et al* [2,3] have suggested that many characteristic properties of dough may be accounted for by postulating that the flour proteins participate in sulphydryl–disulphide interchange reactions Sokol and Mecham[4] have pointed out, however, that there is as yet no direct evidence that such reactions do occur in dough Thus further evidence bearing on this attractive hypothesis is desirable

As a contribution to this question we have examined the effect of directly adding, to dough, protein containing sulphydryl groups For this purpose we have used gelatin with —SH groups 'built in' by the thiolation procedure of Benesch and Benesch[5], comparing this thiolated protein with normal gelatin which has a negligible content of sulphydryl groups

The effect on some of the physical characteristics of dough was examined by stretching the doughs on an extensometer, thus obtaining load-extension curves (cf Halton[6]) Secondly, using these doughs, determinations were made of the content of hydroxyproline in the gluten, as this insoluble protein complex is primarily responsible for the rheological behaviour of dough Since there is about 14 5 per cent hydroxyproline in the gelatin and none in normal gluten, its presence would indicate an association in the gluten of flour proteins and gelatin

Unyeasted doughs were made by mixing 28 gm. flour with sodium chloride solution (2 5 per cent) Gelatin, thiolated gelatin or other substances to be added were dissolved in the salt solution immediately before adding it to the flour After mixing, the doughs were rested for 1 hr and then stretched on the extensometer These operations were carried out at 26 6° C Glutens were then washed from the doughs with warm water and hydrolysed with acid The neutralized hydrolysates were dissolved in 0·1 *M* citrate buffer, *p*H 2 2, and then passed through a column of 'Zeokarb 225' to separate hydroxyproline from tyrosine, which interferes in the determination Hydroxyproline was determined, in the appropriate fraction from the column, by the method of Neuman and Logan[7]

The extensometer measurements showed that with freshly prepared samples of thiolated gelatin the extensibility of the dough was increased and the elasticity decreased, as compared with the control doughs In the control experiments with normal, unthiolated gelatin no significant changes in the load-extension curves were observed Following Benesch and Benesch, the preparation of thiolated gelatin had been passed through a column of 'Amberlite 400' to remove any *N*-acetyl homocysteine formed during the thiolation reaction It is to be presumed, therefore, that the observed modification of the physical properties of dough were not due to traces of this compound but to protein sulphydryl

As additional control experiments we have also made doughs containing mixtures of normal gelatin with respectively cysteine, homocysteine, partially hydrolysed *N*-acetyl homocysteine thiolactone, and determined the hydroxyproline content of the gluten from these doughs The results in Table 1 show the quantity of gelatin 'bound' per 28 gm flour, as calculated from the content of hydroxyproline in the various gluten hydrolysates

Table 1

Additions to dough (28 gm flour)	Gelatin added to dough (mgm)	Gelatin 'bound' to gluten (mgm)
Normal gelatin	156	5
Normal gelatin	156	5
Thiolated gelatin	160	60
	80	38
Gelatin and homocysteine	156	7
Gelatin and cysteine	156	6
Gelatin and partially hydrolysed	160	6
N-acetyl homocysteine thiolactone	160	8

These results show that while a significant proportion of the thiolated gelatin becomes firmly associated with the gluten, this degree of binding is not observed with gelatin or with mixtures of gelatin and —SH compounds of low molecular weight The evidence at present is insufficient to decide whether this is due to interchange reactions leading to the formation of mixed flour protein–gelatin disulphides or whether it is due to the association of the thiolated gelatin by other mechanisms, for example, by hydrogen bonding, or formation of insoluble disulphide gelatin Experiments are in progress which it is hoped will provide further evidence on this question.

Separation of Low Molecular Weight Peptides from Amino-Acids on 'DEAE-Sephadex'

METHODS are now available for the separation of amino-acids from peptides, with a molecular weight greater than 1,000, by molecular sieving on cross-linked dextran gels[1,2] However, the separation of peptides of lower molecular weight from all their constituent amino-acids is often difficult because of their similar physical properties Recently I described a method for the separation of neutral amino-acids from neutral peptides of low molecular weight on the anion exchanger 'Dowex-1' with ammonium acetate buffer pH 8 65 (ref 3) At this pH the monoaminomonocarboxylic acids, which all have pK values for the amino group greater than 9 0, are predominantly in the neutral form, whereas many peptides of these amino-acids have pK values less than 8 3 and thus are predominantly in the anionic form (pK values from Cohn and Edsall[4]) This method had the disadvantages that the aromatic amino-acids were strongly adsorbed on the resin, and that traces of amino-acids contaminated the peptide fraction

An improved method is now described using the anion exchanger 'DEAE-Sephadex', with collidine acetate buffer and a pH gradient elution Rudloff and Braunitzer[5] used this buffer and 'Dowex-1' resin for the fractionation of peptides from a partial hydrolysate of hæmoglobin This buffer system has several advantages over the ammonium acetate solution used in the earlier method. It gives better control of pH, is more volatile, and does not interfere with the estimation of amino-acids and peptides by the ninhydrin reagent[6] By using a pH gradient elution it is possible to separate neutral peptides from acidic amino-acids Mixtures of pyridine and acetic acid have been recommended as solvents for separation by molecular sieving on 'Sephadex' and 'DEAE-Sephadex' (ref 2)

There are also advantages in using the diethyl-amino-ethylether (DEAE) derivative of cross-linked dextran gel rather than the quaternary ammonium derivative of polystyrene DEAE exchangers have a reasonably high capacity in the pH 8 region[7] With 'DEAE-Sephadex' the functional groups are mainly inside the gel grains, and thus when they are charged, ions of opposite charge will be repelled from the grains Porath and Lindner[2] showed that aromatic compounds, which are strongly adsorbed on polystyrene resins and dextran gels, can be effectively fractionated on 'DEAE-Sephadex', since intimate contact with the strong adsorption centres is avoided. Hence, a separation of aromatic amino-acids from peptides should be possible on this material.

To illustrate the use of this method, a mixture of a typical tripeptide, DL-leucylglycylglycine, and twelve common L-amino-acids was fractionated and the result is shown in Fig 1 'DEAE-Sephadex' A25 (Pharmacia, Uppsala, Sweden, Lot No *To*7871M, particle size 100–270 mesh) was cycled with 0 5 M hydrochloric acid and 0 5 M sodium hydroxide and converted to the acetate form with 0 5 M acetic acid A column 20 cm × 1 cm diameter was thoroughly equilibrated with 0 1 M collidine (2,4,6,-trimethyl-pyridine) acetate buffer pH 8 55, prepared from water free from carbon dioxide The amino-acids were each approximately 2 5 mM and the peptide 5 0 mM in the buffer with the pH adjusted to 8 45 Cystine, which would be eluted with the peptide, was first partially oxidized to cysteic acid by treating 1 0 ml of the mixture with 0 05 ml 30 per cent hydrogen peroxide and evaporating to dryness, *in vacuo*, in less than 10 min at room temperature The mixture was transferred to the column with 1 5 ml buffer A total of 20 ml of buffer was placed between the top of the column and the mixing chamber, which contained 150 ml buffer Elution was started and a gradient in pH established using 0 1 M acetic acid until fraction No 45, when 1 0 M acetic acid was used Fractions of 2 5 ml volume were collected at a rate of 11/hr The temperature was 30° C (room temp) From each fraction 0 5 ml was analysed by the quantitative ninhydrin reagent[6], and the results expressed as leucine equivalents (μmoles per fraction) The pH of each fraction was determined (some absorption of carbon dioxide occurred in the more alkaline fractions while they were in the collector, causing a slightly low value for the pH) The amino-acid composition was determined by paper chromatography

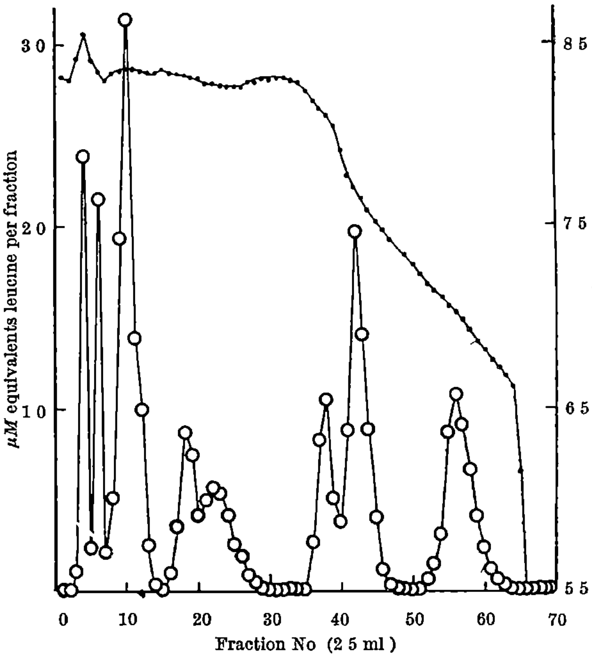

Fig 1 Separation of DL-leucylglycylglycine from L-amino-acids on a column of 'DEAE-Sephadex' A25 (for details see text) ○, total ninhydrin colour of fraction expressed as μM equivalents of leucine, ●, pH of fraction, Peak 1, lysine, 2, proline (as μM proline), 3, alanine, glycine, valine, leucine, 4, serine, 5, phenylalanine, 6, tyrosine, 7, leucylglycylglycine, cystine, 8, glutamic acid, aspartic acid

The amino-acids were eluted from the column in the order expected from the pK values of their amino groups[4] The aromatic amino-acids were adsorbed to some extent but not so strongly as on the 'Dowex-1' resin Only fraction No 40 contained both tyrosine and leucylglycylglycine Their separation would be improved by re-running and taking smaller fractions. As the pH value of the eluant fell below 7 9 the peptide began to emerge. Cystine, because of its slightly acidic character, emerged with the peptide. It was possible to remove only 46 per cent of the cystine by the oxidation procedure used More vigorous oxidation may damage other amino-acids[8]. However, cystine can be easily removed from most peptides by partition chromatography When some other neutral peptides

DL-alanylglycine, DL-alanyl-DL-alanine, DL-alanyl-DL-methionine, DL-alanylglycylglycine, glycylglycine, diglycylglycine, glycl-L-leucine and glycyl-L-tryptophan) were chromatographed on this system, they also emerged when the *p*H value of the eluant fell below 8 0 No difficulty was experienced with the aromatic peptide glycylphenylalanine

With the earlier method[3] carbon dioxide was found to interfere with the separation, and the formation of carbamino-acids was suggested to explain the presence of amino-acids in the peptide fraction However, using 'DEAE-Sephadex' it was possible to separate leucine from glycylglycine with 0 1 *M* collidine carbonate buffer *p*H 8 5 This matter is being investigated in greater detail Recently the separation of amino-acids and peptides on DEAE-cellulose with carbonic acid was reported[8].

I wish to thank Prof T F Dixon for his criticism of the manuscript, Dr R L M Synge for his interest and encouragement of this work, and S Kanason for technical assistance

Demonstration and Some Properties of Peroxidase in Pig Thyroid Gland

ALTHOUGH it has been postulated by various authors[1,2] that the thyroid contains a peroxidase which plays an essential part in the synthesis of organically bound iodine, the available data do not seem to be sufficient to prove its presence This communication submits distinct evidence for the presence of peroxidase in pig thyroid tissue, especially in its microsomes

In this work an assay[3] employing guaiacol instead of iodide as a hydrogen donor was used, since this method is not only sensitive and convenient to carry out but also makes it possible to obtain the initial rate of reaction, which is difficult to measure using iodide as a hydrogen donor Peroxidase activity in the preparation was expressed in terms of specific and total activity (see Table 1)

It was found by this assay method that thyroid homogenate always revealed fairly strong peroxidase activity although the activity varied considerably from preparation to preparation The activity in the homogenate disappeared entirely after boiling for 2 min.

Table 1 INTRACELLULAR LOCALIZATION OF PEROXIDASE IN PIG THYROID

Pig thyroid slices were washed repeatedly with 0 9 per cent sodium chloride solution, blotted with filter paper, and a 10 per cent tissue suspension was homogenized in a 0 25 *M* sucrose solution using a Waring blender Sediments obtained by differential centrifugation were dispersed uniformly in phosphate buffer, *p*H 7 0 The enzyme assay system contained 1 0 ml of 0 1 *M* phosphate buffer, *p*H 7 0, 1 0 ml of 0 1 *M* guaiacol an adequate amount of the tissue fraction, 0 027 ml of 0 03 *M* hydrogen peroxide, and water to a final volume of 3 03 ml The over-all reaction was followed by a Beckman spectrophotometer at 20° C by measuring the absorbance at 470 mμ (ref 3) One unit of peroxidase activity is defined as an increase in absorbance of 1 0 per sec under the conditions specified above Specific activity refers to the number of units per mgm of nitrogen

Fraction	Preparation	Specific activity (milli-units per mgm nitrogen)	Total activity (milli-units per gm wet tissue)
Homogenate	*a* *b*	12 5 9 5	250 102
Sediment 700*g*, 10 min (nuclei)	*a* *b*	19 0 9 5	24 0 31 0
Sediment 5,000*g*, 10 min (mitochondria)	*a* *b*	16 3 23 6	12 1 11 3
Sediment 80,000*g*, 30 min (microsomes)	*a* *b*	77 0 68 1	58 5 63 0
Supernatant 80,000*g*, 30 min	*a* *b*	2 2 0 9	17 5 6 1

a refers to experiments that started from pooled glands of seven pigs, *b* from ten pigs

The distribution of peroxidase activity in the subcellular fractions is given in Table 1, which shows that both specific and total activity are greatest in the microsomal fraction Appreciable activity was also found in the nuclear and mitochondrial fractions, but this is thought to be attributable to unbroken cells and concomitant microsomes, respectively The activity due to contaminating hæmoglobin in the particulates was estimated to be negligibly small on the basis of the measurement of the amount of hæmoglobin contained in the preparations and of the peroxidative activity of crystalline horse hæmoglobin under the same conditions

The microsomal peroxidase was found to have the following properties (1) The Lineweaver–Burk plot at a constant concentration of guaiacol (33 m*M*) was linear in the range of the concentration of hydrogen peroxide, 0 3–0 03 m*M* Beyond a concentration of hydrogen peroxide of 0 4 m*M*, distinct inhibition was observed, increasing with the increase in the hydrogen peroxide concentration The Lineweaver–Burk plot at a concentration of hydrogen peroxide of 0 27 m*M* was linear in the range of the concentration of guaiacol studied (64–0 9 m*M*) (2) The *p*H optimum was about 8 6 under the conditions of the standard assay system except in the case of *p*H. (3) The enzyme was inhibited by potassium cyanide, sodium azide, and sodium fluoride, in such a way that the percentage inhibition versus the logarithm of the concentration of each reagent represented a sigmoid curve of the first order The concentrations for 50 per cent inhibition were $2\ 2 \times 10^{-6}$ *M*, $1\ 3 \times 10^{-5}$ *M* and $5\ 8 \times 10^{-3}$ *M*, respectively The inhibition by cyanide was caused, on the basis of kinetic study, by the competition with hydrogen peroxide for the enzyme These facts suggest that the enzyme is probably a hæmoprotein, as are other known peroxidases (4) The enzyme was completely inhibited by thiouracil and 3-amino-1,2,4-triazole at a concentration of 2 m*M*, whereas it only partially inhibited by the same concentration of potassium perchlorate and potassium thiocyanate

It was found that the microsomal peroxidase was rendered soluble by treatment with 1 per cent digitonin for 40 min at 2° C This enzyme was further purified about two-fold by salting-out with ammonium sulphate between 40 and 60 per cent saturation. The purified enzyme revealed practically the same properties as the one bound in the microsomes.

The partially purified enzyme preparation was able to catalyse, in the presence of enzymically generated hydrogen peroxide, the incorporation of substrate amount of iodide into thyroglobulin as efficiently as thyroid particulate fraction did[4] It was also possible (unpublished observations of Dr M Suzuki of this Institute) for the enzyme preparation to catalyse the iodination reaction of tyrosine under the experimental conditions of Alexander[2] These results seem to show that the thyroid peroxidase dealt with in this communication catalyses the peroxidation of iodide and probably plays an important part in the hormone synthesis in thyroid tissue

We thank Dr M Suzuki of this Institute for carrying out one of the experiments

Transaminase Activity in Arterial Tissue of the Rabbit

Rinehart and Greenberg[1,2] observed a marked thickening of the intima and deposition of lipid in pyridoxine-deficient monkeys Though the role of pyridoxine as an essential co-factor in fat and protein metabolism has been well established, the precise mechanism of atherogenesis in pyridoxine deficiency has not been elucidated Goswami and Sadhu[3] have adduced evidence tending to show that the hypercholesterolæmia of pyridoxine deficiency is not related to impairment of formation of arachidonic acid. The possibility that atherogenesis may be a consequence of defective formation and maintenance of collagen and elastic tissue brought about by decreased transaminase activity therefore gains added importance However, while the transaminase activities of several tissues, both under normal and pathological conditions, have been examined, very little work has been reported on the transaminase activity of arterial tissue The present communication reports the demonstration of significant transaminase activity in arterial tissue

Adult male rabbits weighing approximately 1 kgm were killed, and different segments of arterial tissue dissected out, homogenized in a Potter–Elvehjem homogenizer at 0° C with disodium phosphate (0 1 M) buffer of *p*H 7 4, and centrifuged at 2,500 r p m for 10 min in the cold The supernatant was examined for transaminase activity Portions were incubated with different L-amino-acids (glutamate, aspartate and alanine) as amino donor and α-keto acids (α-ketoglutarate, oxaloacetate and pyruvate) as amino acceptor. The incubation mixture for the assay of enzyme activities consisted of 1 0 ml of crude extract (0 3 mgm nitrogen/ml), 0 2 ml of 0 1 M amino donor and 0 2 ml of 0 2 M amino acceptor The samples were incubated for 1 hr at 37° C The protein was precipitated by boiling the samples for 10 min , cooling and then adding acetone to 5 ml volume The samples were centrifuged and 0 04 ml of the supernatant fluid was taken for paper chromatographic determination of amino-acid in the reaction product (Table 1)

High transaminase activity was noticed with aspartate + α-ketoglutarate and with glutamate + oxaloacetate No transaminase activities were noticed with glutamate + pyruvate, aspartate + pyruvate, alanine + α-ketoglutarate or alanine + oxaloacetate

Table 1 TRANSAMINATION OF DIFFERENT L-AMINO-ACIDS WITH α-KETO ACIDS

Amino donor	Amino acceptor	Amino-acid formed
Aspartate	α-Ketoglutarate	Glutamate
Alanine	α-Ketoglutarate	Nil
Glutamate	Oxaloacetate	Aspartate
Aspartate	Oxaloacetate	Nil
Aspartate	Pyruvate	Nil
Glutamate	Pyruvate	Nil

The variation in transaminase activity within the *p*H range 4 0–10 0 was examined using aspartate and α-ketoglutarate The optimum *p*H was found to be between 7 0 and 8 0, maximum transamination of the keto-acid was observed after 30 min of incubation, with no further increase thereafter. Ageing of the extract at room temperature (30° C) for 4–6 hr or in the refrigerator for 4–5 days did not lower the transaminase activities appreciably

The transaminase activity was found to be inhibited after pre-incubation of the extract (at 37°) with *p*-chloromercuric benzoate (10^{-4} M), mercuric chloride ($5 \times 10^{-5} M$) and silver nitrate (5×10^{-5} M). But when incubated with cysteine, *p*-chloromercuric benzoate could not inhibit the transaminase activity Enzyme activity was unaffected by pre-incubation with deoxypyridoxine (10^{-4} M), potassium cyanide (10^{-4} M), hydroxylamine hydrochloride (10^{-4} M), 2,4-dinitrophenyl hydrazine (10^{-4} M), 8 0 oxiquinoline (10^{-4} M) and penicillamine (10^{-4} M)

Detailed work dealing with the co-factor requirements, purification, kinetics and other properties of the transaminase system in normal and atherosclerotic arterial tissues will be reported elsewhere

I am grateful to Dr J C Ray, director of this Institute, and to Dr A Narayanaswami for their interest in this work

Interaction of ^{14}C-Œstrone with Tryptophan in the Presence of Peroxidase

IN 1955, Stotz *et al* [1] discovered an œstrogen-sensitive peroxidase in rat uterus and later these workers[2] found that those tissues which had a high rate of cell renewal also had high peroxidase activity This enzyme may therefore play a significant part in cell proliferation and growth, and it was thought of interest to investigate its effect on œstrogens, using initially the very stable and more readily available horseradish enzyme In preliminary experiments[3] it has already been shown that œstrone and other phenolic œstrogens could interact with protein and certain amino-acids when incubated with peroxidase under aerobic conditions, and the present communication deals with this reaction involving tryptophan

(16–^{14}C)œstrone (4,000 c p m in 10 μgm) dissolved in 5 ml phosphate buffer *p*H 7 4 was incubated under oxygen with tryptophan (3×10^{-3} M), manganese chloride (10^{-5} M) and horseradish peroxidase (10 μgm), for 5 hr at 37° C with constant shaking, and the amount of radioactivity remaining in the aqueous medium after extraction with ether was determined This was repeated under various experimental conditions In addition, each ethereal fraction was examined for œstrone or its metabolites by chromato-

Table 1 PERCENTAGE CONVERSION OF ^{14}C-ŒSTRONE TO WATER-SOLUBLE ETHER-INSOLUBLE PRODUCTS BY PEROXIDASE IN THE PRESENCE OF TRYPTOPHAN UNDER VARIOUS EXPERIMENTAL CONDITIONS

Experimental conditions	Percentage of added radioactivity remaining in aqueous medium after extraction with ether
Normal incubation*	61 5 68 5
$MnCl_2$ omitted	4 8 5 5
Tryptophan omitted	1 1 1 0
Peroxidase solution boiled	1 6 1 2
Anaerobic incubation	0 8
Incubated with KCN (10^{-3} M)	0 5
Incubated with sodium azide (10^{-2} M)	14 5
Incubated with sodium iodoacetate (10^{-}[illegible] M)	57 3
Incubated with catalase (100 μgm)	1 1
Kynurenine substituted for tryptophan	5 5
$MnCl_2$ omitted and incubated with H_2O_2 (2×10^{-5} M)	14 2
$MnCl_2$ omitted, kynurenine substituted for tryptophan and incubated with H_2O_2 (2×10^{-5} M)	13 8
Tryptophan added after incubation and solution immediately extracted with ether	2 2
^{14}C-Œstrone added after incubation and solution immediately extracted with ether	2 0

* Incubation mixture peroxidase, 10 μgm , œstrone, 10 μgm , $MnCl_2$, 10^{-5} M, tryptophan, 3×10^{-3} M, in 5 ml

graphy[4] followed by autoradiography[5] The anaerobic incubation was carried out in an evacuated Thunberg tube.

The results in Table 1 show that horseradish peroxidase, in the presence of tryptophan, is able to convert œstrone to water-soluble ether-insoluble metabolites in high-percentage yields No such products were formed in the absence of this amino-acid and only unchanged œstrone could be detected in the ethereal fraction, showing that tryptophan was directly involved in the reaction and was not merely acting as a carrier No water-soluble compounds were formed when tryptophan or œstrone was added only after incubation and the solutions immediately extracted with ether, and there is evidence that the tryptophan molecule was altered during the reaction This was indicated by the yellow colour of the solution after incubation and the change in ultra-violet spectrum, and was confirmed by chromatography

The reaction was dependent on manganese ions and was abolished under anaerobic conditions or on boiling the peroxidase solution Cyanide and azide, which are known to affect iron-containing enzymes, were also found to be inhibitory, but iodoacetate, which combines with sulphydryl groups, had no effect

The marked inhibition by catalase suggests that hydrogen peroxide is involved in the reaction and although added hydrogen peroxide in the absence of manganese was not very effective, even at concentrations above 2×10^{-5} M, the results agree with the findings of Knox and Mehler[6], who showed that only slowly generated peroxide could be utilized efficiently for the breakdown of tryptophan by liver peroxidase-oxidase Kynurenine, an oxidation product of tryptophan, which is not known to generate hydrogen peroxide with peroxidase, gave only very low results, but with added peroxide the yield of water-soluble products was as high as with the parent amino-acid

These results suggest that horseradish peroxidase, acting as an aerobic oxidase, can utilize tryptophan to generate hydrogen peroxide and that afterwards, behaving like a true peroxidase, it converts œstrone to metabolites which interact with this amino-acid or its oxidation products However, the final proof for this hypothesis must await the isolation and identification of the water-soluble complexes and it is also hoped to determine their physiological activity

Auxin Activity in Ether-insoluble Fractions of Extracts of Rhubarb Petioles

DURING the past four years efforts have been made in this laboratory to evolve methods suitable for the purification of coleoptile growth promoters known to be present in water-soluble, ether-insoluble fractions of plant extracts In previous work[1] ethanolic extracts from which ether-soluble compounds had been removed were chromatographed directly In the present work large quantities of elongating rhubarb petioles were extracted, and it was necessary to purify these 'final ethanol extracts' further Two of the most promising procedures are described here

(1) *Alumina column purification* Very clean preparations are obtained when the 'final ethanol extract' is run through an alumina column It has not been possible to specify the exact conditions of experiment necessary to give an active extract Fig 1 shows some of the properties of an active preparation The general trend of the results has been confirmed in independent experiments, and is similar in many ways to other work on so-called 'interconvertible' auxins[1,2] Four identical chromatograms were prepared , one was assayed directly (*a*), and selected zones on the others were eluted in ethanol and then re-chromatographed (*b*–*e*) Since the activity is highly labile, distilled water was chosen as the chromatographic solvent, because of its neutrality and speed of running Relative to the original chromatogram, the eluates show greater activity, except in the case of the R_F 0 55–0 7 eluate (*c*), which lies between two sources of promoter(s) on the original strip Elution without re-chromatography does not give a comparable release of activity. Thus, when segments of a chromatogram are placed in separate vials and treated with ethanol for 2 hr (as in the standard elution procedure), then the ethanol evaporated off and bioassay medium added, there is no enhancement (*f*) If the whole chromatogram is eluted and re-chromatographed, there is enhancement (*e*) It may be suggested that losses during manipulation lead to an increase in promotion by diluting the original quantities to less than supra-optimal concentrations Alternatively, release of promoter(s) from precursor(s) may be involved.

(2) *Tert -butanol chromatography* Active preparations quite distinct from those described above can be obtained consistently by applying the 'final ethanol extract' to Whatman No 3 paper as a strip and chromatographing at 30°–35° C using *tert* -butanol as solvent. Much anthocyanin and other material is retained in the R_F 0–0 5 region, while some stimulators are washed farther down the paper (Fig 2*a*).

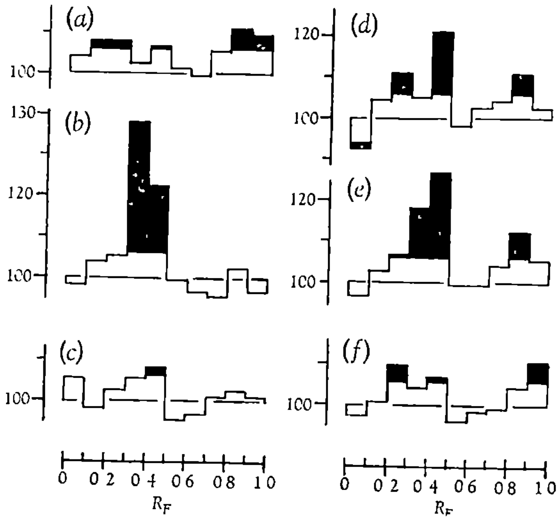

Fig 1 *Avena* coleoptile straight-growth activity on chromatograms (method as in ref 1) Vertical scales represent section length as percentage of controls Responses outside fiducial limits of controls are blacked in Each chromatogram represents 10 gm fresh weight of petioles *a*, Assayed directly, *b*, *c*, *d* and *e*, assayed after zones 0 2–0 5, 0 55–0 7, 0 8–1 0 and 0–1 0 respectively had been eluted and re-chromatographed, *f*, see text All assays were carried out on the same occasion

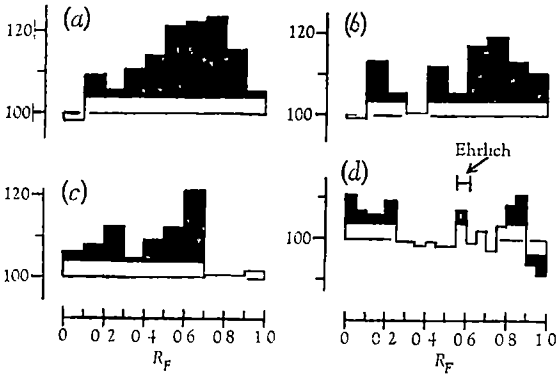

Fig 2 *a*, *Tert* -butanol chromatogram of final ethanol extract, *b*, *c* and *d*, are re-chromatographed eluates using distilled water, *b*, isobutanol/methanol/water, 80 5 15, *c*, and isopropanol/0 880 ammonia/water, 8 1 1, *d*, as solvents *d* represents 16 gm, the others 10 gm fresh weight of petioles

This active zone can then be eluted and re-chromatographed with other solvents on Whatman No 1 paper Histograms of activity for three solvents that have been commonly used in investigations of ether-insoluble auxins[1,2] are shown in Fig 2*b*, *c* and *d*.

Identification of two of the spots resolved by isopropanol / ammonia / water was achieved using an extract of 8 kgm of petioles.

Spot (i) R_F 0–0 25. Elementary analysis, titrations, ion-exchange chromatography, and infra-red spectrum identified the material as the half ammonium salt of malic acid. Malic acid itself is not a growth stimulator in the assay system used (the medium contains citrate as part of the buffer solution), but the half ammonium salt, and ammonium (as phosphate) are slightly active This particular spot may therefore be an artefact of ammoniacal chromatography

Spot (ii) This was located by its Ehrlich reaction (Fig. 2*d*) rather than its weak growth activity It was eluted and shown to co-chromatograph with 2·7 × 10^{-3} μc aliquots of carbon-14 labelled tryptophan in a series of 21 different one-dimensional solvent systems

When this *tert* -butanol method of purification was used checks were made to show that the 'alumina auxins' were absent There are other indications that the two methods yield quite different substances For example, the '*tert* -butanol' group do not show R_F shifts, or release of growth activity when zones of chromatograms run using water as solvent are eluted and re-chromatographed Again, they are stable, and do not pass through an alumina column

PHYSIOLOGY

Peroxide-like Substance in Alarmed Mice

WHILE studying the production of an oxidizing agent which could be extracted with butanol (hereinafter called 'apparent peroxide') in X-irradiated mice, we found that some was produced without irradiation, merely by transferring the mouse somewhat roughly to the small irradiation chamber (Work on irradiated and dummy-irradiated mice will be submitted to the *International Journal of Radiation Biology*) As this phenomenon may be of physiological interest we have made a few further observations on it

The apparent peroxide was estimated with anaerobic leuco brilliant cresyl blue, approximately as previously described[1]. The temporal sequence of experimental and control mice was randomized to eliminate secular effects Table 1 shows that merely lifting mice by their tails with rubber gloves (to avoid possible transfer of peroxide from the hands) produced a statistically significant difference in peroxide between six experimental animals and six controls. Table 2 shows the larger effect of lifting by the scruff of the neck with polythene-covered forceps. Fig 1 shows that the increase was maximal within 1 min after lifting with forceps and that it fell to half the maximum in about 97 min

Table 1

Micromoles of peroxide/gm of mouse

	Not handled	Lifted by tail
	0 13	0 24
	0 19	0 28
	0 23	0 25
	0 24	0 27
	0 28	0 25
	0 20	0 27
Mean	0 21	0 26

The difference in means would occur by chance about 1 in 50 times and is therefore significant

Table 2

Micromoles of peroxide/gm of mouse

	Not handled	Lifted by scruff of neck with forceps
	0 23	0 35
	0 13	0 39
	0 27	0 33
	0 25	0 36
	0 24	0 37
Mean	0 22	0 36

The difference in means would occur by chance less than 1 in 1,000 times and is therefore significant

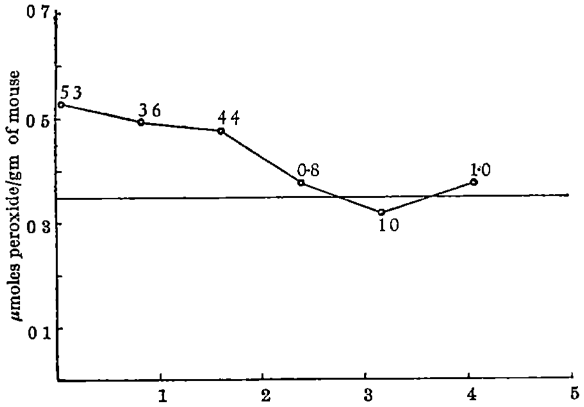

Fig 1 Peroxide in alarmed mice as a function of time The figure beside the points are a value of the statistic *t* between each experimental group (wavy line) and the untreated group (horizontal straight line) The 5 per cent and 1 per cent levels of *t* are 2 18 and 3 05 respectively The biological half-life of the peroxide is estimated by interpolation to be 97 min Each point represents a mean of seven mice The times were randomized in a Latin square

The identity of the peroxide-like substance or substances concerned is unknown. Adrenochrome, a possible though doubtful metabolite of adrenaline, has the necessary chemical properties ; but Table 3 shows no mean difference between mice injected intraperitoneally with adrenaline and with saline, though both increase the apparent peroxide presumably through alarm from the injection

Table 3

Micromoles of peroxide/gm of mouse

	Injected with saline	Injected with adrenaline
	0 29	0 38
	0 29	0 34
	0 36	0 25
	0 33	0 22
	0 38	0 44
Mean	0 33	0 33

With adrenocorticotrophic hormone (Table 4) only a small mean difference above saline, statistically insignificant with groups of five mice, was found.

Table 4

Micromoles of peroxide/gm. of mouse

	Injected with saline	Injected with adrenocorticotrophic hormone (0 05 unit/mouse)
	0 25	0 38
	0 30	0 33
	0 25	0 24
	0 35	0 37
	0 24	0 31
Mean	0 28	0 33

The difference in means would occur by chance about 1 in 5 times and is not significant

It is therefore possible that the present phenomenon depends on some hitherto unknown component of the total response to alarm, involving perhaps autoxidation of unsaturated substances such as linoleic acid to form hydroperoxides

Evidence for Independence of Voltage of the Membrane Conductance of Rabbit Ventricular Fibres

AT the present time the available evidence indicates that the prolonged repolarization phase of the cardiac action potential is associated with a drop in the membrane conductance to potassium ions (g_K) which occurs during, or shortly after, the upstroke of the action potential and persists for the major part of the repolarization phase Noble[1] has put forward a mathematical model which reproduces Purkinje-like action potentials In this model, g_K is an instantaneous function of the membrane potential and falls when the membrane is depolarized

We have previously shown[2,3] that the displacement of membrane potential produced by hyperpolarizing current applied during the repolarization phase of rabbit ventricular action potentials bears a linear relationship to the magnitude of the applied current This finding suggests that the ionic conductance of the membrane does not change with the value of the membrane potential, as it should were it to conform with Noble's model

The following experiment further affirms the independence of voltage of the ionic conductance of membrane action potentials of rabbit ventricular fibres The tissue was stimulated at a rate of 3 4 sec^{-1} Double-barrelled microelectrodes were used together with a current clamp and associated apparatus previously described[4] Hyperpolarizing current was passed through the cell membrane via one barrel of the electrode, the other barrel recording the resulting potential change The current was started approximately 50 msec before the upstroke of every fourth propagated action potential and terminated during the early half of the repolarization phase. A typical result is shown in Fig 1 A fairly accurate estimate of the hyperpolarization produced at any time is afforded by superimposing the crests of the two action potentials and measuring the potential displacement of the normal action potential and that occurring during flow of current[4].

If the ionic conductances were dependent on voltage then, during the hyperpolarization, they would assume new values, so that, at the break of the current pulse, the subsequent time course of potential

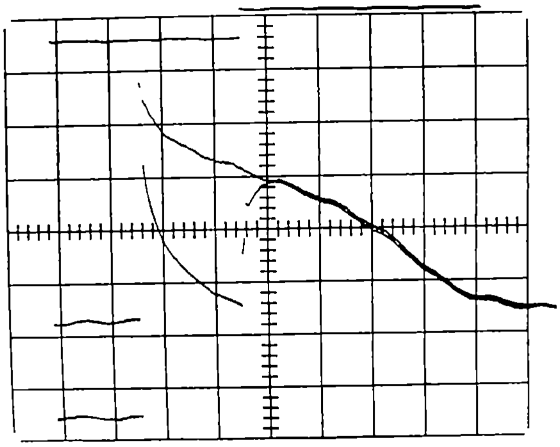

Fig 1 Top trace current (hyperpolarizing), calibration, 0 25 μamp per large division Lower trace upper of the two, an action potential recorded before the application of current, lower trace action potential recorded during current flow The current pulse was started 50 msec before the upstroke of the action potential and terminated, as shown, during the repolarization phase Calibration 25 mV and 20 msec per large division

should differ from that of a normal action potential. The outcome of the experiment is clearly shown in Fig. 1, where the voltage displacement is close to 50 mV. just prior to the break of the current. After the break of the current the membrane potential returns within 10 msec to a time-course identical to that of the preceding normal action potential. During this 10-msec. interval, a brief voltage spike may occur. Its amplitude depends on the value of the current and the time of break of the current. We believe that this spike is the result of a localized, non-propagated increase in sodium conductance subsequent to 'reactivation' produced by the preceding hyperpolarization. However, even in these instances, the membrane potential returns to its normal time-course after the spike.

These facts are in accord with the hypothesis that a sodium-carrying mechanism dependent on voltage exists in rabbit ventricular fibres, but that the subsequent decrease in g_K, which normally follows the activation of such a sodium-carrying mechanism, is independent of voltage.

Effect of L-Glutamic Acid on the Weight of Embryonic Chick Tibiotarsi cultivated *in vitro*

IN a previous communication[1] the dose-response line relating the final length of embryonic chick tibiotarsi cultivated *in vitro* and the concentration of L-glutamine in the medium was described. Furthermore, it was shown that the presence of 25 mgm per 100 ml. L-glutamic acid in the medium had no effect on the position of the L-glutamine dose-response line. From this result it was argued that L-glutamic acid does not act as a precursor for L-glutamine in this system. The purpose of the present communication is to present additional results on the wet and dry weights of the same bones. These results were not included in the first communication since their discussion was irrelevant to the point at issue, and could have created confusion.

The experiment was a 2×3 factorial design: 1, 5 and 25 mgm per ml. L-glutamine and 0 and 25 mgm per 100 ml. L-glutamic acid were incorporated in all six treatment combinations in the chemically defined medium *BGJb*[2]. The experimental error was reduced by utilizing a balanced incomplete block design for comparing six treatments in blocks of two, thereby exploiting the uniformity of the pair of bones from each embryo. The bones were cultivated, using the floating lens paper technique, at 37° C. for six days in an atmosphere of humidified 5 per cent carbon dioxide in air. The medium was renewed every second day. At the end of the experiment the wet weight and dry weight of each bone were determined on a Cahn electric microbalance using the techniques described elsewhere[3]. The analyses of variance were done after all the data were converted to logarithms.

Table 1. ADJUSTED MEAN LOG WET WEIGHTS (MGM.) AND MEAN LOG DRY WEIGHTS (μGM.) OF SEVEN-DAY OLD EMBRYONIC CHICK TIBIOTARSI AFTER CULTIVATION FOR 6 DAYS ON MEDIUM *BGJb*, IN THE PRESENCE OF VARIOUS COMBINATIONS OF L-GLUTAMINE AND L-GLUTAMIC ACID. EACH MEAN IS BASED ON FIVE OBSERVATIONS

	L-Glutamine (mgm. per cent)					
L-Glutamic acid (mgm. per cent)	log wet weight 1	5	25	log dry weight 1	5	25
0	0·032	0·088	0·305	1·932	1·979	2·177
25	0·102	0·230	0·403	2·062	2·104	2·259

Analyses of variance
(Calculated using the methods of Kramer and Bradley, ref. 4)

Source of variation	D.F.	Mean squares log wet weight	Mean squares log dry weight
Between embryos (unadj.)	14	0·0175	0·0164
Between treatments (adj.)	(5)		
L-glutamic acid	1	0·0481*	0·0566*
L-glutamine			
Linear	1	0·2480‡	0·1463†
Quadratic	1	0·0105	0·0176
Interaction	2	0·0020	0·0011
Intrablock error	10	0·0055	0·0093

*$0·05 > P > 0·01$; †$P < 0·001$; ‡$0·01 > P > 0·001$.

The adjusted means are shown in Table 1, together with the analyses of variance. As with the results on length[1] there are highly significant linear regressions of log wet weight and log dry weight on the logarithm of the concentration of L-glutamine in the medium. The mean squares for L-glutamic acid are both significant at the $P = 0·05$ level. Inspection of the adjusted means shows that the presence of L-glutamic acid has increased the wet and dry weights of the bones at all levels of L-glutamine. Since the interaction mean square is not significant in either analysis of variance we may assume that the L-glutamine dose-response lines for both responses, in the presence and absence of L-glutamic acid, are parallel. The vertical distance between these lines is an estimate of the logarithm of the ratio between the weight of a bone in the presence of L-glutamic acid and the weight of a bone in the absence of L-glutamic acid. These ratios, and their fiducial limits of error ($P = 0·05$), have been calculated from the data in Table 1, and are found to be: wet weight, 1·27 (1·06–1·52), dry weight, 1·30 (1·03–1·64). The corresponding ratio for the data on length is 1·03 (0·90–1·18). The difference between the results for length and wet and dry weights is therefore considerable. Further statistical analysis showed that L-glutamic acid and L-glutamine had no significant effects on the dry weight/wet weight ratios of the rudiments.

The results demonstrate that the weights of embryonic chick tibiotarsi are increased by supplementing medium *BGJb* with L-glutamic acid. The increase is 27 per cent in wet weight and 30 per cent in dry weight. Medium *BGJb* contains twelve essential amino-acids and L-glutamine[5]. Although L-glutamic acid can be synthesized by these rudiments from glucose[6] the amount produced in this medium appears to be insufficient to produce a maximal response. In earlier work on the effect of amino-acid deficiencies on the growth in wet weight of chick tibiotarsi[7] it was shown that L-glutamic acid could be omitted from medium 858, which contains 20 essential and non-essential amino-acids, without affecting the response in wet weight. It seems likely, therefore, that when L-glutamic acid is omitted from medium 858, some other non-essential amino-acid can substitute for it. This could be either by its conversion to L-glutamic acid, or through its having an identical physiological activity.

We should not be dismayed that the results on length and the weights of the bones do not agree, since there is increasing evidence[8] that the elongation of the chick tibiotarsus is caused largely by hypertrophy of the diaphyseal chondrocytes, and that mitosis and the secretion of matrix by the chondrocytes play only a minor part. Thus L-glutamic acid probably produces its effects on the weights of the rudiments by stimulating mitosis and/or the secretion of matrix, and has little connexion with the mechanism of hypertrophy. The activity contrasts sharply with the effect of L-glutamine, which seems to be important for elongation as well as growth in weight

Work on the nutritional requirements of whole animals has shown that L-glutamic acid is not required for adult rats, men, and roosters , it is required, however, for the optimum growth of young chicks, rats and mice, and for egg production by hens[9]. In all these investigations the basal diet contained a minimal number of amino-acids The results described in this communication on the nutrition of an organ growing *in vitro*, on a chemically defined medium containing a minimal number of amino-acids, are remarkably similar to the results on whole animals.

Effects of Intraventricularly Injected Anti-N. Caudatus Antibody on the Electrical Activity of the Cat Brain

It is well known that anti-tissue antibodies, when injected into an animal of the donor species, may exhibit the selective affinity for the homologous organ and produce certain modifications in its morphological and functional state[1] The damaging effects of anti-tissue antibodies have been demonstrated in different organs[2] However, no information could be found in the literature available concerning the physiopathological events associated with an *in vivo* collision between anti-brain antibodies and the corresponding nervous tissue Bearing in mind the high complexity of morphological and functional organization of the brain, a series of immuno-electrophysiological experiments has been undertaken to investigate the possible differential reactivity of various cerebral structures when exposed to the action of different brain region anti-sera The present communication, as a part of these investigations, is a preliminary report concerning only some of the effects of intraventricularly administered anti-n. caudatus antibody on the electrical activity of various parts of the cat brain

Cats operated under 'Nembutal' anæsthesia were used. Surface and depth, 'Teflon'-insulated silver and stainless steel electrodes (0 005–0 01 in in diameter), respectively, were implanted into various regions of the brain (frontal cortex, frontal white matter, n caudatus, hippocampus, hypothalamus, thalamus and brain stem reticular formation). Needle electrodes for the interior of the brain were introduced by means of a Horsley-Clarke stereotaxic instrument All electrodes were implanted into the left cerebral hemisphere, while the cannula was inserted into the right lateral ventricle, according to the method of Feldberg and Sherwood[3] Electrical activity was recorded throughout the experiment using a 12-channel Reega-Alvar electroencephalograph Details regarding recording and stimulation technique have been published elsewhere[4]

The cat n caudatus was carefully dissected, homogenized, mixed with Freund adjuvant and injected subcutaneously into rabbits (1 0 gm of fresh tissue per kgm. body-weight) The γ-globulin from the immune rabbit sera was separated by the method of Basset *et al* [5] Immune rabbit γ-globulin was investigated by diffusion-gel[6] and complement fixation reaction[7], in which the saline extract of n. caudatus tissue was used as antigen The reaction between n caudatus antigen and the corresponding immune rabbit γ-globulin revealed 2–3 precipitin lines in the agar and a titre of 1/128–1/256 in the complement fixation test Normal rabbit γ-globulin, taken prior to the immunization, did not show any serological activity with antigen prepared from the n caudatus tissue

The cats were divided into three groups the first (experimental group) was treated with immune rabbit γ-globulin, the second (control group) received normal rabbit γ-globulin, and animals from the third (control group) were injected with physiological solution in order to evaluate the possible influence of volume of injected fluid Two to three injections of 0 3 ml daily, with an interval of 60 min between the injections, were administered on four successive days Total protein content of immune rabbit γ-globulin injected into an animal of the first group was 46 08 mgm , while that of normal γ-globulin administered to an animal of the second group amounted to 60 24 mgm

Some of the results are illustrated in Fig 1. In both control groups no essential change in electrical activity of various cerebral structures investigated could be noticed Records made in the course of normal γ-globulin application, as well as the records taken at intervals within the period of one month following the last injection, were found to be fairly comparable with the activity recorded prior to the γ-globulin administration (Fig 1*A*) However, in the experimental group of animals, intraventricular application of anti-n caudatus γ-globulin was followed by pronounced modification in electrical activity The evolution of electrographic disturbances seemed to pass through three consecutive stages The first stage was characterized by the appearance of spikes and high-voltage sharp waves localized in the n caudatus. These transient irritative abnormalities become apparent on the third day of antibody administration, and disappeared two to three days afterwards The second, also transient stage was characterized by slight general accentuation of background activity and by sporadic appearance of diffuse abnormalities consisting of bursts of 4–6/sec high-voltage waves, in all leads. Such activity outlasted the disappearance of spikes and sharp waves in n caudatus for several days The

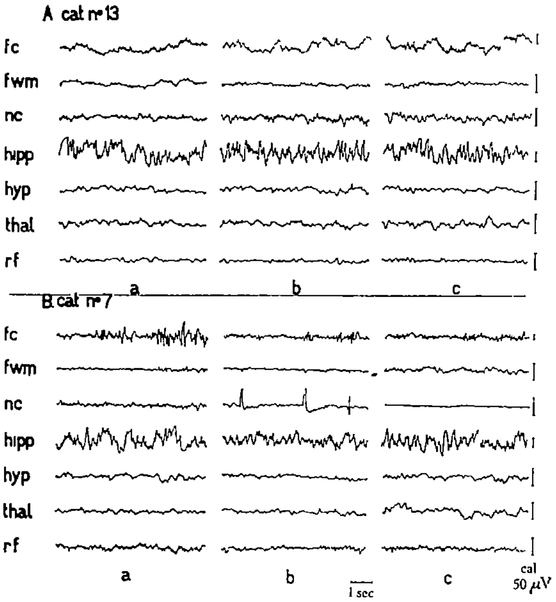

Fig 1 *A*, Records made (*a*) before administration, (*b*) following the third day of injecting, and (*c*) eight days after the last injection of normal rabbit γ-globulin *B*, Records taken (*a*) prior to antibody application, (*b*) after the third day of injecting and (*c*) seven days following the last intraventricular injection of anti n caudatus γ-globulin *fc*, frontal cortex, *fwm*, frontal white matter, *nc* n caudatus, *hip*, hippocampus, *hyp*, hypothalamus, *thal*, thalamus, *rf*, brain stem reticular formation, for explanation, see text

third stage was characterized by gradual slowing down, progressive decrease in the amplitude and almost complete disappearance of spontaneous electrical activity of the caudate nucleus within a month after antibody administration (Fig 1*B*). Such an evolution of electrographic abnormalities was reflected in modification of potentials in n caudatus evoked by acoustic stimuli, as well as in the change of activity propagated to n caudatus during seizures induced by electrical stimulation of the hippocampus It should be emphasized that no change in electrical activity of the caudate nucleus could be observed in animals treated with anti-hippocampus antibody (unpublished experiments).

In a previous paper[7] it was found that lipids from various regions of cat brain lack individual specificity but are all highly organ-specific. That is why, in the present experiments, the saline extract of n caudatus containing mainly protein components has been used as antigen in preparing the corresponding anti-serum N. caudatus was chosen because it forms the wall of the lateral ventricle and could be, therefore, easily attacked by the intraventricular route and thus brought into prolonged contact with antibody injected into the cerebrospinal fluid This, of course, could not be assured adequately if the antibody were administered by a systemic route[8] Diffuse electrographic abnormalities reported here were also observed following intraventricular administration of some other anti-brain region sera, such as anti-hippocampus, and should be, therefore, considered as nonspecific manifestations However, the initial irritative phenomona, followed by a progressive decrease in electrical activity, strictly confined to n caudatus, strongly suggest that anti-n caudatus antibody has definite affinity towards the homologous nervous tissue.

Effect of Colchicine on Rat Liver Xanthine Oxidase

Colchicine has been shown to inhibit deoxyribonuclease and de-phosphorylation and de-amination of deoxyribonucleotides[1]. The beneficial effect of colchicine in gout is possibly due to the effect of this drug on purine metabolism, since human serum nucleotidase and guinea pig liver xanthine dehydrogenase are inhibited by the alkaloid—the last-named only when given in large doses[2]. The purpose of the present communication is to investigate the effect of colchicine on rat liver xanthine oxidase, and on the purified enzyme

Male Wistar white rats on a well-balanced diet were used throughout this work Liver xanthine oxidase was determined from the oxygen uptake in a conventional Warburg apparatus at 37° C, using hypoxanthine as a substrate and air as the gas phase[3] The xanthine dehydrogenase activity was measured using the anaerobic reduction of the colourless dye triphenyltetrazolium chloride in a Thunberg vacuum tube as suggested by Villela[4] Pyrophosphate buffer (0 015 *M*), *p*H 8 6, was used in both determinations The results were expressed in mm ^{3} oxygen/gm dry weight/60 min for xanthine oxidase and in μgm formazan/gm dry weight/30 min for xanthine dehydrogenase activity

Colchicine (0 1 mgm /100 gm. body-weight) was administered by intraperitoneal injection of an alcoholic solution (6 8 per cent) containing 20 mgm

Table 1 Liver Xanthine Oxidase and Xanthine Dehydrogenase of Rats injected with Colchicine and with Thiocolchicoside

Conditions	No. of rats		Xanthine oxidase* (mm ^{3} O_2/gm dry weight in 60 min)	Xanthine dehydrogenase* (μgm formazan/gm dry weight in 30 min)

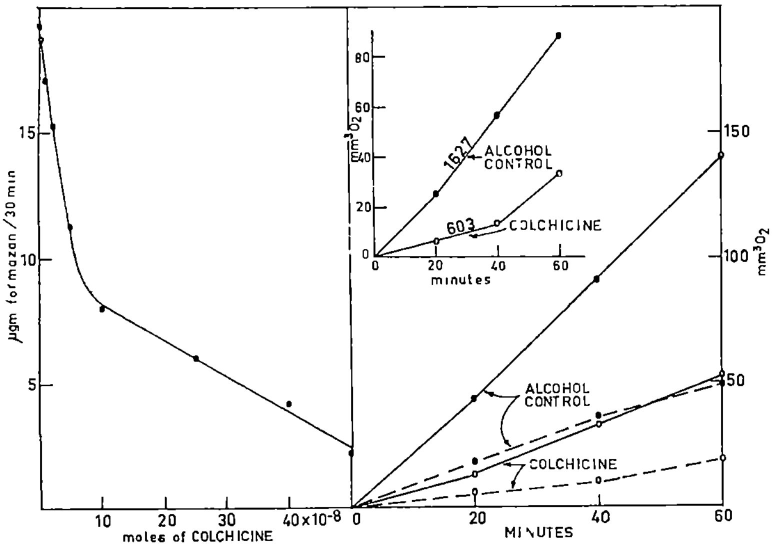

Fig 1. Rat liver xanthine oxidase and xanthine dehydrogenase inhibition by colchicine. Left, *in vitro* inhibition of purified xanthine dehydrogenase activity. Right, *in vivo* inhibition of liver xanthine oxidase activity. The graph in the upper part represents values of net oxygen uptake in mm³ oxygen/gm dry weight/60 min

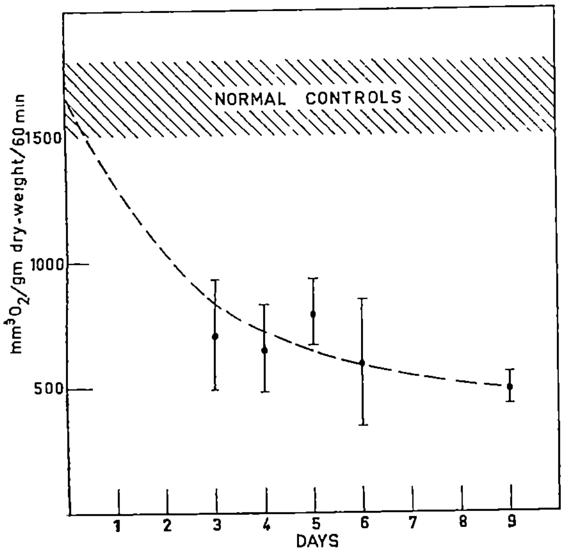

Fig 2. Rat liver xanthine oxidase inhibition by colchicine in diet. Dotted line of the curve represents the decrease of activity. Abscissa: Time in days in which the rats were fed with colchicine

of colchicine per 100 ml. Blanks were performed by injecting a 6·8 per cent alcoholic solution. Colchicine was administered orally *ad libitum* by adding colchicine (Houdé) to the diet (5 mgm /100 gm).

For *in vitro* experiments purified liver xanthine oxidase was prepared by solubilization of the enzyme with butanol[5] after the digestion of rat liver homogenate (in 0·2 *M* Na_2HPO_4) with crude trypsin at *p*H 7·3. After precipitation with ammonium sulphate between 30 and 60 per cent saturation, the enzyme was adsorbed in $Ca_3(PO_4)_2$ and eluted with 0·1 *M* pyrophosphate buffer, *p*H 8·6.

Experiments *in vitro* with 5×10^{-7} mole of colchicine did not show any statistically significant difference in the activities of xanthine oxidase or xanthine dehydrogenase when rat liver homogenate in pyrophosphate buffer was used. However, with purified enzyme, an inhibitory effect was obtained even with 10^{-9} mole of colchicine (Fig 1, left).

Values for normal rats and controls injected with alcohol as well as rats fed with colchicine are reported in Table 1. A statistically significant inhibitory effect was observed with colchicine for the liver enzyme activity (for xanthine oxidase, $t = 4·50$, $P < 1$ per cent, for xanthine dehydrogenase, $t = 7·75$, $P < 1$ per cent) (Fig 1, right). When the drug was administered orally the inhibition was noted in the first days (Fig 2).

Thio-colchicoside ($C_{27}H_{33}O_{10}NS$), a sulphur-containing analogue of colchicine without antimitotic activity, was used in some other preliminary experiments but appeared to be without any inhibitory effect (Table 1).

The results reported indicated that colchicine has an inhibitory effect on liver xanthine oxidase and xanthine dehydrogenase activities when given to rats orally or in the peritoneum. Although the liver homogenate protects this effect *in vitro*, the purified enzyme is inhibited with small doses of the drug.

Effect of Hydrocortisone on Uptake of Iron-59 in Incubated Rat Red Cells *in vitro*

Hydrocortisone added to blood containing reticulocytes in a suitable substrate did not alter the rate of synthesis of hæmoglobin and no evidence was obtained that it influenced the rate of ripening of reticulocytes. This applied to various dosage-levels *in vitro* and to plasma obtained from animals which had been injected with large doses of hydrocortisone. It was shown, however, that preliminary incubation of reticulocytes with hydrocortisone before the addition of iron-59 reduces the amount of iron-59 which enters the reticulocytes.

Reticulocytosis was induced in laboratory rats by intraperitoneal injection of phenylhydrazine hydrochloride. Five days later, blood was removed by cardiac puncture and collected in heparin. Iron-59 uptake was measured by incubating 1-ml portions of blood with hydrocortisone sodium succinate (supplied by courtesy of the Upjohn Chemical Co.) in physiological saline. About 0·4 µc of iron-59 as ferric chloride was added at various times, the cells incubated for a further 2 hr., washed 10 times with physiological saline and assayed with an EKCO scintillation counter.

In all instances the uptake of iron-59 in the presence of hydrocortisone was compared with the uptake in the presence of sodium succinate, because it has been shown that preliminary incubation itself reduces uptake[1]. It was found that the amount of iron-59 entering the reticulocytes was not altered by preliminary incubation for up to 5 hr in the presence of hydrocortisone at concentrations between 0·0083 and 0·500 mgm./ml. of blood. However, an increase in the concentration to 1·0, 1·5 and 2·0 mgm./ml. resulted in a reduction of uptake of iron-59 which was proportional to the concentration of hydrocortisone.

This effect of hydrocortisone is shown in the following experiment in which reticulocytes were incubated for different times with varying concentrations of hydrocortisone. Blood samples of 1 ml. were incubated for 2 and 5 hr. in the presence of 0·5 or 1·0 mgm. hydrocortisone. Iron-59 was added and the uptake observed at 2, 4 and 6 hr. Hydrocortisone did not influence the amount of iron-59 in the cells with only 2 hr. incubation. It was also without effect, compared with the controls, when the cells were incubated with 0·5 mgm./ml. for 5 hr. There was, however, a marked decrease in the total uptake of iron-59 after 5 hr. incubation with 1·0 mgm. hydrocortisone and this effect was still further increased when the cells were suspended in saline instead of their own plasma.

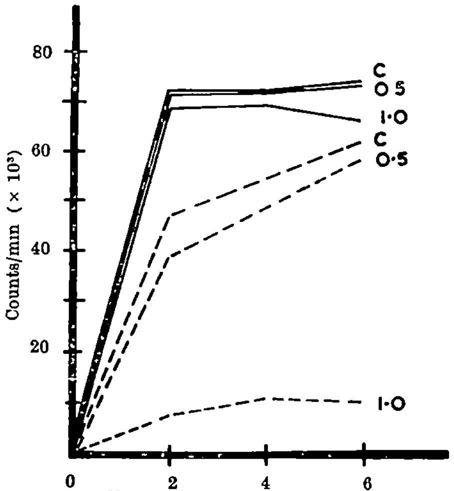

Fig. 1. Uptake of iron-59 in pre-incubated rat reticulocytes. ——, 2 hr. pre-incubation; ----, 5 hr. pre-incubation

Warburg experiments on 2-ml. blood samples showed a slight decrease in oxidative respiration in the presence of hydrocortisone sodium succinate, but a similar decrease was found in sodium succinate. Incubation with 1·0 mgm./ml. hydrocortisone resulted in a marked increase in the rate of outward movement of potassium, but incubation with 0·5 mgm./ml. hydrocortisone did not produce a significant increase.

Hydrocortisone in high concentration thus increases the pre-incubation effect already observed by Clark and Walsh[1], although its action on the reticulocytes is slow. It also causes a change in certain permeability properties but no change in oxidative respiration. It is not known whether hydrocortisone operates by means of the same mechanism as pre-incubation, or whether some other mechanism is involved. It may produce its effect (*a*) by causing the reticulocytes to mature more rapidly, thus decreasing the iron-59 requirement, or (*b*) by altering some components of the reticulocytes so that less iron can be accepted. A reduction in oxidative respiration would have been expected if the effect were an increase in the rate of maturation of reticulocytes, because such maturation is characterized by loss of the oxidative pathway. On the other hand, there is evidence that hydrocortisone affects the permeability of reticulocytes.

Reticulocytes therefore differed from rat liver cells[2] in their reaction to hydrocortisone because (*a*) hydrocortisone must be used in high concentration before any effect is observed with reticulocytes, and (*b*) oxidative respiration of reticulocytes is not affected by hydrocortisone even in high concentrations. These differences are probably related to differences in metabolism and structure of the two types of cell.

Action of Methyl Hydroxybenzoate on Nervous Conduction

METHYL hydroxybenzoate and its sodium derivative are recommended by the B.P.C. and by Martindale[1] as preservatives for creams, emulsions, lotions and ophthalmic solutions, and they are used to preserve local anæsthetics. During an investigation of the action of phenol on nerve fibres[2,3], we examined the action of methyl hydroxybenzoate and its sodium derivative on conduction in fibres of the spinal roots of the cat, and also on the vagus and sympathetic nerves.

These substances, dissolved in Krebs's solution to form 0·1 per cent and 0·2 per cent solution, when applied directly to the spinal roots or to the vagus and sympathetic bundle in the neck, block conduction in nerve fibres of all sizes, myelinated and unmyelinated. The effect was typical of a local anæsthetic in that small fibres were blocked before large and that the conduction block was reversible. The blocking effect of a 0·1 per cent solution of methyl hydroxybenzoate was found to be similar to that of a 0·05 per cent solution of procaine.

The substances are recommended as preservatives, as, according to Martindale, they are "inert and non-toxic". The results mentioned above were obtained with the weakest solutions recommended by the B.P.C., the concentrations advocated being 0·1 and 0·2 per cent methyl hydroxybenzoate and 0·1–0·3 per cent of the sodium derivative.

The fact that in acute experiments conduction returned in fibres which had been blocked, following removal of the substance and washing the root or nerve bundle, cannot be taken to mean that no subsequent degeneration of the affected nerve fibres takes place. Exactly this situation occurs with phenol in non-aqueous solution. Although electrophysiological techniques have shown recovery of conduction in fibres which have been blocked by phenol, there is histological evidence of subsequent massive degeneration among these fibres[4]. If methyl hydroxybenzoate causes similar effects, it is possible that the degeneration of a proportion of nerve fibres following the injection of local anæsthetics in various painful states may account for the prolonged or permanent relief of the pain that sometimes occurs Whether this is the explanation of the prolonged therapeutic effect of local anæsthetics or not, it remains important to note that such recommended preservatives are not inert and that their presence should be taken into account both in experimental and in therapeutic situations

HÆMATOLOGY

Alkali-resistant Hæmoglobins in Prosimian Primates

PROSIMIAN Primates are a group of animals which share characteristics of behaviour, anatomy, biochemistry, cytogenetics, and physiology with the monkeys on one hand and the more primitive Insectivora on the other[1] We have been examining the hæmoglobins of a number of these animals One of our most interesting discoveries is the relatively high level of alkali-resistant hæmoglobin found in these animals

Blood samples were taken from the femoral veins of anæsthetized or tranquillized animals. Hæmolysates were prepared as described by either Jonxis and Huisman[2] or Singer *et al* [3]. The alkali-denaturation tests were carried out by the method of Singer *et al* [3] All samples were read in a Coleman Junior spectrophotometer at 540 mμ Fresh and stored samples gave essentially identical results

The results given in Table 1 include those from tests on individual adult and juvenile animals from a variety of genera of Primates These results are of some comparative interest, since we have found no significant amounts of alkali-resistant pigments in adult animals in the Anthropoidea There is a difference in average amount of alkali-resistant pigment among the three major groups of Prosimians tested The Lemuriformes appear to have the highest average levels, 41–75 per cent, the Lorisiformes have levels between 8 4 and 52 per cent, and the single Tupaiiformes sample showed 9 per cent alkali-resistant hæmoglobin The age of the animals apparently is not related to the amount of denatured pigment, since several in each group, except *Tupaia glis*, were infant or juvenile animals This is in marked contrast to the higher Primates which have been examined Singer *et al* [3] found, in new-born human beings, a high level of alkali-resistant hæmoglobin (80 per cent), the level afterwards fell to the negligible value of 1 7 per cent at the age of 36 months Similar values have been found in *Macaca mulatta*[4]

Electrophoresis on starch-gels of hæmoglobin from the animals studied here, with Poulik's discontinuous buffer system[5], demonstrated at least two components in all the Lorisiformes and in most of the Lemuriformes One of these components may correspond to the alkali-resistant fraction we found A detailed account of the hæmoglobins of these Prosimians is in preparation

Ateles spp	2	0 6	0 5–0 7
Pan troglodytes	1	0 2	

* Species identification in doubt The animals appear to be of the *G crassicaudatus* group, however, some authorities have called them *G senegalensis zanzibaricus*

One elephant shrew (*Elephantulus rufescens*) of the order Insectivora was examined According to Polyak[6] *Tupaia* is closely related to this species. A level of about 0 4 per cent alkali-resistant hæmoglobin, which is negligible, was found in our sample from an old animal

The question of the nature of this alkali-resistant hæmoglobin in the Prosimians is raised There is little doubt that in higher Primates, including man, this hæmoglobin is the principal fœtal pigment. The term fœtal would be misleading, if not incorrect, when applied to the alkali-resistant fraction of Prosimian hæmoglobin. A possibility is that this hæmoglobin in the Anthropoidea was originally a major component of the respiratory pigment, as in the Prosimians, but gradually became confined to a shorter period in the animal's life, until, in the highest Primates, it is present only in the fœtus and during the first few months of life This hypothesis requires an investigation into the physiological function of the alkali-resistant pigment in Prosimians

Our work was supported by Research Grant 6053 of the United States Public Health Service, Research Grant 12331 of the National Science Foundation, and the research fund of the Department of Anthropology, Yale University It is with pleasure that we acknowledge the assistance and encouragement of colleagues in various countries who helped us obtain the live animals used in this work

PATHOLOGY

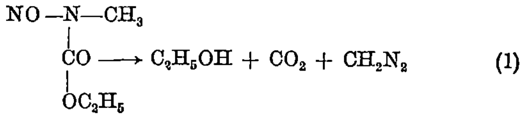
Interaction of the Carcinogenic *N*-Methyl-Nitrosourethane with Sulphydryl Groups

In a preliminary communication I recently reported the production of lung adenoma in mice and squamous lung carcinoma in a rat, which was exposed to gaseous diazomethane. Among other rats given *N*-methyl-*N*-nitrosourethane (NMU) by stomach tube, a carcinoma of the stomach developed after a single dose of this compound[1].

Since this communication was published, more stomach tumours have been observed in the rats given NMU by stomach tube[2]. Stomach tumours have also been reported in rats given NMU in drinking water continuously until death[3]. Moreover, when NMU was administered to adult rats by a short mouse-stomach tube, the animals developed œsophageal squamous carcinoma[2]. Subcutaneous injections into mice gave rise to local sarcomata. It is evident that NMU acts at the site of application and that it is able to produce tumours in various tissues. This would qualify it to be considered a 'local' carcinogen.

However, the evidence described here indicates that the effective entity is not NMU but diazomethane, which is formed when NMU interacts with tissues. In 1895 von Pechmann[4] suggested that the toxic effects of NMU, which he observed on himself, might be due to diazomethane, formed from NMU in contact with tissues.

That this is really the case was qualitatively confirmed in the following way. NMU was added to tissue homogenates at 37° C. and the mixture was covered with a layer of ethyl ether. Rapid evolution of gas occurred; the gas bubbled through the layer of ether. This indicated that the gas is not soluble in ether, hence it is not diazomethane. Evidently, the diazomethane formed according to reaction (1) reacts immediately with tissue constituents, with evolution of nitrogen according to reaction (2).



$$\begin{array}{l} NO-N-CH_3 \\ \quad\;\; | \\ \quad\;\; CO \longrightarrow C_2H_5OH + CO_2 + CH_2N_2 \\ \quad\;\; | \\ \quad\;\; OC_2H_5 \end{array} \qquad (1)$$

$$CH_2N_2 \longrightarrow CH_2 + N_2 \qquad (2)$$

Expecting this to be an enzymatic reaction, it appeared convenient to study it in the Warburg apparatus, the likely final product being nitrogen. The other gaseous product of the reaction, carbon dioxide, is conveniently absorbed by 10 per cent potassium hydroxide, placed in the usual way in the middle well of the vessel. Tissue homogenates were prepared in Sorensen's phosphate buffer, *p*H 7.2 (1 : 10), and introduced into the main compartment of the Warburg flask (3 ml.). Solutions of NMU (1 : 100) were placed in the side-arm (0.5 ml.). (The solutions of NMU were freshly prepared from commercial *N*-methylnitroso-urethane by dissolving it in 50 per cent ethyl alcohol, 1 : 20; this gave a clear solution which was then diluted further with distilled water 1 : 5.) The effect of the buffer on NMU and of 10 per cent alcohol (0.5 ml.) on tissue homogenates was tested concurrently each time. The contents of the side-arms were added to the main compartment after 15 min. equilibration at 38.5° C. With tissue homogenates rapid gas evolution immediately followed the addition of NMU and was almost complete in 15 min.; the decomposition of NMU in buffer solution was very slow and slight gas evolution persisted for many hours.

When heparinized rat blood and plasma were tested in this way, rapid evolution of gas from NMU occurred only in the presence of blood corpuscles. The specific agent responsible for the decomposition of NMU is evidently cellular. The reaction was not affected by cyanide, azide or fluoride; it was, however, abolished by copper, indicating that SH-groups may be involved.

Indeed, when 1 per cent solutions of cysteine or glutathione in phosphate buffer at *p*H 7.2 were substituted for blood or tissue homogenates, the evolution of gas from NMU took place in the same way immediately after mixing. This proved that the reaction is chemical rather than enzymatic. Biotin, having sulphur in the ring, cystine, thioacetamide, or some representative cell constituents, such as glycine, tyrosine, guanine, pantothenic acid, etc., had no effect on NMU under the conditions tested.

The question arises: Are some of the SH-cellular compounds directly involved in the carcinogenic action of NMU, diazomethane and possibly of certain other alkylating agents? Diazomethane is known to be a very versatile reagent; it can methylate not only SH-groups but also any acidic or phenolic hydroxyls, amino- and imino-groups; it can add to double bonds, enlarge ring and carbon chains, form methyl branchings. It can conceivably form intra- and intermolecular methylene-bridges.

Which of the multiplicity of possible reactions is related to the carcinogenic action of this compound? The fact that decomposition of the strongly carcinogenic NMU takes place at the SH-groups supports the already existing evidence[5] that these may be involved in the carcinogenic process. However, if carcinogens combine with certain SH-compounds *in vivo*, the type of their binding is likely to differ fundamentally from that of non-carcinogenic agents, many of which are excreted as mercapturates. The action of carcinogens is irreversible and compatible with the survival of the affected cells; the interaction products possibly remain irreversibly *in situ*, and prevent the physiological replacement of some specific SH-compounds, the action of which they block.

Since this communication was submitted for publication, Emmelot and Mizrahi[6] reported that cysteine can counteract the action of dimethylnitrosamine. As the latter can act as a methylating agent (probably through the release of diazomethane after enzymatic oxidation)[7], these results confirm the view based on the more direct evidence here reported, that certain sulphydryl compounds are involved in the action of diazomethane and probably also of other carcinogens.

I wish to thank Miss A. Mackinnon for valuable technical assistance.

Antagonism between Antibacterial Drugs

WHEN two antibacterial agents are combined, the effect of the combination may equal the sum of the antibacterial effects of its components (addition), it may exceed this sum (synergism), or it may be smaller (antagonism)

According to Jawetz and Gunnison[1,2], the antibiotic and chemotherapeutic drugs can be divided into substances the effect of which is mainly bactericidal (penicillin, streptomycin, neomycin, and bacitracin) and substances that generally have only a bacteriostatic action (chloramphenicol, tetracycline, erythromycin and sulphonamides) Combinations of bactericidal substances often show synergism, but are never antagonistic Antagonism is also extremely rare when two bacteriostatic agents are combined But there is a chance of this type of interference when a bactericidal substance is combined with a bacteriostatic one

Recently a more up-to-date schema, which also provides data about the latest accessions in the field of antibacterial substances, was developed in our laboratory As a criterion of antibacterial potency the bactericidal action has been used This criterion was applied by means of replica tests[3-7], the standard of measuring the bactericidal action of the separate drugs and their combinations being not the diameter of the replica inhibition zones, but the number of colonies developing in these zones The results have been arranged in the form of a schema

The schema is based on numerous results obtained with some dozens of strains of *Staphylococci*, *Enterococci*, *Salmonellae* and *coli*-bacteria. More than 90 per cent of all strains investigated showed reactions as laid down in the schema With streptomycin, bacitracin, novobiocin and the neomycin-group of antibiotics we noticed a slightly higher frequency of deviations Our experiments confirm the conclusion arrived at by Jawetz and Gunnison that a fairly sharp distinction can be made between drugs acting *in vitro* mainly bactericidally (in the diagram enclosed by circles) and bacteriostatic drugs (in the quadrangles) Experiments with combinations of the drugs mentioned in the schema revealed that it is possible to distinguish four groups of agents Group 1 (bactericidal substances) nitrofurans (nitrofurantoin, furazolidone, furaltadone), polymyxins (including colistin), streptomycin, neomycins (including kanamycin and framycetin), and bacitracin, Group 2 (bactericidal substances) penicillin, novobiocin, vancomycin, ristocetin and amphomycin, Group 3 (bacteriostatic substances) tetracyclines, chloramphenicol and the erythromycin group of antibiotics (erythromycin, magnamycin, spiramycin, oleandomycin), Group 4 (purely bacteriostatic substances) the sulphonamides and cycloserine

With regard to the combinations of these substances the following points are worthy of note

As a rule a substance belonging to one and the same group (that is, drugs in the same circle or quadrangle in the diagram) can be combined with another one of the same group without any risk of antagonism

Drug antagonism is also only rarely encountered combining one of the bactericidal substances of group 1 with one of the substances of groups 2, 3 and 4 In these combinations the bactericidal agent generally strongly predominates and several of them even present clear cases of synergism (for example, streptomycin + penicillin, kanamycin + penicillin, and polymycin + chloramphenicol)[8-11] Generally speaking, therefore, any drug from group 1 combines well with any one drug from the three other groups.

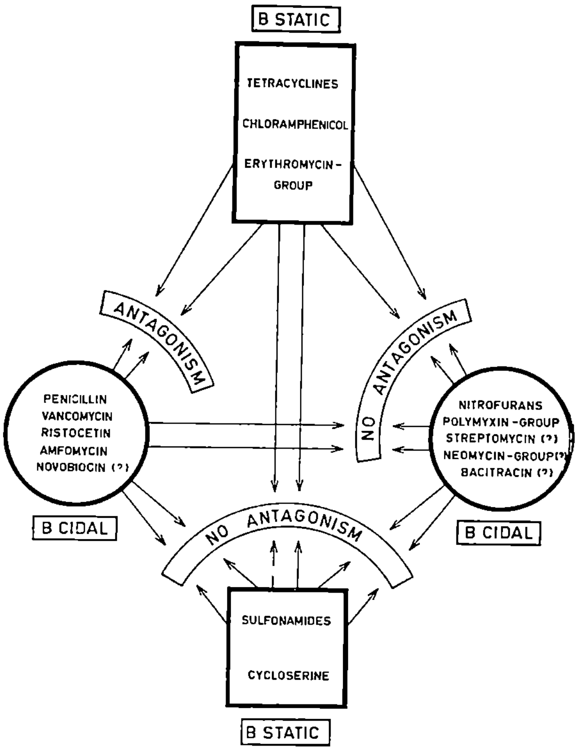

Fig 1 Schema showing presence and absence of drug antagonism in pairs of antibacterial substances

A quite different reaction occurs when a bactericidal antibiotic of group 2 is combined with a bacteriostatic drug of group 3 In these combinations the weaker, that is the bacteriostatic, drug dominates, so here there is antagonism No such antagonism occurs when the drugs of group 2 are combined with those of group 4. Here the bactericidal drug predominates and sometimes there is even synergism (for example, penicillin + a sulphonamide[12])

The different behaviour of the two groups of bactericidal substances (groups 1 and 2) is probably due to the different action of the drugs of these groups on growing and resting bacteria It is a well-known fact that penicillin can only destroy bacteria when they are in the growing stage The drugs of group 3 cause bacteriostasis and thus render penicillin ineffective That the sulphonamides and cycloserine, which act also bacteriostatically, do not neutralize penicillin may be accounted for by the fact that a comparatively long space of time elapses before these drugs cause bacteriostasis. This interval lasts a few hours[13], which is amply sufficient to enable the relatively quick-acting penicillin to inflict irretrievable injury on the bacteria[14].

It is fairly safe to say that the bactericidal action of streptomycin, polymyxin and the nitrofurans is not to any large extent tied down to the growing stage of the bacteria[13,15,16] Consequently, the bactericidal effect of these drugs is little impaired by bacteriostasis caused by one of the substances of groups 3 and 4

On the other hand, the impairment of antibacterial action that occurs when a drug belonging to group 2 is combined with one from group 3 is not so negligible The extent to which it affects the bactericidal action of penicillin in combination of this antibiotic with chloramphenicol, tetracycline, and erythromycin, was made the subject of a closer investigation. This revealed that, with regard to *Staphylococci*, the antagonism between penicillin and the other antibiotics manifests itself over a wide range of concentrations, from at least 0 1 to 10 units of penicillin per ml. Varying the concentration of the bacteriostatic antibiotics from 1 to 100 times the minimum inhibitory level did not cause the antagonism to disappear What we also found was that the antagonism only affects the bactericidal potency of penicillin, the relatively weak bactericidal potencies of chloramphenicol, tetracycline, and erythromycin remaining unimpaired. In these cases, therefore, the type of antagonism encountered is strictly unilateral and only manifests itself in the reduced antibacterial action of one of the two components of the mixture

In the above instances the antagonism results in the antibacterial potency of the stronger component of the combination being destroyed or lowered Sometimes, however, it is the weaker component that is robbed of its effect by the other agent This type of antagonism occurs when, for example, procaine penicillin is combined with a sulphonamide Procaine, which is antagonistic to sulphonamide, cancels the action of this bacteriostatic, and, therefore, weaker agent But on the other hand, a sulphonamide cannot impair the effect of the bactericidal, and therefore stronger, substance penicillin Hence this weaker form of antagonism is also unilateral

New Renal Tubular Amino-Acid Transport System and a New Hereditary Disorder of Amino-Acid Metabolism

WE have investigated the metabolism of amino-acid in a kindred with familial nephritis and deafness Renal hypoplasia and photogenic epilepsy, both familial, and a third independent familial disorder affecting L-proline metabolism were also found in this kindred Familial nephropathy with deafness was recently reviewed[1], but its occurrence with these disorders was not described

Chromatographical methods were used for qualitative[2,3] and quantitative[4,5] analyses of plasma and urine amino-acids in the father, mother, and six offspring including the male propositus, one male and four female sibs The following results were obtained·

Plasma Fasting L-proline concentration was significantly elevated above the accepted normal range (1 5–3 4 mgm per cent)[6,7] on one or more observations, in the propositus and three affected female sibs (Table 1), consistent changes in the concentrations of other amino-acids were not detected in these subjects Plasma amino-acids were normal in other kindred patients investigated

Urine Three subjects with abnormal concentrations of plasma L-proline also exhibited an amino-aciduria involving glycine, hydroxyproline and proline, the latter two amino-acids are not present in normal urine after the first few months of life[8] A patient, with less abnormal plasma proline concentration, excreted only glycine in excess (Table 1) The mechanism of the amino-aciduria has been investigated Fasting amino-acid renal clearance-rates were determined in one affected female sib by the methods described by Cusworth and Dent[6], before and after intravenous infusion of L-proline (71 mgm /kgm.)

Glycine and hydroxyproline clearance-rates were greatly increased while their own plasma concentrations remained normal, their clearance-rates were higher still when plasma proline concentration was further increased (Table 2) Urinary proline excretion, on the other hand, required an elevated plasma proline concentration

Table 1 FASTING PLASMA AND URINE PROLINE, HYDROXYPROLINE AND GLYCINE CONCENTRATIONS IN SIBLINGS WITH HYPERPROLINÆMIA

Subject	Sex	Age (yr)	Plasma proline* (mgm per cent)	Urine amino-acids (mgm amino-acid/100 mgm total nitrogen†)		
				Proline	Hydroxy-proline	Glycine
C M	F	13	6 6	0	0	2,010
			6 4	—	—	—
S M	F	12	11 3	—	—	—
			20 1	1,875	389	4,910
F M (propositus)‡	M	5	7 8	406	42	489
M M	F	3	9 9	307	100	2,350
			7 5	0	0	613
			15 5	235	28	1,700

* Range of normal values (plasma) (refs 6 and 7) proline, 1 5–3 4 mgm per cent

† Range of normal values (urine) (ref 8) proline 0, hydroxyproline 0, glycine 537–1,371 Adult values valid for children beyond infancy.

‡ Patient has renal failure with reduced filtered load of amino-acids

These results imply that glycine and hydroxyproline re-absorption in the renal tubule was impaired and that increased proline re-absorption (secondary to excessive filtration) was a determining factor for the amino-aciduria other amino-acid clearance-rates were not significantly affected in this work

Six normal subjects were also investigated Fasting amino-acid clearance-rates were determined before (30-min periods) and after (consecutive 15-, 30- and 30-min periods), separate acute (3 min) intravenous infusions of equimolar amounts of L-proline (71 mgm /kgm , five subjects), hydroxy-L-proline (82 mgm /kgm , two subjects), and glycine (48 mgm /kgm., three subjects) Table 2 also presents results on one of the subjects who received all three infusions L-proline or hydroxy-L-proline infusion increased the clearance rates of the other two members of the triad Glycine infusion produced similar but less impressive results Clearance-rates of other amino-acids were relatively unaffected. Complete results on normal and affected subjects will be presented elsewhere

These results suggest that glycine, L-proline, and hydroxy-L-proline share a common transcellular

Table 2 FASTING AMINO-ACID INFUSION INVESTIGATIONS

Subject	S M hyperprolinæmic		C S normal		C S normal		C S normal

* Normal range (ref 6), proline $\frac{0}{15–34}$, glycine $\frac{49–116}{10–22}$, hydroxyproline $\frac{0}{0}$, (—) = immeasurable peak (infused amino-acid)

transport system in the renal tubule, the system has higher preference for the two amino-acids than for glycine

The cause and significance of the hyperprolinæmia in the affected patients is under investigation; investigations of the full pedigree indicate its inheritance by a recessive mode, independent of the other familial disorders

This work was supported by grants from the United States Public Health Service (*RG*–6742), and the National Heart Institute (*H*4706), from the United Cerebral Palsy Research and Educational Foundation, and the John A Hartford Foundation One of us (C R S) was a McLaughlin Travelling Fellow and performed some of these investigations in the laboratory of Dr C E Dent, University College Hospital Medical School, London

BIOLOGY

Serological Relationships between the Nine-spined and the Three-spined Stickleback

IN zoological literature we can find some publications[1,2] in which the nine-spined stickleback, *Pungitius pungitius* (L), is considered as belonging to the genus *Gasterosteus* L But most contemporary zoologists consider that this species belongs to *Pungitius* Coste. This difference in attitude has encouraged me to undertake investigation on serological relationships between the three-spined stickleback, *Gasterosteus aculeatus* L , and the nine-spined stickleback, *Pungitius pungitius* (L)

In my investigations I have applied the method proposed by Taliev[3,4] based partly on his own observations and partly on the results of other work

To get the antigen and the antiserum, I used sticklebacks collected from the Olechówka River (near Łódź on July 20, 1960) The whole length of the body of fifty-six specimens investigated was 42–57 mm The sticklebacks, without food for 24 hr , were ground into a mass after they had their heads cut off and their intestines and ribs cut out I used this method because the small body of the stickleback does not permit one to get sufficient quantity of blood[5] necessary to produce the antigen and the antiserum I fixed the mass with Ringer–Lock's tincture in the proportion 1 . 3 ; then I filtered it through infusorial earth I used the product of filtering as an antigen and a vaccine to immunize rabbits After the immunization I took blood directly from the heart of the rabbits Having cleared plasma[6] from the morphotic elements, I fixed it with Ringer–Lock's tincture in the proportion 1 : 1, thus obtaining the antiserum In a similar way I obtained the antigen from the nine-spined stickleback. The nine-spined sticklebacks (25 in number) were caught in the Bobrówka River, district of Łowicz, on 23 9 1960. The length of their bodies was 40–61 mm. In applying serology to establish the relationships among species[7], I also prepared the antigens from grown three-spined sticklebacks collected from the Bobrówka River (23 9 1960), the length of body being 45–53 mm , and from the young three-spined sticklebacks of this year (from the Olechówka River, 19 7.1960). the length of body being 25–30 mm

In my work I applied the ring precipitation technique I diluted the antigens as well as the antiserum with Ringer–Lock's tincture I used the antiserum in constant concentration, 1 · 5 To interpret the results obtained I applied Boyden's method in which the positive reaction of the lowest concentration of an antigen on an antiserum obtained for it is accepted as 100 per cent

As seen from Table 1, the serological distance between *Gasterosteus aculeatus* L and *Pungitius pungitius* (L) is great and it amounts to 56 3 per cent The results obtained by me are approximately the same as those obtained by Taliev when examining the degree of serological relationship of many genera in the Cottoidae and the Salmonidae[3]

Table 1

	Antigens from	Antiserum against *Gasterosteus aculeatus* L from the Olechówka River in the concentration of 1 5	
		The lowest concentration of the antigen with positive reaction	Percentage scale Boyden (per cent)
1	*G aculeatus* L from Olechówka River	1 800	100
2	*G aculeatus* L from Olechówka River, juv	1 300	37 5
3	*G aculeatus* L from Bobrówka River	1 800	100
4	*P pungitius* (L) from Bobrówka River	1 350	43 7

The fact that identical results are found for the same species taken from different fishing places supports the application of serology to taxonomic investigations The non-typical reaction with antigen of young three-spined sticklebacks is also in agreement with work already published

Biotin, a Growth Requirement for Four Soil Amœbæ

SUBSEQUENT to the publication of Adam's defined medium for the growth of Neff's *Acanthamoeba* sp [1], I attempted to grow *Hartmannella rhysodes* in this medium slightly modified in the concentrations of amino-acids[2] A further modification of Adam's medium was also tried in which all the amino-acids used were natural isomers (L forms), except threonine, valine and serine which were used as racemic mixtures (DL forms), and the methionine concentration was halved (13 5 mgm /100 ml) All organic nutrients were obtained from the California Corporation for Biochemical Research (Los Angeles) , the amino-acids used were 'A grade' except DL-isoleucine ('C grade') The culture methods have been described previously[3] Both modifications of Adam's medium failed to support growth of this hartmannellid amœba past the second or third serial culture using either glucose or sodium acetate as the carbon source When biotin was added (0 5 μgm /100 ml), satisfactory growth was obtained in serial cultures The average maximum yield for duplicate cultures in the defined medium, containing 0 1 *M* glucose and grown at 30° C. on a rotary shaker, was 5 76 × 10^6 organisms/ml and the mean generation time was *c* 40 hr This is comparable to growth in the proteose peptone (Difco, Detroit)–glucose medium[3] Identical results have been obtained with Neff's *Acanthamoeba* sp , *Acanthamoeba castellanii* and *Mayorella palestinensis* in both modifications of Adam's medium with either glucose or sodium acetate as the carbon source Therefore all four soil amœbæ appear to require biotin in addition to the vitamins already present in Adam's medium (thiamine and B_{12})

In order to establish whether biotin is a true requirement for the growth of these amœbæ or an artefact peculiar to the defined medium in my laboratory, I used 'Avidin' to bind biotin[4] in the proteose peptone–glucose medium (PPG) described previously[3] 'Avidin' (Nutritional Biochemicals Corporation, Cleveland, containing *c* 1,000–2,000 units/gm) was added to the PPG medium in a concentration of 4 mgm /100 ml The 'Avidin'-treated medium (PPG–A) and the controls were filter-sterilized All four soil amœbæ mentioned above were carried in serial cultures of the PPG–A medium Both the PPG medium and the PPG–A medium, supplemented with enough biotin to saturate the added 'Avidin' (10 μgm /100 ml), were used as controls At each subculture of the serial cultures explants were made into both control media The PPG–A medium failed to support the growth of all four soil amœbæ past the second or third serial culture, whereas growth occurred in the explant controls The experiments were carried out in duplicate on a shaker[3] and in stationary, slanted test-tube cultures at 30° C

At present it is not possible to explain the apparent lack of a biotin requirement in the defined medium described by Adam[1,2] for Neff's *Acanthamoeba* sp The observations given in the present report indicate that, in my laboratory, Neff's *Acanthamoeba* sp , as well as *Hartmannella rhysodes*, *Acanthamoeba castellanii* and *Mayorella palestinensis*, require biotin for growth in the defined medium and in the undefined proteose peptone–glucose medium

Effect of Ribonuclease on Shell Regeneration in *Ariophanta* sp.

IT is supposed that the process of shell growth in molluscs consists of two phases. During the first step there is the elaboration of a protein membrane, and in the second mineralization of this membrane takes place[1,2]. Wagge has suggested that in *Helix aspersa*, which can rapidly repair its shell if this be damaged, the regeneration of the shell is brought about by the amœbocytes, which first lay down an organic framework that later on becomes calcified Since ribonucleic acid is concerned with synthesis of proteins[3,4], which in this case form an integral part of the shell, we have tried to assess its role in the regeneration of the shell in the snail *Ariophanta* sp (Pulmonata)

For experimental work adult snails were chosen, and into each was injected 0 5 ml. of distilled water containing 2 mgm of ribonuclease (Armour, crystalline) Prior to injection, the enzyme solution was placed in a water-bath at 70° C for 20 min so as to destroy the proteolytic activity present in the ribonuclease preparation. The control specimens received 0 5 ml of distilled water only Pieces of shell (slightly less than 1 cm ^{2}) about 2 cm away from the mouth of the shell were removed Eighty snails were used, of which 40 served as controls After injection, the animals were placed in glass bowls with wet filter papers at the top and bottom of the bowl so as to saturate the air with water vapour. They were not fed during the period of regeneration Observations were made on the nature of the regenerating pieces at intervals of 24, 48 and 72 hr , after which parts of the shells with the regenerating pieces in the centre were cut from the specimens treated with ribonuclease and from controls They were wiped dry and dehydrated in an air oven. The area of the regenerated piece was measured by an occular reticule Later, the regenerated piece was carefully cut out and weighed From this, the weight of the regenerated piece per 1 cm.^{2} was calculated for both the treated and the control specimens.

Examination of the regenerated shell showed that the process of calcification was considerably inhibited in specimens which had been treated with ribonuclease when compared with the controls even at the end of 72 hr The dry weight of the regenerated piece at the end of 72 hr in treated snails was 5 63 ± 0 16 mgm per cm^{2}, whereas in the controls it was 10 72 ± 0 40 mgm per cm^{2}

According to Brachet[3] and Casperson[4], there exists a correlation between ribonucleic acid and protein synthesis, the former author[5] has shown that ribonuclease inhibits the incorporation of labelled phenylalanine into the proteins. Therefore, it is possible that ribonuclease, by acting on the ribonucleic acid in the amœbocytes, inhibits the synthesis of proteins which form the essential constituent of the organic framework of the shell

The mineralization of this membrane is brought about by the amœbocytes which transport the calcium ions from the digestive gland and the shell The inhibition in the calcification of the regenerating piece in the specimens treated with ribonuclease may be due to the inability of the amœbocytes to transport the necessary amount of calcium ions to the region of repair, since ribonuclease, by acting on the ribonucleic acid of the amœbocytes, prevents the binding of calcium ions at their cell surface A similar inhibition in the uptake of calcium ions by *Elodea* cells in the presence of ribonuclease was observed by Lansing and Rosenthal[6].

It is suggested that ribonuclease, by inhibiting the synthesis of proteins which form an essential constituent of the shell and also by preventing the binding of calcium ions at the surface of the amœbocytes which normally transport calcium ions to the area of repair, slows down the process of regeneration

Action of a Detergent (Dodecylbenzenesulphonate) on the Gills of the Trout

In the course of our work on the detrimental effect of surface-active agents on fishes we examined changes induced in the gills of the trout by sodium dodecylbenzenesulphonate (DBS) We found a reduction of the epithelium accompanied by a loss of the mucous cells on the top of the gill lamina starting at a concentration of 5 mgm DBS/l The same amount causes the respiratory folds of the lamina to stick together An increasing destruction of epithelial cells follows the rise of concentration, until at 20 mgm DBS/l. after 1 hr the epithelium is destroyed to such an extent that the position of the respiratory folds is recognized only by the more resistant pillar cells Multiple hæmatomas mark the destruction

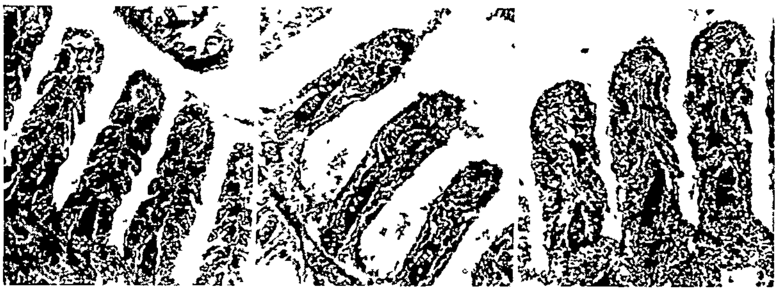

Fig 1 *a*, Untreated control, *b*, concentration of DBS, 5 mgm /l , length of action, 8 hr , *c*, concentration of DBS, 20 mgm /l , length of action, 30 min

The deleterious action of DBS results in a diminished uptake of oxygen by the gills followed by death from suffocation when the concentration of DBS is strong enough or in case of prolonged action even in smaller amounts The deterioration of respiration might be accompanied by a similar impairment of the salt balance and of the metabolism of urea since the gills take part in both mechanisms Details of this work will be published in *Archiv fur Fischereiwissenschaft*, 11 (1961)

The Species of the Teleostean Genus *Lebetus*

The genus *Lebetus* (Gobiidae) was founded by Winther[1] to include two species, *Gobius orca* and *G scorpioides*, described by Collett[2] in 1874 from examples dredged on the Norwegian coast, and is characterized by the absence of an anterior membrane to the pelvic fins, which are united in the mid-line along their entire length. *Lebetus* occurs in the European Atlantic boreal region, being known from Iceland, Norway, the Skagerrak and Kattegat, the British Isles, and Brittany, but also extends into the Bay of Biscay and perhaps as far south as Gibraltar[3] These fishes are of small size (up to 38 mm total length[3]) and frequent rough grounds , in consequence they are not often taken, and are reputedly rare. However, in the past three years, more than fifty individuals of the genus have been obtained in the course of dredging off the southern end of the Isle of Man This collection, together with earlier specimens from the same region and from several Scandinavian museums and the British Museum (Natural History), has provided considerably more material than has been available to previous workers on this genus

Various characters have been used to identify the two species of *Lebetus* Holt and Byrne[4] attached some importance to the coloration of the second dorsal fin On this basis it has been possible to separate the above individuals into two groups, termed *orca*, where this fin has a thick black superior edge above bright white areas and wide oblique bands of yellow (grey when preserved), and *scorpioides*, with a much thinner dark edge and four narrow lines of black and reddish orange across a predominantly hyaline fin The absence from my collection of female *orca* and mature male *scorpioides* suggested connexion of the two coloration groups with sex and sexual maturity Table 1 shows that mature or developing male *scorpioides* do not occur, and that female *orca* are unknown at any stage of maturation This distribution would seem to indicate that the *orca* coloration is the male livery of a species the females and immature males of which bear the markings of *scorpioides*

Table 1 Relation of Sex and Maturity to Coloration Groups

Group	No of males (mature and maturing)	No of males (immature)	No of females (all stages)
orca	35	1	0
scorpioides	0	10	32

After reaching this conclusion, it was discovered that such a view was put forward by Smitt[5] in 1900, but was not accompanied by any details and appears to have been overlooked by later authors The hypothesis is further supported here by the fact that the known examples of *orca* are 18 0–30 0 mm in standard length whereas male *scorpioides* do not exceed 23 0 mm Tåning[6] has reported juvenile *orca*, but based his identification on meristic characters the validity of which is doubtful and is dealt with later Female *scorpioides* attain the same maximum length as that of *orca* Incipient development of the *orca* pattern in the second dorsal fin can be noted among some of the immature male *scorpioides* The first dorsal fin in the *orca* fishes is a uniform yellowish grey edged with white, but in *scorpioides* is usually banded, with a dark spot on the interradial membrane between the fifth and sixth rays This second pattern is stated to be found in the breeding male of *scorpioides*[4], in fact, it is well represented in adult females, and among male *Lebetus* occurs only in the immature Other aspects of coloration in which the two species have been regarded as differing can be seen in both *orca* and *scorpioides* groups

Tests have also been made on other characters used in the past for distinguishing the two species Diagnostic features attributed to *orca* have been an extra ray in the first dorsal fin, rather more articulated rays in the second dorsal and anal fins, but fewer in the pectoral fin and fewer scales in lateral series[4,6] In body proportions *orca* has been regarded as consistently slimmer[4], and a supposed disparity in the position of the anus with reference to the middle of the body was utilized in a key by Smitt[7] From Table 2 it is apparent that the two groups cannot be regarded as specifically distinct on these criteria The wider range and slightly lower means for fin ray counts in *scorpioides* are due to the occurrence in this group of all the smallest fishes, among which such variation is more pronounced

Table 2 Means and Ranges of Values for Characters used in the Identification of *L orca* and *scorpioides*, determined for the two Coloration Groups A Linear Relation exists between Body Measurements and Standard Length

Characters used in identification	*orca*			*scorpioides*		
	No of obs	Mean	Range	No of obs	Mean	Range
*Meristic						
No of first dorsal rays	25	All 6		32	All 6	
No of second dorsal articulated rays	25	9 2	8–10	31	9 0	7–10
No of anal articulated rays	25	7 2	6–8	31	7 1	5–8
No of pectoral rays	52	19 0	18–20	60	18 7	15–21
No of caudal branched articulated rays	24	9 0	9–10	33	9 0	8–10
No of scales in lateral series	38	26 7	25–29	41	26 8	25–29
Body proportions (in standard length)						
Depth at origin of pelvic fin	21	5 6	5 1–6 7	28	5 7	5 1–6 3
Depth at origin of anal fin	23	6 5	5 9–7 3	26	6 6	5 7–7 5
Depth (least) of caudal peduncle before origin of caudal fin	23	10 0	9 2–11 0	29	10 2	8 5–12 3
Distance from snout to anus	22	1 9	1 7–2 0	18	1 9	1 8–1 9

*British material only

Another distinguishing character of *L orca* is the greater size of the first dorsal fin, which is believed to differ from that of *scorpioides* in being considerably higher than the body[8], and higher than the second dorsal fin[3] In the present work, length of fin ray has been used as an index of height of fin With adults in both the *orca* and *scorpioides* groups, rays II and III of the first dorsal fin are longer than any from the second dorsal fin, and greater than the depth of the body at the origin of the pelvic fins In length of ray II, there is little difference between the groups whereas for ray III and the other rays of the first dorsal fin, as well as in the second dorsal fin, there is a more or less pronounced divergence, *orca* having the longer rays This is very noticeable in the last three rays (IV, V, and VI) of the first dorsal fin and, together with corresponding growth of the interradial and posterior membranes, gives the fin a much greater spread in the *orca* fishes

Comparison of other characters, such as the patterns of sensory papillæ over the head and body, does not reveal any differences between *orca* and *scorpioides* Both 'species' have been recorded throughout the geographical range of the genus, and, in so far as can be judged, display no ecological separation

The two groups are thus different in coloration and in development of the dorsal fins, especially the first As mentioned above, *orca* consists entirely of males, almost all maturing or mature, and *scorpioides* of females and immature males The type specimens of *Gobius orca* and *G. scorpioides* (Zoological Museum, University of Oslo) have been examined, and are a male, maturing if not mature, and two females respectively Sexual dimorphism in colour and length of fin ray is well known among teleosts, and has recently been discussed by Egami[9] for Japanese gobies It seems safe to conclude, therefore, that the two names apply to one and the same species, for which the name *orca* Collett 1874 ranks by page priority as the senior synonym to *scorpioides* Collett 1874

A fuller account of this work, and a re-description of the genus and species, are intended for publication elsewhere

Manner of expressing Rate of Ribonucleic Acid Biosynthesis

ENRICHMENT of a medium supporting slow, balanced growth of bacteria (*Aerobacter aerogenes*[1] or *Salmonella typhimurium*[2]) is followed by a period of accelerating growth during which the ribonucleic acid (RNA) · protein ratio of the bacterial protoplasm increases considerably It has recently been stated in papers from this laboratory[1] and elsewhere[2] that the rate of RNA synthesis during this adjustment period is even higher than it will be later when the new, high growth-rate is established (The phrase, 'rate of RNA synthesis', refers to the rate of accumulation of total RNA, of which approximately 80 per cent is ribosomal In the conditions of growth employed in the experiments being discussed, measurements of total accumulation are essentially measurements of ribosome synthesis, since turnover is slight) This assertion is based on the fact that when the logarithm of RNA per ml of culture is plotted against time, the slope immediately after enrichment of the culture is usually greater than that which will be maintained afterwards

We wish to point out that the value obtained from such a slope represents the amount of RNA made per hr per unit of RNA ($dR/dt \times R^{-1}$) and is not necessarily a meaningful expression of the rate of the biosynthetic process In fact, unless the synthesis of RNA is truly an autocatalytic process, this manner of expressing its rate can be quite misleading If alternatively, for example, one expresses the rate of RNA formation as the amount made per hr per unit of protein ($dR/dt \times P^{-1}$), the data cited above (as well as new experiments to be reported[3]) give no indication of an overshoot in the rate of RNA synthesis by a culture in accelerating growth Rather, the rate of RNA synthesis (expressed in this manner) simply increases, upon enrichment of the medium, to the value characteristic of the new growth-rate

To illustrate our point we have drawn an idealized curve which describes the accumulation of RNA and protein in such an experiment (Fig 1) The rate of RNA synthesis, calculated per unit of RNA and per unit of protein, is given for three points (*A*) balanced growth before enrichment, (*B*) unbalanced growth immediately after enrichment, (*C*) balanced growth after adjustment of the culture to the new medium For purposes of comparison, each expression has been multiplied by a constant (c_1 or c_2) chosen so as to yield values at point *A* of 1 It is evident that the two ways of expressing the rate of RNA synthesis give qualitatively different impressions of what happens to this process following enrichment of the medium Expressed per unit of protein, the rate of RNA synthesis quickly increases to the new higher value, while expressed per unit of RNA it overshoots (in this example by 100 per cent) The magnitude of the overshoot depends on the absolute increase in the growth-rate (over the range where RNA content of the bacteria is a function of the growth-rate) and on the rapidity with which the rate of RNA synthesis expressed per unit of protein reaches its new value

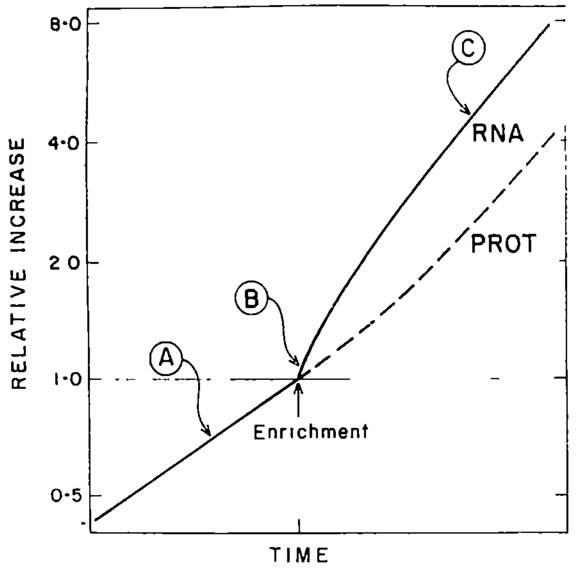

Fig 1 Increase in ribonucleic acid (RNA) and protein (PROT) per ml of culture before and after enrichment

The figure is idealized from data in the papers cited, and fulfils the following specifications (1) The growth-rate finally reached after enrichment is exactly double that before (2) The RNA protein ratio at the higher growth-rate is double that at the lower (3) The rate of RNA synthesis, expressed as the amount of RNA made per hr. per unit protein, increases instantly to the value characteristic of the higher growth-rate Actually, such a curve may be determined simply by the third of these specifications, together with the assumption that the rate of protein synthesis (dP/dt) is proportional to the RNA content of the culture

	$c_1 \frac{dR}{dt} \frac{1}{R}$	$c_2 \frac{dR}{dT} \cdot \frac{1}{P}$
A	1	1
B	4	4
C	2	4

Whether or not one concludes that RNA synthesis is faster during accelerating growth depends on how the kinetic data are expressed, and a choice between methods of expression must await elucidation of how RNA is made

Effect of Temperature and Potassium Gibberellate on Phases of Growth of Algerian Ivy

THE application of gibberellic acid to mature, fruiting shoots of *Hedera* was found[1a,b] to cause a reversion from the shrubby fruiting form to the juvenile vining type of growth Our experiments have confirmed this response but indicate that it depends on the maintenance of a sufficiently high temperature following treatment

Plants of *Hedera canariensis* were treated in midsummer in a 60° F minimum glasshouse with potassium gibberellate in concentrations of 0 0, 0 18, 0 91 and 1 8 mgm a plant, applied in capillary melting point tubes inserted in decapitated stems, using ten plants per treatment In 120 days, all the treated plants were juvenile, but only 30 per cent of the controls exhibited any juvenile characteristics Identical treatments were applied in a lath-house outdoors in January in uncontrolled temperatures in which the minima ranged from 38° to 55° F for most of the experiment Although the plants grew

Table 1 RESPONSE OF ALGERIAN IVY TO TEMPERATURE AND POTASSIUM GIBBERELLATE

Treatment	Temperature	Juvenile or transitional plants	Adult plants	Mean growth of longest shoot (cm)
Potassium gibberellate	50°	0	24	27 5
	60°	19	4	34 8
	70°	21	1	50 1
	74°	18	2	35 1
Control	50°	1	22	12 2
	60°	3	20	16 7
	70°	6	18	19 1
	74°	6	18	15 5

well, none of the treated plants had reverted to a definitely juvenile condition and all the untreated plants remained fully adult after 120 days

Since these observations indicated considerable difference in the ability of gibberellins to promote reversions at different seasons of the year, the effect of temperature was determined experimentally Adult established plants, twenty-four in each treatment, were cut back to one shoot with one or two buds A patch of bark was removed and 1 mgm of potassium gibberellate was applied All plants were placed under 16-hr photoperiods at 1,000 ft -c using constant temperatures of 50°, 60°, 70° and 74° F The reversions produced by the treatments together with shoot growth measurements are shown in Table 1 A few plants died and some of the forms classified as transitional had abnormal growth indicative of excessive concentrations of the chemical

70° F was the best temperature for elongation of shoots Potassium gibberellate doubled the number of bud breaks at all temperatures and was effective in increasing elongation of shoots at all temperatures Reversions were produced in all but the lowest temperatures Several investigators have observed that higher temperatures favoured the production of juvenile growth, including Fisher[2] in *Ranunculus*, Hudson and Williams[3] in *Rubus*, and Njoku[4] in *Ipomoea caerulea* Doorenbos[5] observed reversions on *Hedera* following grafting on juvenile understocks Stoutemyer and Britt[6] verified this effect but showed that it depended on sufficiently high temperatures The observation of Robbins[1b] that reversions were obtained with gibberellin more readily in summer than in winter may be explained as a response to temperature

Effect of Gibberellic Acid, Kinetin and Other Substances on Seed Dormancy

THE seeds of many plants, especially woody species from temperate regions, are dormant when harvested and require a period of chilling ('stratification') before they become capable of germination As part of an investigation into the physiological basis of seed dormancy, attempts were made to replace the chilling requirement by treatment with gibberellic acid and other substances known to break dormancy Gibberellic acid has been shown to stimulate germination in several members of the Rosaceae[1,2] and in various tree species[3–5].

The effects of gibberellic acid on dormant seeds of hazel, Kent cobs (*Corylus avellana*) and beech (*Fagus sylvatica*) have been examined In germination experiments seeds were sown on filter paper or cotton wool soaked in distilled water or gibberellic acid solution and kept in the dark at room temperature In unchilled nuts of beech and hazel only a few embryos were capable of germination, even after removal of pericarp and testa When treated with 100 mgm /l gibberellic acid, embryos and seeds germinated within 3 weeks Beech embryos responded to a concentration of 1 mgm /l In both beech and hazel, intact nuts failed to germinate, even in the presence of 500 mgm /l gibberellic acid

It was also confirmed that gibberellic acid will stimulate germination of birch seed in the dark[3], but that it has no effect on dormant sycamore seed[6] Delayed epicotyl extension in acorns (*Quercus petraea*) was overcome by treatment with gibberellic acid.

It has been shown[2] that although gibberellic acid will accelerate germination of embryos from dormant Rosaceous seeds, it fails to have any effect when the coat structures are intact This observation was confirmed with seeds of apple (*Malus* sp), varieties 'Stoke Red' and 'Medaille d'Or', and rowan (*Sorbus aucuparia*) (See Table 1) Gibberellic acid stimulated isolated embryos to germinate but had no effect if the endosperm was left intact, even if the testa had been removed Concentrations as low as 1 mgm /l failed to stimulate germination of embryos In all the seeds used, coat structures prevented a response to gibberellic acid, in the case of beech and hazel it was the pericarp, whereas in the case of apple and rowan it was the endosperm plus testa which was effective This lack of response could be due to (i) failure of the acid to penetrate the coat structures, or (ii) failure of embryos treated with gibberellic acid to overcome the retarding effect of the coat structures If alternative (ii) was the case, then gibberellic acid only partially replaced the chilling requirement, since fully stratified seeds germinated despite the presence of coat structures

Table 1 EFFECT OF GIBBERELLIC ACID ON APPLE AND ROWAN SEEDS

	Untreated	Gibberellic acid (100 mgm /l)
Apple var 'Stoke Red' (1956)		
seeds	0	0
minus testa, endosperm intact	0	0
embryos	4	17*
,, chilled 10 weeks		
seeds	1	0
minus testa, endosperm intact	1	0
embryos	20	20
Apple var 'Medaille d'Or' (1959)		
seeds	0	0
embryos	16	20
,, chilled 10 weeks		
seeds	18	—
Rowan (1960)		
seeds	0	0
embryos	1	17*

No germinated out of 20 Apple after 1 week, rowan after 3 weeks
* Significant effect at 99 per cent level of probability (using χ^2 test)

Hazel, beech and rowan seeds were treated with other germination-stimulating substances potassium nitrate, thiourea and kinetin Nitrate had no effect on hazel, beech or rowan Thiourea and kinetin were both effective in stimulating germination in these species, although kinetin, at the concentration used (10 mgm /l), had no effect on intact seeds (see Table 2)

Table 2 EFFECT OF VARIOUS SUBSTANCES ON DORMANT SEEDS

	Untreated		Gibberellic acid (100 mgm /l)		Kinetin (10 mgm /l)		Thiourea (7 5 gm /l)		Pot nitrate (2 gm /l)	
	2*	4	2	4	2	4	2	4	2	4
Beech										
nuts	0	0	0	0	0	0	0	0	0	0
seeds	0	0	5	16*	0	0	11*	13*	0	1

embryos	2	9	20*	20*	4	18*	8	18*	4	6
Rowan										
seeds	0	0	0	0	0	0	0	0	0	0
embryos	1	1	9*	19*	16*	19*	5	9*	0	1

2, No germinated out of 20 after 2 weeks, 4, No germinated out of 20 after 4 weeks

* Significant effect at 99 per cent level of probability (using χ^2 test)

The effect of gibberellic acid on dormant seeds might be an indication that endogenous gibberellins play an important part in the chilling process Kinetin and thiourea, however, both unrelated chemically to gibberellic acid, can also stimulate germination Interest in the gibberellins lies in the fact that they have been shown to occur naturally in several seeds and that they promote other aspects of plant growth Also gibberellic acid will overcome 'physiological dwarfing' in seedlings grown from unchilled embryos of Rosaceous seeds[2,7]

The work was carried out under the supervision of Prof P F Wareing, part of it while I was supported financially by a grant from the Agricultural Research Council

Bioassay of Gibberellic Acid using Excised Embryos of *Avena fatua* L.

A NUMBER of bioassays have been described for the detection of the gibberellins A_1 to A_9, particularly for gibberellic acid Almost every assay so far reported for gibberellic acid is of the type which utilizes shoot growth in intact normal, or more often dwarf, species of plants There is thus a need for alternative gibberellin bioassays utilizing other physiological responses This communication demonstrates that the germination response induced in embryos of *A fatua* L treated with gibberellic acid provides an extremely sensitive and rapid micro-test for the acid

The method used by us for assaying chromatograms, or small volumes of solution containing gibberellic acid, is as follows Non-dormant *A fatua* L seeds are allowed to imbibe water for about 15 min to soften the testa Embryos are then excised with a sharp scalpel under a dissecting microscope leaving a thin layer of endosperm attached to the scutellum When dried at room temperature these excised embryos can be stored for several months without affecting their response in the bioassay Twenty-five dry embryos are placed on a standard sized paper (1 × 7/8 in Whatman No 1 chromatography paper) which is then wetted with 0 25 ml of water (for chromatogram segments) or gibberellic acid (for assay of water solutions containing gibberellic acid) Each paper is kept in a small covered dish in a humid atmosphere at 20° C. in darkness. Each treatment is comprised of three such replicates Germination percentages are scored by counting elongated radicles at intervals after 12 hr

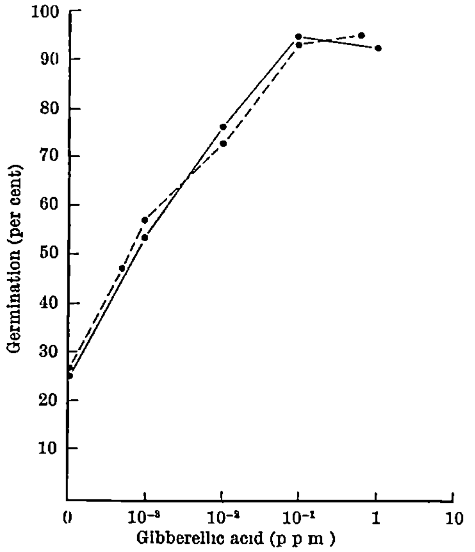

Fig 1 Bioassay of gibberellic acid using the germination response of excised embryos of non-dormant *A fatua* L ---, genetically heterogeneous population of seeds, germination recorded at 14 hr , ——, seeds from an inbred line, germination recorded at 20 hr Each point represents three replicates, each of 33 embryos. *S E* of all points is < ± 3

Two typical dose-response curves of non-dormant embryos to solutions of gibberellic acid are shown in Fig 1 The optimal response to the acid lies between 10^{-1} and 1 p p m It should be noted that concentrations lower than 10^{-3} p p m (0 00025 μgm /replicate of 0 25 ml) can be detected, and that up to 10^{-1} p p m there is a linear germination response to the log concentration of dose of acid There can be some advantage in using an inbred population of seed (solid curve) as opposed to a mixed population of seed (broken curve)

In our material, embryos which have not been after-ripened more than about 18 months show a degree of dormancy which, after maturation of the seed, decreases with period of after-ripening During this period there is a distinct shift in the pattern of reaction, embryos respond to a lower concentration

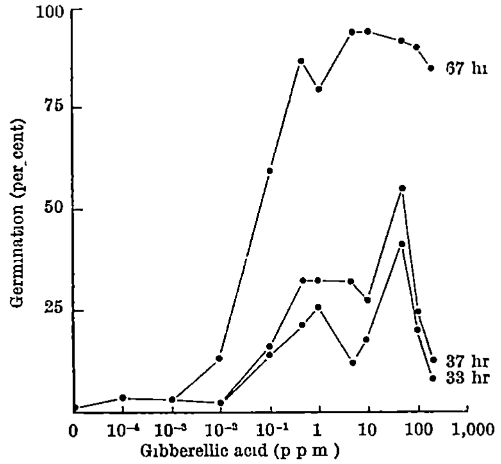

Fig 2 Dose-response curves of semi-dormant embryos of *A fatua* L to gibberellic acid

of gibberellic acid Also the time taken for germination to occur decreases considerably Fig 2 represents the response of seeds after-ripened for 4 months It is apparent that the embryos show two responses to gibberellic acid with distinctly different concentration optima, the higher optimal concentration lying near 50 p p m and the lower between 10^{-1} and 1 p p m Moreover, if seed is mature but not after-ripened the embryos show a response only to the high range of concentrations (10^{-1} to 50 p p m) An explanation of the physiological responses accounting for these differences has been presented in ref 2 The response to high concentrations of gibberellic acid is known to be due to the ability of the acid to eliminate the requirement for exogenous sugar in germination

Accordingly, the assay procedure is simplified by using embryos which have after-ripened to the point where exogenous sugar need not be supplied However, the dose-response curve of dormant embryos to the acid in the presence of sugar is essentially the same as that of non-dormant embryos with the acid alone, with the exception that the time required for the assay is slightly longer for semi-dormant and substantially longer for very dormant seed

Kinetin and indole-3-acetic acid (IAA) show no positive effects in the test IAA induces some inhibition of germination at concentrations of 1–10 p p m , which, however, is reversed by gibberellic acid The specificity of response of the embryos to different substances has not been otherwise investigated It would appear that the cultivated wheat and oat varieties are unsuited for use as bioassay material as their response to low concentrations of the acid disappears fairly soon after the seed is matured

In conclusion, the following points show some advantages of the *A fatua* bioassay (1) The assay can be completed in less than 18 hr (2) Assay material occupies a small space with environmental conditions suited for routine laboratory testing, that is, a simple incubator (3) Because material can be accumulated without loss of activity, large-scale assays are quite feasible (4) Small volumes of solution (0 25 ml /replicate) together with low specific amounts (0 00025 μgm) can be used for the assay This can be important when dealing with extracts of plant material with low specific activity

ENTOMOLOGY

Occurrence of a Hyperglycæmic Factor in the Corpus Cardiacum of an Insect

ALMOST two decades have elapsed since Abramowitz *et al* [1] first reported the occurrence of a 'diabetogenic' factor in the sinus gland of a crustacean To the best of my knowledge the experiments described here are the first to show that a substance with a similar effect occurs in the corpus cardiacum of an insect The corpus cardiacum was selected for investigation because of its analogy to the sinus glands of Crustacea and its known content of biologically active materials[2-4] In view of the recent finding that the main blood sugar in insects is the non-reducing disaccharide trehalose[5-7] the effect of corpora cardiaca extracts on both reducing and non-reducing sugars in the blood has been investigated

All observations were made on the adult male cockroach, *Periplaneta americana* L , 4–5 weeks after the final moult Blood was removed from the cockroaches by the method in ref 8 and tungstic acid filtrates prepared Part of this filtrate was used for determination of reducing sugar, obtained by determining reducing value before and after fermentation with baker's yeast Because trehalose yields glucose on hydrolysis it may be estimated as reducing sugar Non-reducing fermentable values were obtained by hydrolysing a portion of the original filtrate with *N* hydrochloric acid at 15 lb /in ^{2} for 30 min , neutralizing the hydrolysate with *N* sodium hydroxide and treating in the same manner as the unhydrolysed filtrate The reducing power of the hydrolysed filtrate after correction for reducing power of unhydrolysed filtrate is considered to be a measure of blood trehalose These values are expressed as mgm per cent glucose equivalents Reducing power was determined by the method of Somogyi as modified by Nelson[9]

The corpora cardiaca extracts were prepared by homogenizing a number of pairs of glands, from which the corpora allata had been removed, in a suitable volume of Pringle's insect Ringer The extract was boiled for 5 min and then centrifuged at 12,000*g* for 15 min The supernatant was removed, diluted with Ringer solution to the desired concentration and stored in a deep-freezer until required for injection Table 1 shows the effect of 10 μl of extract, equivalent to one-tenth of a pair of glands, on the level of blood sugar at different times after injection The control animals received Ringer solution only It can be seen that except in two instances the level of reducing sugar was lower in those insects which received extract than in the controls The effect of the extract on the trehalose content of the blood was very striking 30 min after injection it had risen 45 3 per cent and reached a maximum of 150 per cent 5 hr. after injection Thereafter the trehalose content declined, returning to the normal level 48 hr after injection The figures for the control insects compare very well with those obtained for normal uninjected insects, the latter being 74 mgm per cent reducing sugar and 1,174 mgm per cent glucose equivalents of trehalose When older (3 months) cockroaches were used the trehalose concentration was found to be of the order of 1,400 mgm per cent glucose equivalents This figure is in good agreement with that given in ref 10 The extract was found to be effective even at a greater dilution than that used in the experiment described here, an injection equivalent to one-five-hundredth of a pair of glands increasing the blood trehalose by 30 per cent When used in a concentration of one pair of glands/injection the mean increase in blood trehalose was 152·5 per cent, which is comparable to that obtained with one-tenth pair of glands, suggesting that one-tenth of the active material contained in

Table 1 EFFECT OF CORPORA CARDIACA EXTRACTS ON BLOOD SUGAR
Figures are mgm per cent glucose equivalents

Time after injection (hr)	No of insects	Reducing sugar		Trehalose		
		Control	Extract	Control	Extract	Increase (per cent)
0 5	12	25 2	31 4	1,237	1,797	45 3
1	12	70 3	31 8	1,225	2 583	110 8
3	12	29 7	41 7	1,293	2,558	97 8
5	12	37 2	29 3	1,050	2,625	150 0
12	12	66 1	29 1	1,118	2,178	94 8
24	12	43 4	32 3	929	1,941	109 0
48	12	52 4	19 5	1,025	1,160	13 2

the corpora cardiaca is sufficient to elicit the maximum response.

In order to determine whether the hyperglycæmic activity of the corpora cardiaca was specific to this tissue a number of other tissue extracts were prepared and tested for activity. The extracts, prepared from approximately 25 mgm. of tissue, were treated in the same manner as those of the cardiaca. The results of this experiment are shown in Table 2. All values, except one for brain tissue, indicate that none of the extracts had any effect on the level of blood trehalose. One of the values obtained for brain tissue was slightly high and may have been due to traces of cardiaca tissue remaining attached to the brain. The corpora allata were also examined for hyperglycæmic activity, but because of the technical impossibility of completely removing the corpora cardiaca, the results were inconclusive.

Table 2. EFFECT OF VARIOUS TISSUE EXTRACTS ON BLOOD TREHALOSE

Figures are mgm. per cent glucose equivalents

Time (hr.)	No. of insects	Control	Nerve cord	Muscle	Brain
5	6	1,241	1,041	1,147	1,470
5	6	1,119	1,218	1,069	1,263

The results of this work clearly show that the corpora cardiaca of the cockroach contain a powerful hyperglycæmic factor. Perhaps this is the 'insect adrenalin' described in ref. 3.

Inhibited Oviposition by Females of *Gryllus assimilis* (F.), induced by Radioactive Males, using L-Methionine-Methyl-^{14}C

THE taxonomy of North American field crickets of the genus *Gryllus* L. (until lately all referred to a single species, *Acheta assimilis* F.) has presented considerable problems in the past, and has recently undergone considerable revision[1-4].

In an attempt to help solve certain problems concerning speciation in this group of crickets, work with radioisotopes was initiated, using a laboratory culture of Jamaican *Gryllus assimilis* (F.), *sens. strict.*, and L-methionine-methyl-^{14}C. From these initial experiments an unexpected and interesting result was obtained. Not only did the treatment cause apparent sterility of the males, but also inhibition of egg-laying by females mated with radioactive males.

The experiments reported here were carried out in the Department of Entomology and Plant Pathology, Macdonald College, Ste. Anne de Bellevue, Quebec, in a greenhouse laboratory maintained at a temperature of 80° ± 1° F., and a relative humidity of 75 ± 5 per cent. The radioactive isotope, in distilled water, at dosages ranging from 0.05 to 10 μc./cricket, was injected into the hæmolymph of last-instar nymphs of both sexes of *G. assimilis* by means of an 'Agla' brand microsyringe (Burroughs Wellcome and Co., Ltd.). The needle was inserted laterally through the intersegmental membrane between the sixth and seventh abdominal segments.

At doses of up to 5 μc., the radioisotope had no deleterious effects on the insects and the nymphs metamorphosed to adult crickets and performed all functions of life quite normally, as did the controls which had been injected with equivalent quantities of distilled water alone. Higher concentrations of the radioisotope were lethal within 24 hr.

The nymphs injected with doses of 5 μc., or less, of the radioisotope all retained their radioactivity after moulting. The adult crickets thus obtained were then placed in individual 1-gallon, candy-jar breeding containers, provided, where appropriate, with oviposition cups after the manner described in ref. 5. All virgin females, both radioactive and normal (non-radioactive), began, on maturing, to lay numerous eggs whenever oviposition cups were available. This is usual in *G. assimilis* and certain other *Gryllus* and *Acheta* species, although parthenogenetic eggs have never been observed to develop. Also, when normal (non-radioactive) males were mated with either normal or radioactive virgin females, normal oviposition occurred. The eggs in both cases were viable, those from the radioactive females being also detectably radioactive as were first-instar nymphs which later hatched from them.

However, when radioactive males, derived from nymphs injected with any dose of L-methionine-methyl-^{14}C used, were mated with either radioactive or normal virgin females which had not yet begun laying, no oviposition occurred. Repeated experiments all produced the same results. Table 1 shows the average fecundity of radioactive and normal females, continually associated with normal and radioactive males. Figures for unmated virgin females (all of which oviposited) are also given by way of comparison. All radioactive individuals were derived from last-instar nymphs injected with L-methionine-methyl-^{14}C at a concentration of 1 μc./cricket.

Table 1. RESULTS OF MATINGS BETWEEN RADIOACTIVE (*R*) AND NORMAL OR NON-RADIOACTIVE (*N*) INDIVIDUALS OF *Gryllus assimilis* (F.) FROM DECEMBER 22, 1960, TO FEBRUARY 1, 1961

Matings 5 Males	 5 Females	Average number of eggs per female
R	*N*	0
R	*R*	0
N	*R*	196
N	*N*	126
—	*R*	123
—	*N*	90

It would seem from the results indicated in Table 1 that the radioisotope produced sterility in the males since no eggs were produced by the females with which radioactive males were associated. The urge to mate, however, was not impaired, the radioactive males mated as readily with both normal and radioactive females as did normal males, nor was the production of spermatophores inhibited. Judging from the average number of eggs laid per female, it would seem that the radioisotope may have led to an increase in the fecundity of females whether they had mated with normal males or not. This is indicated more clearly by the complete data than by the condensed table given here. It is also interesting to note that similar results have been obtained by administering the radioisotope orally via the drinking vials. Nymphs and adults were made radioactive by placing treated vials in the rearing jars for 72 hr.

It has, of course, long been recognized that male insects can be sterilized by irradiation with X-rays and/or γ-rays[6-9], but the present experiments appear to give the first indication that sterility may be induced by such a weak β-emitting radioisotope as L-methionine-methyl-^{14}C.

The second point of interest is that, whereas in previous cases of sterility in insects females have laid infertile eggs[7], in the case of *Gryllus assimilis* no eggs are laid by females after mating with radioactive males, even though unmated females normally lay (infertile) eggs. That radioactivity alone does not produce this result is indicated by the fact that radioactive females, either virgin or mated with normal males, oviposit normally; the implication is that some factor inhibiting oviposition is passed to the females from the radioactive males by way of the spermatophores (which were found to be detectably radioactive). It seems unlikely that non-radioactive L-methionine would have this effect, although this possibility is being explored.

Insufficient is known about the mechanism inducing oviposition in insects to indicate what might have occurred in this case, but it could be postulated that some reaction which permits or encourages the production of eggs when normal spermatophores are received by the female is blocked by the presence of a substance or substances originating from the radioactive spermatophores. That something of this kind is possible is indicated by the fact that inhibited females will begin to lay fertile eggs about 2 weeks after being mated with normal males. Similarly, such females isolated afterwards will begin to lay infertile eggs after about the same period. The fundamental question is posed: What causes oviposition to occur? Exactly what process is it that is inhibited by these hypothetical toxins from the radioactive spermatophores?

Whether there is any likelihood of a successful outcome from an attempt to put the type of sterility induced by radiation in *Gryllus assimilis* to practical use is doubtful. Bushland and Hopkins[7] used X-ray-sterilized males of the screw-worm fly, *Callitroga americana* (C. and P.), in the control of that insect in Florida, but this was made feasible because most females of this species mate only once. Females of *Gryllus assimilis*, on the other hand, mate frequently. The exact number of times has not been determined, but Spann[10] states that Kansas females of a related species (not *G. assimilis* although he uses this name) may mate about seven times daily. Thus, even though a radioactive male should inhibit oviposition in many females, it would not be long before the latter recovered and mated with normal males.

MICROBIOLOGY

Survival of *Rhizobium meliloti* in Soil Culture

THE root nodule bacteria of leguminous plants (*Rhizobium* spp.) have repeatedly been observed to survive as long as 15–16 yr. in various media[1,2]. Bisset[3] has explained this remarkable longevity as due to formation of endospores in a complicated life-cycle.

The culture collection of this Laboratory includes many cultures of *R. meliloti* that have remained viable for much longer periods in a medium of loamy garden soil plus 0.5 per cent mannitol and some calcium carbonate, sterilized by autoclaving; the culture vessels are Freudenreich flasks that have been stored in darkness at room temperature, under which conditions the soil becomes air-dry within about a year. During the autumn of 1960 I examined such cultures of twenty *R. meliloti* strains, seventeen from lucerne and three from *Medicago lupulina*. The age of these cultures ranged from 30 to 45 years, the majority (13) being 38–40 years old.

A pure growth of *R. meliloti* developed from all cultures within a week when small quantities of soil were transferred to slopes of glucose–asparagine agar plus lucerne seedling extract. Plate counts on the same medium were rather erratic but suggested numbers from less than a hundred to about half a million per gm. of soil, with no apparent correlation between age and density of bacteria.

Some pasteurization tests were made on soil suspensions (one part of soil in ten parts of sterile tap water) heated for 5–30 min. in a thermostatically controlled water-bath; duplicate portions were cooled rapidly and ten drops of suspension were transferred to slopes of agar medium that were watched for growth at 25° C. for three weeks (in some cases for six weeks, which made no difference). Eleven strains failed to grow after heating for 5 min. at 50° C. The remaining nine showed somewhat inconsistent growth after heating for 5–20 min., one of them (*L.* 21, aged 39 yr.) even after 30 min. These strains, and five more, were tested at 60° C.; all succumbed after 5 min., except *L.* 21, which, in one instance, survived for 10 min. The rhizobia in the soil are thus about as heat-sensitive as in agar cultures[1], and according to this evidence they do not survive as thermoresistant endospores.

Nutman[4] found *R. trifolii* frequently producing ineffective variants when grown in sterile soil. To see if this had happened in the present cultures, 200 isolated colonies were picked from the plate counts (20 colonies from each of 10 strains) and the isolates were tested for effectiveness on lucerne seedlings in aseptic agar cultures. All isolates formed normal nodules with red pigment; nodule-bearing plants were dark green and healthy-looking and contained 2.7–4.6 per cent nitrogen in dry matter 8 weeks after inoculation, while the uninoculated control plants were dwarfed and yellowish, with 1.2–1.7 per cent nitrogen. One isolate (from strain *L.* 4, aged 44 years) was ineffective immediately after isolation but was normally effective when re-tested a couple of months later. Formation of permanently ineffective variants in *R. meliloti* thus seems to be quite a rare occurrence.

The collection includes no cultures as old as those of *R. meliloti*, but soil cultures of several other organisms proved viable at ages of 10–14 yr. This applies to bacteria (*R. trifolii*, *R. leguminosarum*, *Pseudomonas* *aeruginosa*) as well as actinomycetes (*Nocardia, Streptomyces, Micromonospora*) and fungi (*Trichoderma, Penicillium, Aspergillus*)

Sterilized soil as culture medium thus seems to keep vegetative cells of *R meliloti* alive and effective in a desiccated condition for periods approaching half a century, moreover, it preserves for more than ten years the viability of several other micro-organisms that have never been claimed to form endospores

Inhibition of Lysozyme by 'Suramin'

IT has been shown that a number of non-chaining bacteria form long chains when grown in the presence of 'Suramin', the chains are rapidly split by filtrates of ordinary 'short form' cultures of the organisms It was assumed as a working hypothesis that separation of bacterial cells is an enzymic process and that 'Suramin' acts by inhibiting the cell-separating enzyme[1]

Detailed experiments showed that while *Streptococcus faecalis, B megaterium, Cl welchii* and *Cl sporogenes* grow well in the presence of 'Suramin' at a concentration of 1 gm in 40 ml (w/v), some chaining still occurs at concentrations up to 1 gm in 5,000 ml (w/v) The hypothesis of enzyme inhibition was confirmed when it was found that the chain-splitting activity of the filtrates was indeed inhibited by 'Suramin' at concentrations ranging from 1 to 15 µgm / ml (w/v)

It is also known that chains of various aerobic and anaerobic rods (obtained by growth in magnesium-deficient medium) and chains of *Streptococcus pyogenes* can be split by lysozyme[2,3] Preliminary experiments confirmed these findings and extended them to *Cl sporogenes* and *Streptococcus faecalis* Relatively high concentrations of lysozyme were required to split the chains in the standard time of 30 min (20–100 µgm / ml w/v), the splitting was inhibited by 'Suramin'

Evidence was afterwards obtained (to be published in detail elsewhere) that despite the similarity of effect between lysozyme and filtrates, splitting of chains is not in fact caused by lysozyme but is due to an enzyme of bacterial origin—apparently released by lysozyme from the cells Since, however, 'Suramin' is a powerful inhibitor of lysozyme it was thought interesting to give an account of it

Crystalline lysozyme (Sigma Co) and 'Suramin' (Imperial Chemical Industries) were sterilized by filtration through sintered glass Lysozyme was assayed by estimating its ability to lyse suspensions of *Micrococcus lysodeikticus* (N C T C 2665) The organism was grown at 28° C on meat-extract broth agar for 48 hr and the cells washed three times with saline Suspensions of 10^9 cells/ml were made in saline-phosphate buffer *p*H 5·5, and falling amounts of lysozyme added Results were read after 30 min at 20° C taking 50 per cent clearing of the suspension on an EEL nephelometer as the end point

The results can be summarized as follows lysozyme caused clearing of the suspensions of *Micrococcus lysodeikticus* up to a concentration of 0·1 µgm /ml (w/v) 'Suramin' gave 50 per cent inhibition of lysozyme when present at equal weight Accepting the mass of lysozyme as approximately ten times that of 'Suramin', inhibition occurred when 'Suramin' was present at a ten-fold molar excess

In some experiments 'Suramin' was first left in contact with the bacterial cells, provided that 'Suramin' was afterwards removed by washing the cells with saline no inhibition was observed In other experiments 'Suramin' was allowed to interact with lysozyme before the cell suspension was added, maximum inhibition was reached rapidly in 5–15 min

We are indebted to the Rankin Research Fund for a grant towards the expense of this work

Dihydroxyacetone Production in *Acetomonas*

IT has already been shown[1] that a useful primary criterion for differentiating *Acetomonas* strains from those of *Pseudomonas* is the ketogenic action of the former on glycerol which results in the production and accumulation of dihydroxyacetone Thus the 165 strains of *Pseudomonas* studied all failed to show production of dihydroxyacetone, while 49 out of the 50 *Acetomonas* strains produced it abundantly

As regards the single anomalous *Acetomonas* strain (*A suboxydans* N C I B 3734) it was tentatively suggested that this might not be an *Acetomonas* strain at all, but a mutated *Acetobacter* strain which had possibly lost the typical ability of acetobacters further to oxidize the acetic acid produced to carbon dioxide and water, for production of dihydroxyacetone is much less common in *Acetobacter* than in *Acetomonas* There was, however, no way of knowing whether it was originally dihydroxyacetone-negative when first isolated or whether it has lost dihydroxyacetone positivity in the course of long sub-cultivation

However, we now have definite evidence that the ability to produce dihydroxyacetone can be lost by 'mutation' (in the broadest sense) in the course of laboratory sub-cultivation A strain of *Acetomonas*, isolated from cider, was strongly dihydroxyacetone-positive when first isolated Now, after sub-cultivation on apple juice agar for some two years, this strain is completely dihydroxyacetone-negative, although it has retained its original ability to produce deep brown to black water-soluble pigment on yeast extract/glucose/calcium carbonate agar

It thus appears that production of dihydroxyacetone from glycerol, if negative, is not so conclusive as formerly in suggesting that a strain is a pseudomonad, but merely functions as a first presumptive indication to that effect However, even if dihydroxyacetone-production is negative, the other three primary criteria[1] found always to be conclusive for differentiating *Acetomonas* from *Pseudomonas* strains amply suffice to prevent any possibility of confusing these two completely different types of bacteria.

CYTOLOGY

Chromosome Preparations obtained directly from Peripheral Blood

Abnormalities of both number and morphology of the chromosomes of leukæmic cells in man have been reported[1,2]. All such work reported to date has been made on cells from marrow or from peripheral blood cultured *in vitro*. Such findings are open to the theoretical objection that any observed abnormality might have arisen during the culture process. In order to obviate this possibility, we decided to attempt to take advantage of the situation in leukæmia where the bone marrow is abnormally active, and later developed a method of making preparations without prior culture[3].

This method has now been successfully adapted for application to cells obtained directly from the peripheral blood in cases of leukæmia where again abnormal numbers of cells, many of them in division, may be found.

Venous blood (20 ml.) was collected into the dipotassium salt of (ethylene dinitrilo) tetraacetic acid. The white cells were separated from the red by centrifugation at 400 r.p.m. at 0–4°. The supernatant plasma and white cells were decanted and 0·72 per cent sodium citrate was added for 10 min. After centrifugation at 1,500 r.p.m. and resuspension of the leucocytes in 3 : 1 (ethanol : acetic acid), the material was hydrolysed in *N* hydrochloric acid at 60° C. for 4–6 min (depending on the specimen) and stained with orcein.

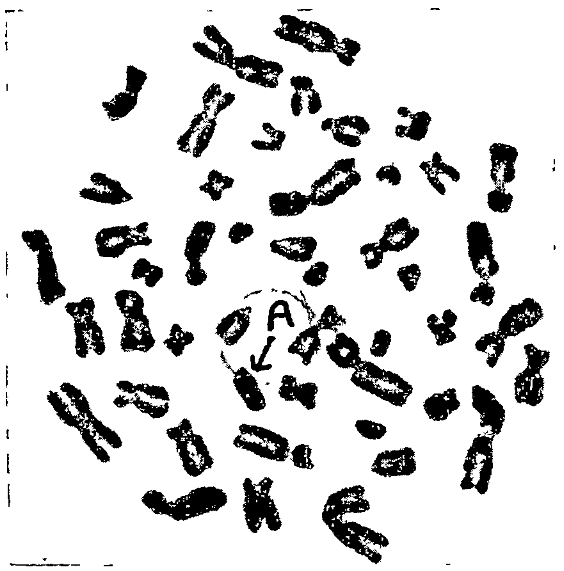

Fig. 1. Direct peripheral blood preparation. Hyperdiploid metaphase ($2n + 1$) in a male with acute leukæmia. The additional chromosome is shown at *A*

It has been found that the dipotassium salt of (ethylene dinitrilo) tetraacetic acid used as an anticoagulant has a colchicine-like action on chromosomes, producing many well-differentiated metaphase plates. There is thus no need for previous administration of colchicine or colcemid. Very satisfactory preparations, suitable for both counting and morphological work, are being obtained by this simple method.

Surface Granulation in Myeloid Leucocytes

The clinical use of cytotoxic drugs which have a more or less specific action on cells of the lymphoid or myeloid series has made more important the differentiation of one type of acute leukæmia from another. Any technique which points to distinct biochemical or physico-chemical differences between myeloid and lymphoid cells is therefore worthy of further study. This communication is concerned with distinct differences in these two types of cells revealed by certain effects of fixation. These have not been reported before.

In 1957 McNary[1] described the application to blood cells of a histochemical stain specific for zinc. The stain contains diphenylthiocarbazone (dithizone) dissolved in absolute acetone, water, 1 *N* acetic acid, sodium potassium tartrate, and a complex-forming buffer (sodium thiosulphate, sodium acetate, potassium cyanide and glacial acetic acid) at *p*H 5·5.

After staining blood smears for 15 min., neutrophil and eosinophil granulocytes, but not lymphocytes, show a golden-brown discrete 'granulation' in the cytoplasm which is easily seen with high-power magnification, provided a dry objective is used. Viewed under oil immersion, or after mounting, the 'granulation' is no longer visible. The same golden-brown 'granulation' is produced if dithizone is left out of the stain.

Accentuation of this effect is obtained with phase contrast and a dry objective × 45, the neutrophils contain numerous black dots and the lymphocytes contain none (Fig. 1*a*). The black dots disappear when viewed through oil, and where the black 'granules' were previously seen the cytoplasm now shows fine patchy areas which are paler than the rest of the cell (Fig. 1*b*).

This phenomenon can be explained if the 'granules' are regarded as irregular elevations due to folding of the cell surface, resulting from the effects of *p*H and fixation. Light passing through a cell is altered in phase by an amount depending on the product of refractive index by thickness[2]. These elevations would therefore appear black under phase contrast because the cell is thicker in this region. Addition of oil with a greater refractive index than the cell would reverse the picture as there would be now less oil over the elevations than over the rest of the cell. In support of this concept, it is known that precipitant fixatives

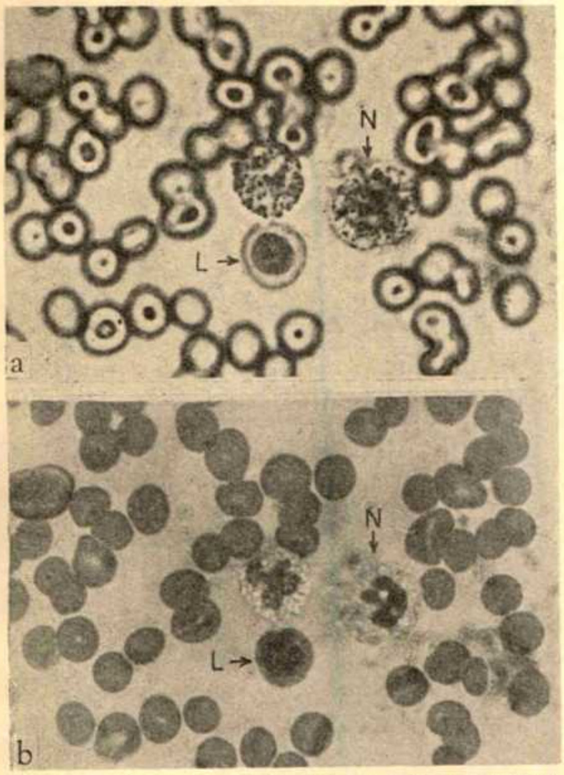

Fig. 1. *a*, Blood smear showing two neutrophils with 'surface granulation' (*N*) and one lymphocyte with clear cytoplasm (*L*). Counterstained with Leishman. Phase contrast × 450. *b*, Same field as in *a* but under oil immersion (× 450). Disappearance of 'surface granulation'

containing acetic acid often produce considerable distortion of the cell[3].

Sodium thiosulphate in the presence of acetone, water and acetic acid is effective in producing neutrophilic 'surface granulation', but the change is dependent on *p*H and is best developed at a *p*H near 5·5. This was determined by testing freshly prepared air-dried blood smears against the various components of McNary's stain. Neither dithizone, sodium potassium tartrate nor potassium cyanide was necessary for the production of 'surface granulation'. Absolute acetone, or acetone plus water, alone does not produce 'surface granulation' although it adequately fixes blood smears.

If blood smears are fixed first in methanol, formalin vapour, or osmium tetroxide vapour, neutrophils no longer show 'surface granulation'. Neutrophils from the dog do not show 'surface granulation' under conditions which produce it in human neutrophils.

The differences described here between human neutrophils and lymphocytes must reflect biochemical differences in cell proteins. These differences are being investigated in lymphocytic and granulocytic cells at various stages of maturation.

This work was supported by a grant from the Anti-Cancer Council of Victoria. I am grateful to Dr. T. E. Lowe for his help.

ARCHÆOLOGY

Absolute Age of Pleistocene and Holocene Deposits in the Haua Fteah

THE general characteristics of the large coastal cave site known as the Haua Fteah, in north-eastern Libya, have already been described, together with a brief résumé of the most important results obtained up to 1952[1,2]. A further season's work in 1955 provided additional fossil human remains associated with Middle Palæolithic occupation débris[3a,b], enabled a much closer analysis of the stratigraphy, and, by opening up a wider area, made possible the excavation of a deep sounding into earlier cultural horizons than any hitherto examined, down to a total depth of 42·5 ft. In the past six years a detailed programme of study of the cultural, palæontological and other collections has been carried out in this Department, and further samples for carbon-14 analysis have been processed.

From an archæological point of view the site is now seen to offer a nearly continuous cultural succession from a pre-Mousterian stage (provisionally labelled Libyan Pre-Aurignacian by analogy with the "Praeaurignacien" identified by Rust[4] in Syria) up to the present. The stratigraphy containing this succession consists for the most part of remarkably regular horizontal layers, distinguished from one another by minor differences in colour and lithology, and ranging in thickness from about 6 to 18 in. (ref. 2). Mammal bones form a considerable proportion of the occupation debris and are the subject of a separate communication elsewhere[5]. The object of the present note is to make available, in advance, the principal data on which the absolute age of the cultural and biological succession is based, since these would appear to be relevant to other investigations being carried out elsewhere in the Mediterranean and adjacent areas.

Carbon-14 age estimates were obtained by H. E. Suess, at the Washington Laboratory, from samples collected in 1952 (ref. 6), and by the late Hl. de Vries, from samples collected in 1955 (personal communication). In the accompanying diagram (Fig. 1) these ages have been plotted against the cumulative depth obtained by adding together the maximum observed depth of each layer. This device has been adopted in order to minimize the effects of localized denudation, and hence approximate as nearly as possible to the relative time-interval represented by each layer.

It will be noted that as far back as 28,500 before the present the points appear to approximate to a logarithmic curve representing a gradually decreasing ratio of thickness to time unit. This is not unexpected since the effects of compression by increasing overburden, plus possible weathering *in situ* by percolating water, should in general lead towards progressive reduction in thickness.

Below a depth of about 25 ft., however, this tendency seems to be reversed by dates *W*85, *GRO* 2022, 2023, and a preliminary reading for layer XXIX, *GRO* 2050 (de Vries, personal communication). Both Suess and de Vries, however, considered that these dates were best regarded as minimum rather than absolute, owing to the well-known greatly increased disturbance of small contaminations, etc., on readings of this great age. On the whole, therefore, the projection of a line drawn from *GRO* 2586 through the midpoint between the readings for layers XX and XXI would seem to provide as reasonable a first approxi-

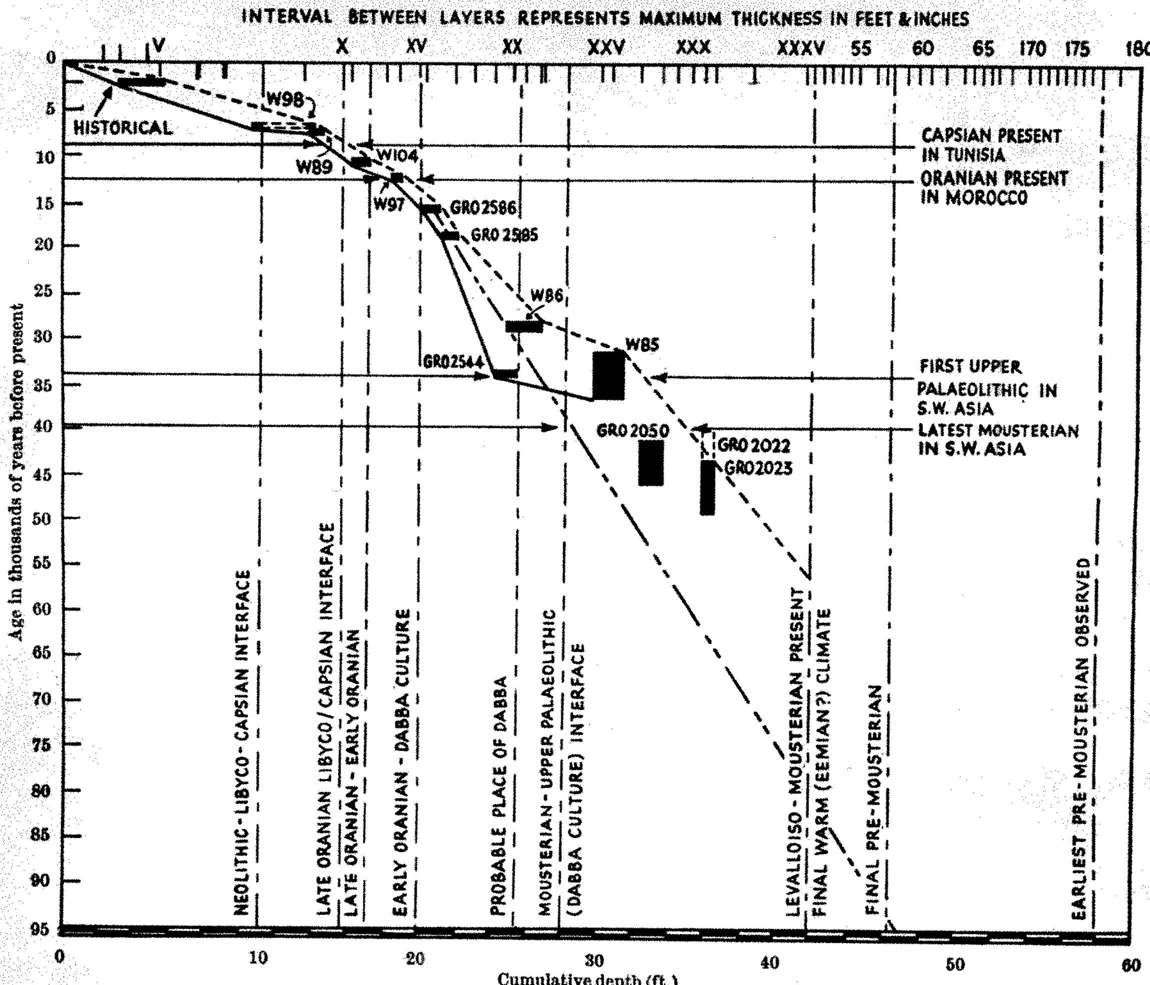

Fig. 1. Graph to show relation between age in thousands of years before the present and cumulative depth (ft.), of carbon samples from the Haua Fteah, Cyrenaica, Libya. The rectangles represent the depth through which the sample was taken and the standard error of the carbon-14 reading expressed in years. The central broken line represents the hypothetical trend beyond the range of the readings regarded as most reliable. The numbers at the top of the diagram are the reference numbers assigned to each layer

mation to the possible ages of the earlier interfaces as the present data allow. Although a wide margin must naturally be left to alternative estimates, an age for the earliest occupation horizon within the limits 100,000–150,000 seems probable.

It is interesting to set this against the geological evidence for an Eemian date recently established for the closest typological homologue, the Pre-Aurignacian of the Levant[7], since the end of the Eemian according to most carbon-14-based estimates would have occurred between 55,000 and 75,000 (refs. 8*a*, *b*, 13).

Using the same gradient, an age of 38,000 would be indicated for the Mousterian–Upper Palæolithic interface at the Haua, which would compare with previous estimates for the corresponding horizon at Shanidar (Kurdistan) of 35,000–40,000 (refs. 9, 10) $\geqslant$ 32,000 at Kara Kamar (Afghanistan) (ref. 10), and $>$ 32,000 (ref. 12) (estimated 36,000, ref. 13) at Istallöskö (Hungary). On the other hand, a date $<$ 39,500 (ref. 14) is indicated by the presence of a Mousterian horizon of this age at Tabun (Palestine).

Again, the age of 14,000 indicated for the earliest Oranian at the Haua may be compared to 12,000 recently established for the middle Oranian horizon at Taforalt (Morocco)[15], whence the earliest Oranian at this site can be estimated as between 11,000 and 15,000 on the stratigraphical context.

On the basis of these figures it may be said that the chronology suggested by the combined carbon-14 readings and stratigraphy at the Haua Fteah is in general agreement with available carbon-14 dates for the corresponding cultural events in not too distant areas.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 20

CIBA FOUNDATION (at the Royal Institute of British Architects, 66 Portland Place, London, W 1), at 5 p m —Prof E Katchalski (Weizmann Institute of Science, Rehovoth) "Synthetic Macromolecules as Protein Models" (Thirteenth Ciba Foundation Lecture)

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Electrical Accidents and their Causes, including the Legal Aspects", opened by Mr S J Emerson, O B E

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S W 1), at 5 30 p m —Dr H Gysin "Triazine Herbicides, their Chemistry, Biological Properties and Mode of Action"

UNIVERSITY OF LONDON (at King's College, Strand, London, W C 2) at 5 30 p m —Dr F A E Pirani and Dr G F Elliott "Ballistic Missiles and Nuclear Weapons—Effects of Nuclear Weapons" * (Sixth of seven lectures in War Studies Further lecture on November 27)

UNIVERSITY OF LONDON (in the Gustave Tuck Theatre, University College Gower Street, London, W C 1), at 5 30 p m —Dr T Sorgenfrei (Copenhagen) "Tertiary of North-West Europe" * (Further lectures on November 21 and 23)

UNIVERSITY OF LONDON (in the Large Lecture Theatre, London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1), at 5 30 p m —Prof C R Rao (Indian Statistical Institute, Calcutta) "Some New Tests in Large-Sample Theory" * (Further lectures on November 24 and 27)

INSTITUTION OF MECHANICAL ENGINEERS, INDUSTRIAL ADMINISTRATION AND ENGINEERING PRODUCTION GROUP (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Mechanical Handling of Small Parts with special reference to Automatic Assembling Equipment"

INSTITUTE OF METAL FINISHING (at the Northampton College of Technology, St John Street, London E C 1), at 6 15 p m —Mr L E. Probert and Mr J Rollinson "Detection and Removal of Hydrogen Absorbed during Chemical and Electrochemical Processing"

Tuesday, November 21

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT AND CONTROL SECTION (at Savoy Place London W C 2), at 5 30 p m —Discussion on "The Precision Required in the Calibration of Industrial Instruments", opened by Mr P M Clifford and Mr A Felton

PARLIAMENTARY AND SCIENTIFIC COMMITTEE (in Committee Room 12, House of Commons, London, S W 1), at 5 30 p m —Meeting of the General Committee Prof P B Medawar, F R S "The Impact of Biological Research on Advances in Medical Science"

RESEARCH DEFENCE SOCIETY (in the Physiology Lecture Theatre, University College, Gower Street London, W C 1), at 5 30 p m —Sir Hugh Linstead "On Taking Account of Public Opinion" (Thirteenth Stephen Paget Memorial Lecture)

SOCIETY FOR ANALYTICAL CHEMISTRY, PHYSICAL METHODS GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W 1) at 6 30 p m —Annual General Meeting followed by the Retiring Chairman s address

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr A R Harrison "Primary Hyperparathyroidism" * (Eleventh of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 5 30 p m —Prof K R Popper "Science and the Growth of Knowledge" * (First of four Shearman Memorial Lectures Further lectures on November 23, 28 and 30)

UNIVERSITY OF LONDON (at Birkbeck College, Malet Street, London, W C 1) at 6 p m —Prof D R Cox "The Role of Statistical Methods in Science and Technology"* (Inaugural Lecture)

Tuesday, November 21—Wednesday, November 22

INSTITUTION OF GAS ENGINEERS (at Church House, Westminster, London, S W 1), at 9 30 a m on Tuesday and 9 15 a m on Wednesday —27th Autumn Research Meeting

Wednesday, November 22

ZOOLOGICAL SOCIETY OF LONDON (NUFFIELD INSTITUTE OF COMPARATIVE MEDICINE) (at the Zoological Society, Regent's Park, London N W 1) at 10 a m —Conference on "Arterial Diseases"

GEOLOGICAL SOCIETY OF LONDON (at the Royal Institution, Albemarle Street, London, W 1), at 2 p m —Symposium on "Depth and Tectonics as Factors in Regional Metamorphism"

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London Ducane Road London, W 12), at 2 p m —Prof G. H Lathe "Bile-Pigment Metabolism" *

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 2 30 p m —Miss Sylvia Crowe "Landscape and Civilization"

INSTITUTE OF FUEL (at the Royal United Service Institution, Whitehall, London S W 1) at 5 30 p m —Mr L E Reed and Mr S C Wallin "The Effect of Operating Conditions on the Performance of Different Types of Oil Burners"

INSTITUTION OF ELECTRICAL ENGINEERS, SUPPLY SECTION (at Savoy Place, London, W C 2), at 5 30 p m —Dr A S Aldred "Electronic Analogue Computer Simulation of Multi-Machine Power System Networks", Mr J G Miles "Analysis of Overall Stability of Multi-Machine Power Systems"

BRITISH INSTITUTION OF RADIO ENGINEERS, COMPUTER GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Symposium on "Adaptive Optimizing Control"

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster London, S W 1) at 6 p m —Prof E Giffen "Reflections on the Institution's Role in Engineering Education" (James Clayton Lecture)

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at 14 Belgrave Square London, S W 1) at 6 15 p m —"Food Technology in Norway". (The film and members' impressions of the 1961 tour)

UNITED STATES INFORMATION SERVICE (in the American Embassy Theatre, American Embassy (Upper Brook Street entrance), London, W 1), at 6 30 p m —Three films from the series "Planet Earth". "Research by Rockets", "Cosmic Rays" and "Radio Waves" *

BRITISH PSYCHOLOGICAL SOCIETY, MEDICAL SECTION (at the Royal Society of Medicine, 1 Wimpole Street London W 1), at 8 30 p m —Mr Murray Jackson, Mr Michael Fordham and Mr Kenneth Lambert "Jung's Later Work" (C G Jung Commemorative Meeting).

Thursday, November 23

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr J H Burns "Jeremy Bentham and University College" *

SOCIETY OF CHEMICAL INDUSTRY MICROBIOLOGY GROUP (at the Royal Society of Medicine, 1 Wimpole Street, London W 1) at 2 p m —Meeting on "Industrial Cell Culture and Vaccine Production".

ROYAL INSTITUTION OF NAVAL ARCHITECTS (at 10 Upper Belgrave Street London, S W.1) at 4 45 p m —Mr M N Parker and Mr James Dawson "Tug Propulsion Investigations"

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W 1), at 5 p m.—Prof Keith Runcom "Palæomagnetism", Prof P Allen "Palæotemperatures"

UNIVERSITY COLLEGE, LONDON (in the Physiology Theatre, Gower Street, London W C 1) at 5 p m —Dr B R Rabin "Some Aspects of Enzyme Catalysis" * (Further lecture on November 30)

UNIVERSITY OF LONDON (at the London School of Economics and Political Science, Houghton Street, London, W C 2) at 5 p m —Dr George Taylor "Britain's Botanical Power House" * (Further lecture on November 30)

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place London, W C 2) at 5 30 p m —Mr F C McLean, Mr H W Baker and Mr C H Colborn "The B B C Television Centre and Its Technical Facilities"

UNIVERSITY OF LONDON (at Queen Elizabeth College, Campden Hill Road, London, W 8) at 5 30 p m —Prof Hermann Bondi "Ideas of Special Relativity" *

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street London W C 1), at 5 30 p m —Prof I E Bush "Hormones of the Adrenal Cortex" * (Twelfth of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

UNIVERSITY OF LONDON (in the Gustave Tuck Theatre, University College Gower Street, London, W C 1), at 5 30 p m —Dr T Sorgenfrei. "Tertiary of North-West Europe" * (Last of three Special University Lectures)

INSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION CIRCLE (at Savoy Place, London, W C 2), at 6 p m —Discussion on "The 57 Effects of an Electrical Current" opened by Dr G S Brosan

UNIVERSITY OF LONDON (at Wye College, Wye, near Ashford, Kent), at 8 15 p m —Dr. H L Jensen (Denmark) "Recent Advances in Soil Microbiology" *

Friday, November 24

ASSOCIATION OF APPLIED BIOLOGISTS (joint meeting with the HORTICULTURAL EDUCATION ASSOCIATION, at the Royal Horticultural Society, Vincent Square, London, S W 1) at 10 50 a m.—Meeting on "Pests and Diseases of Ornamental Plants"

ROYAL ASTRONOMICAL SOCIETY (joint meeting with the ROYAL METEOROLOGICAL SOCIETY, at Burlington House, Piccadilly London, W 1), at 4 15 p m —Geophysical Discussion on "The Density and Composition of the Atmosphere Above 100 km ". Chairman Mr. J A Ratcliffe, F R S

UNIVERSITY OF LONDON (in the Manson Lecture Theatre, London School of Hygiene and Tropical Medicine Keppel Street London, W C 1) at 5 30 p m —Prof C R Rao (Indian Statistical Institute, Calcutta) "On Problems of Discrimination with Multiple Characters" * (Further lecture on November 27)

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square London S W 1) at 6 30 p m —Dr J R Catch "The Production of Organic Compounds Labelled with C-14 or Tritium"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 9 p m —Dr P B. Hirsch. "Seeing Atomic Defects in Metals"

Friday, November 24—Saturday, November 25

Botanical Society of the British Isles (at the Linnean Society, Burlington House, Piccadilly, London, W 1) Conference on Local Floras and Annual Exhibition Meeting

Saturday, November 25

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Mr C M Mitchell "The Folk Life of the English People" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer (preferably with an interest in theoretical or experimental plasma physics) in Physics—The Secretary, The Queen's University, Belfast, Northern Ireland (November 24)

Junior Lecturer (preferably with a registrable medical qualification) in Bacteriology—The Registrar, Trinity College, Dublin 2 (November 27)

Physics Master (graduate with a good honours degree)—The Head Master, City of Oxford High School, Oxford (November 30)

Research Fellow (with a postgraduate degree in geophysics, physics or geology, and preferably, though not necessarily, previous experience in seismological work) in Seismology—The Secretary, The University, 38 North Bailey, Durham (December 1)

Assistant Biochemist (with a degree or equivalent qualification in chemistry, with experience in, or wishing to take up, clinical biochemistry)—The Secretary, Welsh National School of Medicine (University of Wales), 34 Newport Road, Cardiff (December 2)

Lecturers in Pure Mathematics and in Applied Mathematics —The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne 1 (December 4)

Lecturer (with postgraduate experience in research coupled with a keen interest in teaching) in Physics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Hong Kong and London, December 4)

Technical Officer (with a recognized degree or National Diploma in Agriculture, and preferably experience in seed production) for Seed Multiplication—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge (December 4)

Burnett-Fletcher Chair of History and Archæology—The Secretary, The University, Aberdeen (December 9)

Lecturer (with an honours degree in electrical or electronic engineering) in the Department of Electrical Engineering—The Registrar, The University, Leeds (December 14)

Lecturer (with an honours degree in psychology) in Psychology at the University of Canterbury, Christchurch New Zealand—The Secretary Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, December 15)

Lecturer in Psychology at the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1, and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (December 20)

Lecturer (preferably with qualifications in one or more of the following fields geomorphology, biogeography, and the geography of soils) in Geography at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, December 30)

Reader in Physics—The Registrar, The University, Hull (December 31)

Mary Glendining Chair of Medicine in the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, January 15)

Chair of Veterinary Science in Massey Agricultural College (University of New Zealand), Palmerston North—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (February 1)

Computer Programmer in the Nuclear Physics Research Laboratories, to work with a research group studying high energy nuclear physics—The Registrar, The University, Liverpool, quoting Ref No CV/N/543

Lecturer (well qualified, and preferably with industrial and teaching experience) in Mathematics—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref 32/G

Lecturer (with a first degree or equivalent qualification in chemical engineering, chemistry, mathematics or physics, and preferably some industrial experience) in Chemical Engineering—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref 31/G

Master to teach Physics throughout the School, with Sixth Form and University Scholarship work—The Headmaster, King's College School, Wimbledon, London, S W 19

Postdoctoral Fellow and a Postgraduate Student in Chemistry for work on the fluorescence of aromatic hydrocarbons under the direction of Dr B Stevens—The Registrar, The University, Sheffield

Professor of Thermodynamics at the University of Malaya, Kuala Lumpur, to develop research in applied thermodynamics and to supervise courses already in existence—Department of Technical Co-operation, 26 King Street, London, S W 1, quoting MAL/861/TCS

Scientific Officer or Senior Scientific Officer (honours graduate in chemistry or biochemistry with interests in the isolation and chemistry of proteins and in studies of enzymes) in the Physiology Department—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, near Reading, quoting Ref 61/16

Senior Lecturer in Mathematics, and a Research Assistant in Mathematics—The Registrar (Department D), Bradford Institute of Technology, Bradford 7

PROGRESS IN INDUSTRY

A PAPER which was read by Mr. M Zvegintzov before Section F (Economics) at the Norwich meeting of the British Association on September 1 examined some of the accusations which have been levelled against British firms—and even whole industries—as unprogressive or backward or obsolete, in contrast to those of other countries The paper also advanced some constructive suggestions for remedying this position in so far as it can be substantiated A recent book by Michael Shanks, for example, roundly condemns the British economy as a stagnant society, and, although he may have picked out industries which are scarcely representative in regard to the proportion of employees with technical qualifications—in the example quoted it was 0 6 per cent—some of his more general charges have considerable substance Mr Shanks is by no means the first to point out that Britain should, by and large, be relying on brain-power for exports, and exporting the products which require scientific and technical skills, or even exporting her own trained man-power, rather than exporting the products of bulk production Reliance on the amateur and distrust of the specialist are admitted weaknesses, and that in too many British firms promotion comes by nepotism rather than merit is unlikely to be challenged within the reservations which Mr Shanks rightly makes, even by those indisposed to accept his view that our class system is mainly responsible for all these weaknesses

Mr Zvegintzov begins by pointing out that the man-power outlook in Britain is extremely tight, but he anticipates a useful increase in the productive age-groups by 1985, when the population is expected to reach some 56 million What he stresses more particularly, however, is the need to take steps to re-deploy continuously for new demands the limited available man-power This he regards as a *sine qua non* to avoid a halt in the rise of the standard of living The expansion of world trade, the industrialization of undeveloped countries and rising standards there and in the developed communities, all put the emphasis on a change in the character of world trade, and this assumption is more or less implicit in the recent report which attempted to forecast the long-term demand for scientific man-power

With this capacity for change must go flexibility and mobility Mr Zvegintzov is ruthless about real backwardness and unadaptability and looks unequivocably to the elimination of such firms by the process of economic competition To attempt to preserve them by protective measures or restrictive practices would be disastrous and place an unjustified strain on the limited resources of man-power in Britain, the critical problem is really how to translate the valuable craft tradition and accumulated experience which characterize a substantial proportion of the medium size or smaller firms, which constitute a significant proportion of British industry, into a modern scientific idiom The aim, as he sees it, should be to devise and supply to the craftsman the most modern and delicate tools which will enhance his craft, and this in turn involves further capital investment with saving in labour, and, even more important, educating the craftsman to demand these additions to his craft

Acceptance of this challenge by scientist and technologist as well as technician or craftsman and industrialist could well falsify some of the estimates made by the Committee on Scientific Manpower, although the question of technicians is still to be examined by it Mr Zvegintzov rightly points out that success here would go far to enable us to meet overseas competition, and that with a high craft tradition, using delicate instruments and high-precision tools for detecting, initiating and maintaining adjustments, very high standards as well as flexibility could be achieved without recourse to the further research and high expense which would be necessary for automatic production with low-grade labour Moreover, he visualizes the possibility of easy transfer of the habit of mind and inherited skill, which characterize craftsmanship, to other and perhaps new requirements as in the design and construction of scientific instruments

Perhaps the most important part of Mr Zvegintzov's paper, however, is that in which he discusses the difficulties that attend innovation in long-established and well-developed industries, and particularly in deciding where further investigation or development is likely to be most worth while It is essentially a question of how much research and where, and Mr Zvegintzov lays particular stress on the importance of effective communication between science and technology on one side, and finance and commerce on the other He visualizes, for example, a detailed cost breakdown analysis, possibly with comparisons from other countries, to bring out the features where the incidence of cost is considerable, followed by comparisons of this breakdown in a group of firms, and finally a joint study by technologists and cost-accountants to assess whether any scientific or technical innovation, or even a complete re-orientation of operations, could remove or ease this incidence of cost

In all this, close co-operation is imperative at working-level, alike between firms and between management and accountancy and the technologist, particularly if budgetary control techniques are not to confuse ends and means and impose rigid procedures which ignore circumstances and stifle initiative This kind of analysis, Mr. Zvegintzov points out, has not been tried, though departments of economics or industrial management at universities in certain industrial areas would appear to be well placed to undertake it This is possibly due to the absence of finance for this type of experimental economics, and, if so, it should be easily remedied if the Chancellor of the Exchequer's new structure is to stimulate expansion and development in industry in Britain

It is worth noting that something of this is foreshadowed in a paper which Mr G S J. White contributed in January 1960 to the *Journal of the Society of Dyers and Colourists* Limiting himself specifically to the development of dyestuffs for textiles and looking especially at the needs of the consumer, Mr White sought to assess the magnitude of the research effort which it is worth while expending on the discovery and development of new dyestuffs It is exactly this type of critical and realistic appraisal that is all-important if Britain's limited resources of trained man-power are to be deployed where they offer the greatest prospect of benefit to the national economy, and it is at this point that Mr Zvegintzov's analysis links up with the importance of effective management

It is indeed to the limitations of management, particularly in smaller firms, that Mr Zvegintzov attributes the lack of receptivity to new ideas, and he does not seem optimistic as to the possibility of overcoming such resistance otherwise than by the use of consultants This, in turn, he admits, depends on the initiative of managements if effective use is to be made of such consultants, but he sees ground for hope in the expansion of the colleges of technology and of the scientific and technological faculties at the universities Apart from its direct educational influence, this expansion offers a potential source of consultants and contacts between industry and the frontiers of science and technology, which should create a much more favourable climate of opinion in industry, and for this reason alone every effort should be made to encourage the movement of staff between industry and the universities and colleges of technology

How far the regional offices of the Department of Scientific and Industrial Research could assist in this process may be open to debate, but, from the point of view of information service alone, there seems sound sense in Mr Zvegintzov's plea that these regional offices should be strengthened and staffed with able men Moreover, there can be no doubt that the Research Associations could function very effectively here, and that their educational function, both from the point of view of information and as a source of trained staff, has been under-estimated or overlooked in the past The Robbins Committee could well give more than a passing glance at the position and functions of the Research Associations in the organization for higher education in Britain, but meanwhile the Council for Scientific and Industrial Research should examine the contribution which the Associations could make in such ways to industrial efficiency and development

Mr Zvegintzov is indeed rather more optimistic as regards the future of the smaller firms, because he believes a new generation of management is coming into office which is much more alive to scientific and technological opportunities This is the more important for, as he also contends, the rapid progress of technological co-operation and even integration in Europe may present a more important feature of the Common Market than ordinary commercial competition Here the influence of the Research Associations may be beneficial, though it is likely to be weakest in the traditional industries where it is needed most Incidentally he comments here on the need for more research in the human sciences where industry still relies far too much on guess-work, but he suggests that for the smaller and more specialized firms a powerful stimulus to co-operation could come from their suppliers of materials or equipment, and from the users of some of their products Most of these firms are bigger and with wider contacts both at home and abroad, and thus may be better placed to know what is new and promising

Whether in fact such firms may be willing to help with expert advice is a matter of opinion, and Mr Zvegintzov could be too optimistic on this point, though he suggests the possibility of joint studies under some co-operative trade association Here the Common Market could help in providing a large pool of experience, and Mr Zvegintzov in fact suggests that entry into the Common Market could provide the biggest single step for stimulating the unprogressive, though if, in fact, the operative factors are financial, the policy initiated by the Chancellor of the Exchequer at the end of July should be directed to that end Nevertheless, where the process acquires also much qualitative judgment, involving identification of needs, assessment—qualitatively and quantitatively—of advantages, and the establishment of priorities, it is more than a little doubtful how far the Exchequer is likely to be of direct assistance

The changes recently recommended by the Plowden Committee should go some way, however, to facilitate the kind of outlook that is required, and some of Mr Zvegintzov's concluding words are strikingly in line with that report Continuous progress, he believes, can only come through enterprise and boldness, which are only likely when there is confidence in the future and assurance of continuity The general climate of opinion is thus psychologically very important, and for this reason alone he condemns the current 'stop–start' policy as extremely dangerous Furthermore, the inexorable consequences of entering into scientific commitments cannot be ignored, and to insist that some co-ordination is needed between official scientific and economic organization is not to advocate rigid planning on the Russian model

Mr Zvegintzov himself leans to something on the lines of the French system of the Commissariat aux Plans, attached to the Prime Minister's Office, but he insists that above all development must come from within industry itself There is no substitute for efficient self-management, and probably the wisest national policy for Britain is one that provides definite encouragement to the enterprising and efficient, removing obstacles and providing positive advice and even help, rather than one that attempts to stimulate the backward or unprogressive

Much of Mr Zvegintzov's argument, it is true, can be traced in Sir Harry Pilkington's Fawley Lecture of three years ago, "Facing the Future in Industry" Sir Harry made the vital points about effective leadership, the choice of priorities, particularly in regard to the direction of research, and the real co-ordination of research, technical development and production, but it is hard to point to substantial progress in many sectors of industry since that Lecture was given Nor does Mr Zvegintzov himself really face some of the issues that can arise in such an industry as shipbuilding or the machine tool industry, if the industry itself really fails for internal reasons to meet the challenge Is the Government to stand idly by if employers fail to seize their opportunities and make the necessary adjustments, or if trade unions cling to obsolete and restrictive practices that prevent full advantage being taken of technical advance ?

It would be foolish to pretend that Sir Harry Pilkington, Mr Zvegintzov or Mr Shanks has provided the answer to these problems, nor is it probable that they would claim to have done so They have indicated certain aspects of the problem which call imperatively for further and urgent examination and for some clear and constructive thinking There are matters which the Minister for Science as well as the Chancellor of the Exchequer and their advisers should be examining, and there are others to which the Minister of Education should be giving attention But the major challenge is to industry itself, and to its co-operative organizations, both of employers and trade unions The situation is far too serious for either management or labour to rest content with putting the blame on others even for admitted mistakes The need for efficient management is once again overwhelmingly demonstrated, with all that that implies regarding training and selection for management No less clearly, however, is demonstrated the need for thinking about production in terms of the techniques and possibilities of to-day, and not in terms of practices of a previous century, and in that the trade unions have at least as large a responsibility as that of management

The primary emphasis, moreover, must be on flexibility, imagination and information On information, because it is only the free dissemination of information that prevents the duplication of effort which is so wasteful of resources—material and man-power—and provides the basis for sound judgment as to the objectives most worth while in research or in development That reason justifies the Committee of Public Accounts in pressing for more informative accounts from the Atomic Energy Authority, and the relevant passage in the Committee's Third Report for the Session 1960–61 * should not pass unnoticed The Committee fully appreciated that it is necessary on security grounds to restrict the information provided by the Authority's published accounts, but although the Public Accounts Committee was concerned in this instance more particularly with the control of recoverable expenditure relating to reactor research and development, and the manufacture and sale of fuel elements, it is clear that it is not satisfied that sufficient information is disclosed as to the Authority's expenditure on research and its distribution

Imagination is necessary, because on this factor depends very considerably the ability of Great Britain to exploit some of the possibilities of new techniques in automation and the electronic computer Some of these possibilities were indicated by Dr B V Bowden in his evening discourse, "The Impact of Automation", before the British Association at Norwich, when he hinted at possibilities of their use by the Exchequer in economic controls The importance of imagination both in the use of such techniques and in training a generation of scientists competent to use them was particularly well stressed by Prof R Courant in an address last year at the closing session of an international symposium arranged by the International Computation Centre in Rome and which has now been published in *Impact*

Flexibility is also essential, because of the demands for adjustment and a new outlook which it makes at all levels There is the demand on education to provide men and women with minds alert to the new possibilities and equipped to use the new opportunities There is the demand on management with which Mr Zvegintzov dealt, which involves not merely facing present-day problems of development but also foreseeing the human and technical problems involved in expansion, in automation and in redundancy, and in the recruitment of managers competent to deal with these problems in the future There is the demand made on manager and trade unionist alike to face these problems as they arise, and to adjust practices to new needs, developing habits of co-operation rather than restriction, and preparing for change rather than shrinking from it or ignoring it Solutions to these interlocked problems will not be found in isolation, nor can the necessary policies be implemented without mutual understanding and co-operation, and the task of creating in industry and in Britain generally the appropriate climate of opinion is one to which all possible efforts should already be directed

COSMIC RADIO WAVES

Cosmic Radio Waves

By I S Shklovsky. Translated by Richard B. Rodman and Carlos M. Varsavsky Pp xvi+444. (Cambridge, Mass Harvard University Press; London Oxford University Press, 1960) 65*s* net.

THOSE of us who were fortunate enough to receive a copy of Shklovsky's book when it was first published in Moscow in 1956 realized that a significant contribution had been made to radio astronomy by this Russian scientist Now the value of the book, and the understanding of Shklovsky's personal contribution, has been greatly increased by the appearance of this English translation The author has himself revised the work to bring it up to date so far as the contributions to radio astronomy which were presented at the Paris Symposium in 1958 Even so, in view of the tremendous growth of the subject and the productive research of the world's major radio telescopes since that date, it might be expected that the book would already be too old to be useful In fact, the book makes vivid reading and will be an inspiration to all concerned with the problem of radio waves from the cosmos.

---

* Third Report from the Committee of Public Accounts, Session 1960–61 Pp 40 (London H M S O , 1961) 2*s* net

The main reason for this timeless quality of the work is to be found in the great theoretical contribution which Shklovsky has himself made to radio astronomy About ten years ago radio astronomers in the West were under the influence of the radio star idea as an explanation of the origin of the radio waves from the local galaxy, by which a distribution of radio sources somewhat similar to that of the common stars was believed to be the probable origin of the galactic radio emissions. Shklovsky held that this view was untenable He believed that the main generally distributed radio waves from the galaxy had two separate origins, first, a 'flat' component closely concentrated in the plane of the Milky Way arising as an emission with thermal characteristics from the free-free transitions in the ionized hydrogen gas in the plane of the galaxy, second a 'corona' or 'halo' component, surrounding and enclosing the galactic system of stars and arising as synchrotron radiation from relativistic electrons moving in the interstellar magnetic field He believed that a few of the intense discrete radio sources of emission were supernovæ remnants lying in the plane of the galaxy (as exemplified by the already well-known case of the Crab nebula in Taurus), and that the majority were extragalactic.

At first Shklovsky's views received little attention, but during the past few years there has been clear observational proof that they provide a reasonable explanation of the emission both from the local galaxy and from the individual extragalactic nebulæ Shklovsky's explanation in this book of the analytical procedure by which he arrived at these conclusions from a study of the spectra and isophotes of the radio emission made by radio telescopes which confused the issue by their poor resolving power is a masterly example of scientific procedure which should be studied by all young research workers

Another long section of the book which deals with the emission of light and radio waves from the supernovæ remnants still further exemplifies the fruitfulness of the conceptions of Shklovsky and his Russian colleagues The discovery of the polarization of the light from the Crab nebula, and (since the book was revised) of the polarization of centimetre radio waves from the nebula, provides firm observational support for these ideas that the emission arises as synchrotron radiation from the motion of high-speed electrons in the magnetic field of the nebula In due course these electrons move away from the nebula to form the electrons in the corona of the galaxy and to become, with other energetic particles resulting from the explosion, the primary particles of cosmic rays.

The scope of the book is specifically limited to the problem of the cosmic radio waves of galactic or extragalactic origin. The radio or radar astronomical aspects of the subject concerned with the solar system are excluded For all who are interested in the cosmos this book makes exciting reading, while for astronomers of all kinds and for those physicists who are concerned with the problem of the origin of cosmic rays the book will be an invaluable acquisition

BERNARD LOVELL

THÉODORE SCHWANN

Lettres de Théodore Schwann (1810–1882)

Éditées et annotées par Prof Marcel Florkin. Pp 274 (Liège Société Royal des Sciences de Liège, Université de Liège, 1961) 250 francs

THE 'cell-theory' is the story of the recognition of the cell as the essential unit in the structure and function of the body. The first suggestion of this coming change occurred in the work, *Die Zeugung*, which Lorenz Oken produced in 1805, but the important dates are 1838 and 1839, when Matthias Jacob Schleiden (1804–81) and Theodore Schwann (1810–82) enunciated in clear form the new ideas

In the volume reviewed here a distinguished Liège professor and medical historian shows how the second of these two men, who was born at Neuss-am-Rhein, apparently failed to justify the high hopes of his earlier years He had shown great promise when he was working in the laboratory of Prof Johannes Muller in Berlin but in 1839 he became a teacher in Louvain and afterwards in Liège, and in Belgium he published nothing but a few unimportant treatises and a brochure accompanying the apparatus which enabled one to exist in an irrespirable medium, it was shown in the Universal Exhibition in Paris in 1878

F G J Henle (1809–85) said that Schwann, during his five productive years, did enough for science to justify the entire lifetime of a great man He also noted that Schwann had been forced to lose much time studying systematic human anatomy when his real forte was physiology, and, moreover, when the disputes about general anatomy were repugnant to his sensitive nature.

At Louvain and at Liège the Roman Catholic Church was not concerned with the matter, for only at the end of his life did Schwann become a devotee to the faith, and he was unhampered in both his ideology and his religious experience

In 1842 at Louvain he began an intimate diary or *Tagebuch innerer Ereignisse*, part of which was published in 1936 An unpublished part, of exceptional autobiographical interest, was produced by Florkin in 1951, and there is also a series of treatises by Schwann relating to his inner life

Three periods can be distinguished in his story, namely, an ethical one, during which he strove for knowledge and the perfecting of self, a scientific one, which was rational and Promethean, and a mystical or metaphysical one, all three being characterized by intellectual eagerness Schwann's contemporaries and the generations separating us from him knew only his scientific output, considering it an intellectual oasis in the general drabness of a life devoid of eminence They were unaware that behind the decorous existence of the famous and conscientious but unproductive faculty professor was being carried on an unceasing intellectual struggle

Florkin enlarges on these three periods In the first he has much to recall about one Wilhelm Smets, in the second he recaptures the liberal Berlin atmosphere dominated by the powerful personality of Johannes Muller, and Schwann's attempts to make biology a province of physics In an appendix to his *exposé* of his cell-theory, Schwann disclosed a philosophy which rejected vitalism and sought the final cause of the universe in the actual properties of atoms. He affirmed the physico-chemical nature of life, this affirmation being his crowning achievement as a scientist, taking him away from scientific inquiry and orienting him towards metaphysics It was at this period in 1838, in the course of an attack of conscience, that he renounced rationalism and the scientific method in an attempt to know his Creator and thereby truth.

Florkin forecasts that Schwann's personality will certainly stimulate various works, not only by historians of science but also by psychologists given to the 'characterology' of the scientific investigator and to that of the meanderings of the spirit of man

Besides renewing biology by his discoveries and scientific theories, Schwann's philosophic and religious pre-occupations, and the transfiguration of science into religious emotion which he sought in his theories, the intensity of his inner life and his long resistance to orthodoxy outline a life at once sad and serene, untiringly devoted to the most exalted and moving aspirations of the human soul. As Edmond Scherer said of another great and lonely figure, Frédéric Amiel, Schwann was "de ceux qu'a touché de son aile l'ange des visions ineffables et des divines tristesses"

KENNETH J FRANKLIN

WEALTH OF THE FOREST

Les Plantes Utiles du Gabon

Essai d'Inventaire et de Concordance des noms Vernaculaires et Scientifiques des Plantes Spontanées et Introduites Description des Espèces, Propriétés, Utilisations Économiques, Ethnographiques et Artistiques Par André Raponda-Walker et Roger Sillans (Encyclopédie Biologique, Tome 56) Pp x + 614 + 53 planches (Paris Éditions Paul Lechevalier, 1961) 250 NF

TO us who depend increasingly on 'supermarket' and slot-machine, one of the most interesting aspects of life in less sophisticated lands is the wide use made of local plants to supply daily needs Nearly every plant seems to have its use; this one as a cure for fever, the next providing fibre for fish-nets, a third giving wood for musical instruments Of interest, therefore, is a new book describing useful plants of that western part of equatorial Africa known as Gabon Dr Albert Schweitzer's reference to this coast as the edge of the primeval forest comes to mind, and, although the vegetation of the coastal and riverine areas is now well known and is much altered by man's activities, the vast area of the interior, mainly forest, remains inadequately recorded

In a pleasant foreword by Prof Trochain, the book is described as the joint product of a priest-botanist-ethnologist and a botanist-draughtsman-artist During thirty years of missionary work in that country, the senior author, the Abbé Raponda-Walker, amassed the information on plants and their local names and uses which forms the bulk of the text The notes being placed in the hands of R Sillans, he attempted, as is explained, to bring the material to life, to depict the vegetation of the region as known to the inhabitants and as it enters into their daily life

The result is a book which is full of information for both botanist and ethnologist It opens with short introductory chapters on the history of botanical exploration in Gabon, on the climate and types of vegetation, and the vegetable products entering trade In the main part of the book, the plants which are put to use are described in turn, the genera being arranged alphabetically in their families. For each species is given a short description, a note of its use in native custom, and a list of vernacular names by which the plant is known among various of the 27 tribes in the country The artist provides 52 full-page botanical drawings of important species In addition, the text is enlivened by figures and illustrative sketches If the writer tells us that wood of *Alstonia* is used for ceremonial masks, the artist employs his pen to show the masks worn by some tribal society in their fetish rituals The book is well indexed, and nearly 8,000 entries in the index of vernacular names are a measure of the Abbé Raponda-Walker's diligent observation

Many plants described here are common also to forest country of West Africa to the north-west, and it is possible to compare the uses of them in Gabon with those so well described earlier by Dalziel, or in Irvine's *Woody Plants of Ghana* (see p 695 of this issue) Others again are peculiar to the region of Gabon, ranging in economic importance from the great okoumé tree, *Aucoumea klaineana*, the timber of which constitutes the greatest wealth of Gabon to so small and nasty a plant as *Ataenidia* of the arrowroot family, the leaves of which, thrown into the cooking-pot, cause discord in the household or village Ferns are among the plants of which use is made, and an unusual record is the weaving of the black shining rhizomorphs of a fungus into ornamental cords to wear on the body An appendix gives the vernacular names of recognized cultivars of some staple crops, including banana, cassava, and sugar-cane

The useful plants of Gabon, as here presented, include many introduced plants Some, like banana and maize, have long been adopted by the Gabonese and have become part of their life. Others have not penetrated farther than the trial-ground or mission-garden, and, although mention of this is made, their appearance at all in the main text as useful plants of Gabon may well be questioned To find included the Judas tree, *Cercis siliquatrum*, a Mediterranean plant ill-suited to the humid tropics, is as unexpected as it may be misleading But this, and the mis-spelling of some botanical names, are minor blemishes in a work which contains much of value and of charm

T A. RUSSELL

FORMAL LOGIC IN RETROSPECT

A History of Formal Logic

By Dr I M Bochénski Translated and edited by Ivo Thomas Pp xxii + 567 (Notre Dame, Indiana University of Notre Dame Press, 1961) 20 dollars

IN this monumental work, Prof Bochénski presents us with the results of some forty years of research Scholars are already aware of the merits of the German edition, published in 1956, especially the accuracy of the transcripts from Aristotelian texts Now we are enabled to have the outcome of this 'labour of love' in English, thanks to the University of Notre Dame Press, and a competent translator In the event, these pages are very much more than a source-book They will be consulted by logicians and historians for many a generation maybe, before anything comparable appears again The decimal system of entries—both extracts and commentaries—of the original is maintained with trifling exceptions, which makes reference easy within the volume itself, and to the German version

An introduction to the present edition has been added, which has as its main object the slightly unusual one of augmenting the very brief (and perhaps inadequate) treatment of Abelard in the original. It is good to have this, though one would have thought that a more appropriate place could have been found for it. But we are left in no doubt that formal logic was well away in its scholastic form by the twelfth century.

In his own introduction, the author says plainly what he conceives his task to be, and how he intends to carry it out. Logic did not develop continuously, rather it started at various places and at various times almost independently. But, characteristically, men soon found that they were grappling with much the same essential problems, approaching them by different paths. This concept sets the pattern for the whole book. Thus we have ancient logic, scholastic logic, mathematical logic, and Indian logic. The somewhat arid period of 'classical' logic is briefly reviewed. Before discussing these sections in greater detail, it is clear that two figures stand out in bold relief, Aristotle and Frege, the rest grouped around them with the symmetry of an artist. It is almost as if Prof. Bochénski had painted a new version of Raphael's great picture, adapting the stance of the figures to subsequent history as the grand drama of the pursuit of reason unfolds.

Ancient logic (Part 2) shows the author at his best, and text is superb. Here is the essence of the esoteric syllogism, displayed both in its intellectual power and its æsthetic appeal. Aristotle scarcely achieved corresponding success with modal syllogistics, and that probably explains why Prof. Bochénski gives this subject relatively little attention. The criterion throughout is that of quality, and the extent to which original minds have been able to approach perfection of presentation and methodological rigour. Included in this section are, of course, the Stoics and the Megarians, together with a host of commentators. It is good to read such a vivid extract from the tree of Porphyry, with its focus on extension and intension, and the principles of classification. This was not an epoch of discovery, but the literature is valuable and its synthetic character important. Theophrastus, pupil and successor of Aristotle, receives more than honourable mention. In addition to his logic, we salute him as a pioneer in meteorology.

Scholastic logic (Part 3) will be welcomed not only by logicians but also by medievalists. Naturally, there is a good deal here that stems from the Stoics and the Megarians. But imperfect as our knowledge of this period may be, it is one of supreme consequence since in fact such giants as Albertus Magnus and St. Thomas Aquinas brought to Aristotelianism not only a new life but also gave mankind something to live for, and thus realized, for the time being in any event, the concept of philosophy as the serving-maid of theology. This is not what is said in so many words, but the author's mastery of his material is such as to commend his scholarship to students of subjects sharing boundaries with those of formal logic.

Part 4 (classical logic) has already been mentioned. With Part 5 (mathematical logic) we are brought right up to 1931, with Godel's famous theorem, announced in that year. The highlights here, as one would expect, are the works of Boole, Schröder, Frege, Whitehead and Russell.

Indian logic (Part 6) forms a survey of a branch of learning all too little understood in the West. Prof. Bochénski makes a point to the effect that had India produced a Plato or an Aristotle at the appropriate point in history, a long stretch of time would have been saved in the working out of principles. But this was not to be. Seen against the background of centuries, creative genius acts somewhat like a modern computer, solving almost in an instant of time some problem previously wholly intractable.

The bibliography is extensive, running to several thousand entries. It has, for reasons of economy, been photocopied from the German, a sensible plan which will hurt nobody. In addition, are a series of indexes, dealing with names, subjects and signs.

There has been nothing like this book before. It is far from easy reading, but the planning is itself so logical, and the commentaries themselves so apt, that one is left with the impression of a veritable masterpiece, set off by a frame and background at once wholly sympathetic and comely.

FUNCTION THEORY AND ITS APPLICATIONS

Lectures on the Theory of Functions of a Complex Variable

By Prof. G. Sansone and Dr. Johan Gerretsen. Vol. 1: Holomorphic Functions. Pp. xvi+488. (Groningen: P. Noordhoff, Ltd., 1960.) 45 D. fl., 12 dollars, paper bound; 48.75 D. fl., 13 dollars, cloth bound.

Modern mathematics is in the process of becoming more and more abstract. We are in general less interested in numbers than in spaces of objects having certain properties. However, this process of abstraction necessarily moves more slowly in disciplines with physical applications.

It is for this reason that Sansone and Gerretsen's *Lectures on the Theory of Functions of a Complex Variable*, although a little old-fashioned, is bound to make a lot of friends, particularly among those who wish to learn function theory in order to use it. The authors claim to address those interested in advanced methods of analysis. They rather quickly cover the foundations, including Cauchy's theorem, and concentrate on what one can do once the basic theorems are proved. There is, however, a fair amount of theoretical stuff such as, for example, the Vitali convergence theorem, the Borel–Caratheodory inequality and the theory of integral functions of finite order. Picard's theorem for functions of infinite order and subharmonic functions are not covered. Conformal mapping, both theoretical and practical, is left for a second volume.

Among the practical topics which are covered are the inversion of power series, theta, elliptic, gamma, Legendre and the Riemann zeta functions, Laplace integral, Dirichlet series, as well as some other special functions but not Bessel functions.

The many applications include the Euler–Maclaurin and Poisson summation formulæ, and the analytic proof of the prime number theorem, asymptotic expansions of various kinds, use of the Bernoulli numbers, summability of power series, by the methods of Borel and Mittag-Leffler, and special series of many kinds, including one for Euler's constant.

The book should be very valuable to anybody who is interested in function theory, mainly in order to use it. The English is nearly always good. The term "monotonously increasing functions" should appeal to many students.

W. K. Hayman

Woody Plants of Ghana with special reference to Their Uses

By R F Irvine Pp xcv + 868 + 34 plates (London Oxford University Press, 1961) 105*s* net.

THIS beautifully produced book, illustrated by 142 full-page line drawings and 34 plates, is primarily concerned with the useful properties of Ghana's trees and shrubs It incorporates much of the material in Dalziel's *Useful Plants of West Tropical Africa*, and supplements it with Dr Irvine's own extensive knowledge of this subject There is a wealth of fascinating information on economic products and medicinal properties, both factual and fancied, for the 'doctrine of signatures' is implicit in much of African medicine This is ably supported by a comprehensive series of indexes and glossaries, and by an extensive collection of vernacular names

The purely botanical part of the book is less happily conceived Each species is accompanied by a short botanical description, but this is quite inadequate to enable the species to be identified and there are no keys, while the errors in nomenclature are numerous The citation of individual specimens seems unnecessary in a book which is not primarily a taxonomic work, and it is surely pointless to cite unnamed species known only from incomplete specimens when they have no known uses

It is understood that this volume is to be followed by another on the herbs of Ghana It is suggested that much of the botanical detail might profitably be omitted, leaving the author free to concentrate on the useful properties where he is clearly an expert, and enabling the publishers to offer the book at a cheaper price W D CLAYTON

Re-educative Treatment of Suppression Amblyopia

Being an abridged English version of Jean Sédan's "Post Cure de l'Amblyope Rééduqué" By T Keith Lyle, Cynthia Douthwaite and Jill Wilkinson Pp xii + 135 (Edinburgh and London E and S Livingstone, Ltd , 1960) 25*s* net

THIS is an English version of Dr Jean Sédan's well-known compilation of test types and pictorial exercises designed for use in the treatment of amblyopia associated with uniocular strabismus. Dr. Keith Lyle, who was responsible for the preparation of this version, states in his preface that he has found Sédan's methods of the greatest value in the work of the Orthoptic Department at Moorfields Eye Hospital, London.

Three types of exercise are represented In the first, the patient is required to detect misprints in test passages in a variety of sizes of print In the second, he has to solve simple problems or detect errors in exercises presented in numerical, diagrammatic or pictorial form (Some of the pictures are delightfully French) In the third, there is a number of special exercises intended for patients with eccentric fixation or related disturbance of spatial localization.

It is unfortunate, perhaps, that no evidence as to the efficacy of these procedures is presented None the less, Sédan's methods would seem very well worthy of trial in the treatment of squint and related conditions in which systematic eye-exercises are prescribed Some of his material too, might find useful application in the study of other types of visual disorder, in particular the defects of perception which may result from injury or disease of the brain.

O. L ZANGWILL

Inductive Probability

By John Patrick Day. (International Library of Philosophy and Scientific Method) Pp xvi + 336 (London Routledge and Kegan Paul, Ltd., New York The Humanities Press, 1961) 40*s* net.

THE author of this book has performed a most valuable service This consists essentially in treating his subject philosophically rather than in the more 'restricted' sense as an essay in logic. That little mathematical knowledge is required of the reader is neither here nor there the approach is not esoteric Probability as a concept is used by many professional people, but even ordinary mortals use it quite widely Much the same can be said of evidence The writer comments on the advantages and disadvantages of the jury system on balance, it comes out on the right side, in spite of the fact that sheer quantity of evidential material is a strain on the layman This is only another example of our national inclination to keep the expert in his place

The scheme of the present volume comprises a full discussion of inductive probability, subject–predicate formulæ, functional formulæ and determinants, theory of elimination, inductive reasoning and inductive logic In spite of a commendable determination to write clearly, the author seems occasionally to share with no less a person than John Ruskin a tendency to make meanings obscure by over-emphasis on detail Also, his use of the word 'generally' (for example, on pp 51, 58, 72) is not altogether happy, supposedly he means 'usually'

All in all, scientists would do well to read this book carefully, both for its meticulous scholarship and for its discipline Their weighing up of what is true and what is likely to be true will be greatly helped, with corresponding confidence in their conclusions F I G RAWLINS

Crystallization

By Dr. J W Mullin Pp ix + 268 (London · Butterworth and Co (Publishers), Ltd , 1961) 60*s*

THE first half of this book surveys ably, with much detail. the physical chemistry, properties and phase equilibria of crystals and solutions with some reference also to melts The final chapter summarizes in useful fashion the techniques and problems of sizing and size analyses In between we have a chapter summarizing briefly the better-known theories of the mechanisms of nucleation and crystal growth It would be a superhuman task to render the literature on these topics into a single, readable chapter and the author might well have condensed his material yet more without loss As it stands, however, it is slightly incongruous to find 103 papers, presented at three symposia, dismissed in a single reference as "able summaries", while an almost irrelevant reference to gas absorption merits a whole paragraph and the beard of the late W H. Perkin a whole sentence

It is particularly significant that the remaining chapters, treating re-crystallization, industrial crystallization and equipment, are wholly qualitative. This characterizes the status of crystallization as a unit operation. Due to the difficulties involved and perhaps to the guarding of technical secrets, almost no quantitative investigations of the process have been published The real utility of this book depends to a large extent, therefore, on engineering design data being made available for the process chemists and chemical engineers for whom it is intended

S H. BRANSOM

THE INSPIRATION OF SCIENCE*

By Sir GEORGE THOMSON, F.R.S.

Master of Corpus Christi College, Cambridge

WE are all well accustomed to science as the basis of technology, the source of the fundamental knowledge which it is our duty to apply to the service of man, but there is a quite different side to it and one not less in importance, that is science as truth, or at least one of the great aspects of truth, science as a human value—something which exists for itself and is self-justified as is music or painting, or indeed the human relations. This side should be an inspiration to all who are concerned with science in whatever form. Surely we have reason to be proud that such an insignificant creature as man should even be aware of his own insignificance? That he should be able to reckon up the countless billions of stars in the Galaxy and of galaxies in the universe and understand something of how they are made, that he should be able to measure the atoms and to determine their structure, that he should be able to understand even a little of the astonishing meaningful complexity that goes to make life? But besides its emotional appeal science is the philosophy of our age, and we who practise it should spend a little time in thinking of it from this point of view and seeing in what ways it differs from some of the older philosophies.

First of all physics relates to the outside world; it requires that a consensus of opinion be possible between different observers, or in other words that the observations made by different people can be adjusted so as to be consistent with a rational theory. One need not go into the complications of relativity, it is enough merely to consider the different judgments of relative position which two people sitting in an ordinary room will make and which are, normally at least, consistent with the furniture and the room being rigid objects and with light going in straight lines. It is in fact precisely this which is the justification for believing in an outside world: the fact that one can describe it in a way that can be accepted by all observers. Compare this outside world with the private world which each conscious person carries about with him. In this private world are dreams, emotions, pain and so on, things which he may be able to explain by symbols to his fellow men but for which, in the last resort, they must take his word and which they cannot directly share.

Physics, like other sciences, is based on concepts which have names, things such as mass, temperature, energy, rays of light, electrons and so on. It is these concepts which determine the stage to which physics has arrived because they determine what statements can in fact be made, and major advances in physics are, to a great extent, discoveries of the right concepts.

Concepts are usually suggested by experiments, but they seldom remain directly tied to them, at least not to simple experiments. Temperature is a good example. Starting from sensations of warm and cold, which (in so far as they measure anything) measure a rather complicated mixture of the temperature and conductivity of the substance in contact with the skin, temperature was early measured by the expansion of solids and liquids. These expansions are not uniform, and the scale of temperature derived from one body is near to but not identical with that derived from another. If temperature is to be a fundamental concept it must be removed from this dependence on the particular substance. It is well known how this has been done, by making it dependent on the ideal efficiency of certain heat engines, but this is not, of course, the way that anybody ever actually measures it.

Much the same kind of thing happens with space, spacial measurements, and most of geometry, depend on the assumption of rigid bodies to act as measuring rods or theodolites. There are no rigid bodies, but it is possible to make satisfactory corrections for the lack of rigidity of the nearly rigid ones. Some concepts are even less closely connected to experiments than these: for example, that of molecular chaos. It was a long time before this could be directly observed, yet the idea was most valuable to physics. The same is true to an even greater extent of the concept of atoms, and one of the lessons of the history of science is that one should beware of the purism which demands very close connexion between a concept and what is at the moment experimentally verifiable. One of the most interesting things in theoretical physics is the way in which certain concepts develop a usefulness far beyond that for which they were originally intended. Atoms are a case in point—so are quanta which, starting from a theory of black-body radiation, are now fundamental to all physics.

But not all concepts conform exactly to Nature, they are approximations, but they are not to be despised on this account. Take, for example, rays of light; they are still more important in practical applications of optics than are waves or quanta, although even in the time of Newton it was known that they were not the whole story. Another example is the use in physics of the concept of a surface as a mathematical discontinuity between two bodies, for example, solid and gaseous. There is no such thing as a surface in this sense, speaking strictly, and it is certainly not mathematically smooth. Atoms do not have sharp edges, there are vague regions round them in which they exert force, yet the concept of a surface is of immense value not merely to engineers but also to most of classical physics. Some concepts are absorbed by others, or perhaps one should say become tributary to them, for they still continue to be used, as the concept of mass has to that of energy.

There has been much discussion as to the 'reality' of certain concepts, for example of the electron. I think sometimes this fails to realize how artificial are the concepts of ordinary life, of common-sense things. Few people think it necessary to justify the idea of a chair or to ask whether it is real, yet it is in fact a most complicated idea. It is derived from a variety of different impressions, visual and factual, and is defined partly by appearance and partly use. A chair seen by the engineer is a collection of stressed material; seen by the botanist, if it is wooden, a collection of plant cells; seen by the housewife, something on which people can sit. While electrons are countable so that in any given circumstances they are a whole number, in a group of chairs there may be some broken ones of which it is doubtful whether they rank as chairs or not. The chair is really a very vague idea, and if one must argue about reality (which perhaps should be considered a bad word) the electron's claims are, I would say, better than the chair's.

---

* Substance of the first Thomson Lecture of the Society of Instrument Technology, delivered on October 19.

Concepts are used to form hypotheses, theories, and laws which are statements of varying certainty about concepts. It seems to me that the differences between these words lie more in the emotional attitude of the user than in anything else. A law is some statement about concepts in which you really believe, a hypothesis is one about which you choose to remain uncertain. I will just use the middle word 'theories', the emotional content of which is somewhere between the two. All physics is based on experiment ultimately, and on the idea that experiments can in some way be repeated. By experiment I do not necessarily mean something in a laboratory, but merely something that can be observed; for this purpose the explosion of a supernova is an experiment. The first point that I want to make is that one cannot repeat an experiment unless one has some sort of theory, because repeating an experiment implies that the conditions are the same on the two occasions. Now all the conditions are never the same: life moves on, the planets are in different positions, the apparatus is either made of the same bits of material (in which case it has been worn) or is made of different material, in which case how do you know it is effectively the same? The answer is, of course, to say that the relevant conditions must be the same if you wish to repeat an experiment. But who is to say which conditions are relevant and which are not? This can only be done by a theory. The theory need not be a detailed one, it may merely say 'I believe that all that matters for the experiment I am now going to perform is the state of the objects on this table' and this may well be true if you make some allowances for the gravitational direction of Earth. But your experiment may go badly wrong if someone is making electrical disturbances in the next room. The theory must be sufficiently wide to give you an idea as to what matters.

Dr. K. Popper has made the very good point that theories in science exist to be disproved; they can never be proved. Since they are general statements that something will always occur, one can never be certain that a case of exception will not occur; if it does occur the theory is disproved and is either abandoned or, if it has shown previous merits, is somehow altered to fit the new evidence. The great strength of science as compared with philosophy is that theories can be disproved or at least shown as inadequate and that this can be done in a manner which compels the assent of all, or almost all, reasonable people; in short, that a consensus of opinion is possible and one which appears to be lasting. This consensus, philosophy never seems to have achieved, or at least only for short periods.

Personally, I think that the existence of technology is an enormous support to theoretical physics in this way. It is impossible not to believe in the validity of theories which enable complicated machines like television sets to be made and operated by people who are wholly ignorant of the scientific principles which we scientists say they depend on. It seems to me psychologically impossible not to believe that such principles have, in fact, a validity external to our minds. It is not necessary for this purpose that the principles are absolutely true or extend over all conditions: it is possible that Maxwell's equations do not apply in the interior of an atomic nucleus, but this does not detract from their validity for television.

Of course, the prestige of a theory goes up enormously if it can predict the unexpected, and rightly so. The mere fact that a theory covers known experiments counts for very little; after all, it is possible to draw curves through any finite number of points in an infinite number of ways, no one of which is in principle better than another. Experiments can always be represented by empirical formulæ which need have no further validity whatever. A theory must be æsthetically satisfying as well as fit the facts. This is equivalent to saying that Nature in some way respects our æsthetic judgment. In a sense I think it does, but this is very largely because our judgments of what is an æsthetically acceptable theory are based on our experiments on theories of the past which have been successful. In other words, we are assuming that Nature is somehow of a piece, and that we can hope to recognize theories which conform to the pattern just as one might hope to recognize somebody's handwriting in a few words though one has never seen those actual words written by him before. I am not sure whether this implies a personification of Nature or whether it is a consequence of the way our brains work.

A good analogy of the relation between physical theories and external realities is given by an ordinary map of Earth's surface. Like the map, the theory is either something on paper or in the mind of the physicist, just as the map may be in the mind of the traveller. The concepts of physics correspond to the signs on the maps denoting rivers, roads and the like. The making of such a map consists in translating Nature on to a piece of paper, and the use of the map involves reversing this process, reading the map, deciding, that is to say, that one particular point on the map is the place where you are standing, that the hill on your right is represented by a certain group of concentric contour lines on the map and so on. All theories are approximate in practical application, ignoring small effects; just so, all maps leave out details. They may show hills and slopes but they will not show molehills. This, however, does not prevent them from being useful. Again, every map of Earth on a flat piece of paper is necessarily distorted since you cannot bend a plane to fit a sphere. Several kinds of maps are possible corresponding to the different methods of projection; some are more suitable for one purpose, some for another, but there is none which is universally the best. Yet a map can be right or wrong; a map which shows Piccadilly Circus north of Oxford Street or Birmingham in the middle of Spain is definitely erroneous.

This applies to scientific theories. They can be so badly wrong as to be useless. They can never hope to be completely right, with the rarest and doubtful exceptions. Two quite different theories may be equally valid: compare for example, the thermodynamics and the kinetic theory approach to the properties of gases; they start from wholly different ideas yet arrive at practically the same conclusions, but for some purposes one is better than the other.

The great authority of Lord Kelvin is often quoted to extol the importance of the quantitative, which implies measurement, in physics. He was, of course, right in urging its importance; but it should, I think, always be remembered that in the last resort we are trying to do something qualitative. The pure scientist is aiming at producing a theory which will be convincing and satisfactory, which will make people feel that they understand, and which will predict something new and exciting. The object of the applied physicist or engineer is also in essence qualitative. For example, if he is designing aeroplanes the question of top speed is very important and it can be measured. But speed, predicted or measured, is important because of its qualitative implications. You desire an aeroplane which will get you to your destination before your friends are tired of waiting for you, or if it is for war, one which will return safely from its sortie having shot down the enemy. The quantitative predictions, important as they are, are really the means to the end, not the end itself.

I have spoken of a good theory being æsthetically satisfying because as we have seen a mere empirical formula is hopeless. Comparatively little has been written on the æsthetic side of science apart from mathematics. Some of the same criteria apply here as do there: for example, the theory must be general, simple and striking. It should not involve arbitrary constants or functions, unless indeed it can be shown that the constants which are introduced are related to something quite outside the theory itself: for example, Maxwell's equations and the velocity of light. But I am inclined to think that the most important feature in making one accept a new theory is what I have already said, its general resemblance to the successful theories of the past.

The quantum theory has made, as we are all aware, an alteration of immense importance in our ideas of physics. It has replaced determinism by probability. The uncertainty principle of Heisenberg is, I think, the first occasion on which science has laid down limits to knowledge as opposed to the familiar limits to what man can perform given by such principles as the laws of thermodynamics. It means an alteration in the sense in which Nature is rational. One cannot predict certainties, one can only predict probabilities and it becomes a matter of some difficulty to know what is meant by a probability when you deal with a unique event, an event which cannot be repeated—for example because the apparatus is changed or broken and is too complicated to re-make. I am thinking in particular of experiments on brains, animal or human. In more ordinary laboratory experiments one can use an apparatus or series of apparatus, each of which conforms to the same theory. This theory asserts that results *a*, *b*, and *c* are probable in calculable proportions, and by prolonging the experiment it is possible to verify the theory, if true, to any degree of accuracy required. Each experiment is really a quite separate one and the only feature in common is that you believe them to be representable by the same theory.

Recently Born has pointed out that quantum indeterminacy has wider implications than one might suppose. Consider, for example, the Brownian movement. In what possible circumstances can the motion of the tiny drops of butterfat seen in a microscope moving about in all directions in the liquid be regarded as determinate? Their motion in the view of nineteenth-century physics is controlled by the collisions they make with the molecules of the liquid, but who is to calculate the initial positions of the molecules of the liquid and their collisions with one another? To make the matter a little more definite let us imagine a more precise experiment. Suppose that we have a Geiger counter divided into two halves by a grid and filled with gas at suitable pressure. Let us introduce a single radioactive atom into this counter, at a known place. The atom is supposed to stick to a wall of the counter as soon as it touches, as it eventually will. Now try to calculate in which half it will end up. It will explode sooner or later and that half will be discharged giving an observable effect. To attempt to predict this, one would have to trace the zig-zag path of the atom diffusing through the molecules of the gas. If you try to consider the accuracy with which you would have to measure initially the positions and velocities of the millions of molecules concerned you will, I think, agree that to regard such an experiment as determinate is a misuse of language, even on the simplest assumptions such as assuming the molecules to act like billiard balls. The motion in each collision is sensitive to the position of the moving balls at the moment; a very small error in determining this will result in a big change in the direction and velocity of the balls after the collision, and so effect to a still greater extent all subsequent collisions. The errors in fact are magnified enormously, and long before the process comes to an end with the active atom reaching the wall, the initial accuracy required for prediction becomes fantastic. In the nineteenth century the physicist could say "yes, but in principle the motion is determinate". Since Heisenberg we can no longer do this; the motion is indeterminate. But I want to point out that this conclusion depends very little on the precise magnitude of *h* provided it is not absolutely and mathematically zero. I think that there are probably far more examples in practice of these truly indeterminate events than one is apt to suppose. One may be too impressed by the smallness of *h*. Take, for example, aerodynamics, where one is concerned with turbulent motion set up as an instability, as when, owing to changed speed, the laminar boundary layer of an aerofoil changes to a turbulent one. This may depend, of course, on roughnesses on the surface and therefore be determined by them, but it is quite likely if the surface is smooth that the instability is triggered off by a fluctuation, in the kinetic theory sense of the term, and it is within limits indeterminate when and where this happens. Most cases of instability are like this; they may become determinate because of some deviation from the ideal in the geometrical shapes, but if these are accurate enough there will come a time in which wholly unpredictable micro-effects will set the instability off. It seems quite likely that details of meteorology may be unpredictable in this fashion, and even quite major features may depend on unpredictable events in the Sun. All physics can do is to predict probabilities, not merely for atomic events but also for many other classes even where large effects are concerned. There are a great many trigger actions in Nature, especially where biology comes in.

It is perhaps scarcely necessary to urge that the discovery of new effects is fully as important a test of the merits of a theory as the explanation of old ones; but some writers on the philosophy of science seem to regard the main duty of a theory as the proper ordering and correlating of known facts. This seems to me an unimaginative view. In the past, theories have gone much beyond the known facts and profoundly helped physics by doing so Maxwell's equations connected the velocity of light with the ratio of electrostatic and electromagnetic units, but they also suggested waves of very different lengths, some of which Hertz discovered, and the theory also inspired von Laue to try X-ray diffraction The idea that many crystals are formed by the close-packing of nearly spherical atoms was put forward by Pope and Barlow , their theory was wrong in detail, but suggested to Bragg ideas now fundamental in the study of crystals

Imagination indeed is one of the qualities which mark the great scientist Even a hint of it may lift a man out of the rut. There is only one quality which is more important and that is enthusiasm, the feeling that science is the one thing that really matters and that to be allowed to spend one's life in its pursuit is the greatest possible privilege

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION, AUSTRALIA

DIVISION OF FOOD PRESERVATION · NEW LABORATORIES

THE Division of Food Preservation of the Commonwealth Scientific and Industrial Research Organization, Australia, has moved into new laboratories at North Ryde, New South Wales. This Division began its work in 1932 in laboratories situated in the Brisbane Abattoir, Queensland, where a branch laboratory is still maintained In 1938 the Division transferred its headquarters to laboratories in the Abattoir at Homebush, New South Wales, but in twenty years outgrew the accommodation there

The new laboratories are located on an elevated site, about eight miles from Sydney, in an area that is being preserved as a green belt to the city. Eleven buildings with a total floor area of 71,000 sq. ft are set in landscaped grounds about 10 acres in extent The disposition of the buildings on the site was determined largely by a desire to provide for future extensions to individual buildings without interference with other buildings and services

In the centre of the site (Fig 1) are the service facilities—workshops, stores, boiler house, engine room, and canteen, and also a Taste-Testing Laboratory, which has been carefully planned to provide a standard environment for sensory testing Flanking

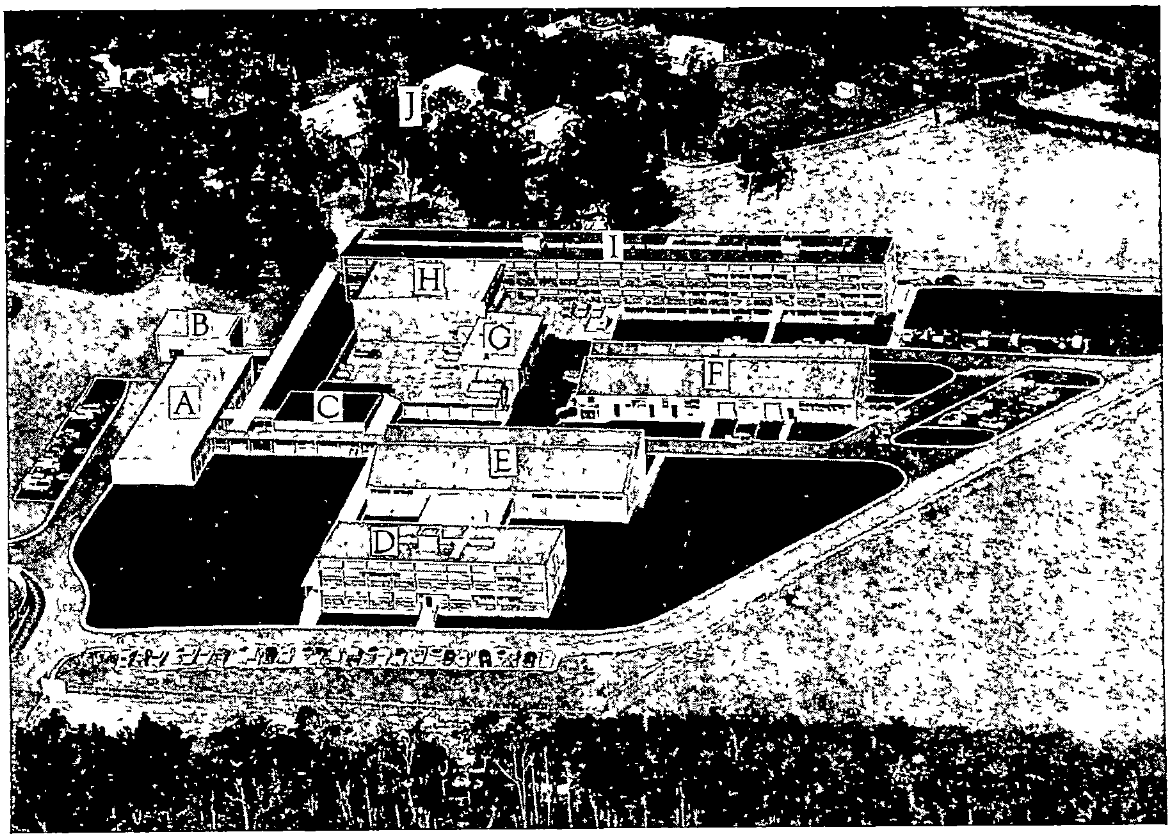

Fig 1 Aerial photograph of the new laboratories of the C S I R O Division of Food Preservation *A*, administration, *B*, Hicks meeting room, *C*, canteen and Taste-Testing Laboratory, *D*, food technology, *E*, food processing, *F*, workshops, *G*, boiler house and engine room, *H*, cold room block, *I*, food science, *J*, Bread Research Institute

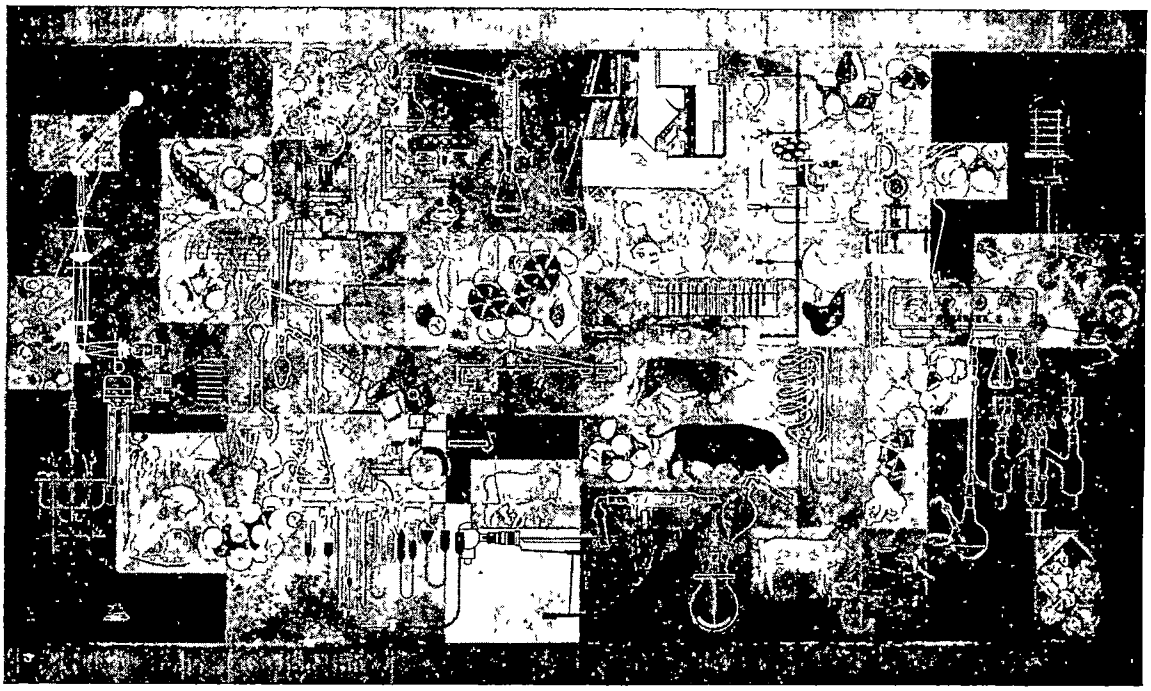

Fig. 2. Mural by Miss Eileen Mayo which decorates the foyer of the administrative building in the new laboratories

these buildings to the east are a single-storey building housing administration and the library, and the E. W. Hicks Meeting Room, named in honour of a pioneer member of the Division. On the south side of the site is the Food Science Building, which contains forty laboratories and accommodates the Physics, Chemistry, and Microbiology Sections, and also the Fresh Fruit and Vegetable Storage Section, and an Animal Products Section dealing with meat, fish, poultry and eggs. The other technological Sections of the Division—Canning, Packaging, Dried Foods and Frozen Foods—occupy the twenty-two laboratories in the Food Technology Building, and also use the adjoining Food Processing Building, where there is an open processing area 130 ft. × 50 ft., containing pilot-scale equipment for the production of experimental packs of processed foods. In a separate building is a sulphuring room for work on the treatment of dried fruits with sulphur dioxide and a chemical processing laboratory for operations involving volatile solvents.

The laboratory buildings have a central corridor with load-bearing walls in brick, and reinforced concrete supporting piers at 12-ft. centres on the external walls. Aluminium has been used for roofs and window frames, and also for the coloured enamelled spandrels, which are removable for access to the services running in perimeter ducts along the north and south walls. Penetration of summer sunshine on the long north and south sides of these buildings is controlled by continuous concrete hoods and vertical pre-cast concrete fins. The hoods also act as working platforms when access is required to the perimeter ducts.

The services available in the laboratory blocks are hot and cold water, distilled water, gas and alternating-current power, with compressed air and steam in some laboratories. Fume cupboards are provided with individual exhaust fans, and in some sections separate fume rooms containing two fume cupboards have been installed. Water and gas are run in copper pipes, distilled water in stainless steel, and sink wastes in polythene and glass piping. The library, the taste-testing booths, and several specialized laboratories are air-conditioned, while the remaining buildings are heated by hot-water radiators.

The buildings are linked by an internal road system and by covered footways which also provide overhead carriage for some services.

Two general types of layout have been used within the laboratories, according to whether the function is predominantly chemical or biological, but officers were given considerable freedom in the detailed planning. A variety of service rooms has been provided, ranging from balance and instrument rooms to a suite of preparation and sterilizing rooms for microbiological work. Many of the internal partitions are removable to permit changes in layout, and bench units and service lines can be readily dismounted and re-used. Laboratory bench tops are solid timber finished with a clear epoxy resin, while fume cupboards are finished in a white pigmented epoxy resin. Natural wood finishes have been used extensively on laboratory furniture, and in conjunction with the light-coloured walls the general effect is very pleasing.

In a wing of the Food Science Building are 31 controlled-temperature rooms with a range of constant temperatures from −30° C. to 50° C. Four of these rooms are gas-tight for the storage of food in controlled atmospheres.

Immediately adjoining the Division of Food Preservation at North Ryde is the Bread Research Institute of Australia, a research association financed by the Bread Baking industry and the C.S.I.R.O. jointly, and this Institute houses a C.S.I.R.O. Wheat Research Unit. There is thus a useful centralization of food research establishments at North Ryde.

The Division of Food Preservation has a total staff of 150, of whom 78 are graduate research officers and experimental officers, and 49 are technical assistants The field of research in which these workers are engaged is the handling, preservation, processing, storage and transport of meats, fish, eggs, fruits and vegetables More than half the resources of the Division are devoted to fundamental research seeking a deeper understanding of the properties of foods and the changes which they undergo during processing and preservation In addition, therefore, to technological projects on the preservation of foods by canning, dehydration, and refrigeration, the research programme includes many projects in the basic sciences

Present chemical research is concerned with applications of gas chromatography to volatile constituents of foods, with anthocyanin and other flavonoid pigments in foods, and with reaction mechanisms in the non-enzymatic browning of foods and its control by sulphur dioxide Workers in muscle biochemistry are elucidating the effects of rigor mortis and freezing on the protein and other constituents of muscle Theoretical work on physics, on heat- and mass-transfer across laminar boundary layers, are related to many problems encountered by food technologists Fundamental microbiological studies on the effects of water activity on microbial growth and on the germination and growth of bacterial spores are designed to give precise information on factors governing the control of micro-organisms which cause food spoilage and food poisoning Studies in plant physiology on the metabolism of carbohydrates and organic acids and on the properties of plant cell membranes are related to outstanding problems in the preservation of fruits and vegetables

The new laboratories were officially opened on September 18 by Dr. D A Cameron, Federal Minister for Health and for the C S I R O , in the presence of a large gathering of representatives of Government and university departments and the Australian food industry On the four days following, a Food Science Conference was held and was attended by 250 Australian food scientists and technologists and a few overseas visitors. The programme included symposia on "Chemical Aspects of Food Processing" led by Prof C O Chichester of the University of California, Davis, on "Meat Quality" led by Dr E. C Bate-Smith, Low Temperature Research Station, Cambridge, and on "Food Preservation and the Organization of Plant and Animal Tissues" led by Dr J B Biale, University of California, Los Angeles, and also panel discussions on public health aspects of handling and processing foods and on trends in food research

UNCONVENTIONAL METHODS OF ENERGY CONVERSION

A JOINT session of Sections A (Mathematics and Physics) and G (Engineering) of the British Association was held in Norwich to discuss the present situation with conventional methods of converting heat into electricity, the need for new methods, the principles of the new methods on which research is in progress, and the prospects for the future

In the opening paper, Prof. T G Cowling (University of Leeds) pointed out first that with the established methods of using solar energy indirectly, by fossil fuel or by water-power, the proportion of the incident energy which is utilized for energy conversion is extremely small This proportion is nevertheless, up to the present, readily available The nuclear fission process is now well established, and can be controlled and made available satisfactorily The direct employment of solar energy is, however, difficult because, although 1 5 kW /m ^{2} arrives from the Sun outside the Earth's atmosphere, the problems of concentration mean that it is not readily available Even greater difficulties with availability of the energy apply, of course, to thunderstorms, and so far to nuclear fusion processes Thus, there are no new sources of energy likely to compete for some time with the existing sources For new methods of utilizing existing sources of energy, those of interest appear to be thermoelectricity, the thermionic diode, magnetohydrodynamics and the fuel cell The last of these was omitted from this session, and dealt with in a meeting of Section G on the following day

Mr F H S Brown (Central Electricity Generating Board), in the second paper, considered the incentives for establishing unconventional methods of energy conversion The conversion of mechanical energy to electrical is now very efficient indeed, and the problem remaining with conventional methods is the conversion of heat to mechanical energy This is, of course, limited ultimately by the efficiency of the Carnot cycle, though the best efficiency obtained is only about 70 per cent of this To raise the efficiency of the Carnot cycle requires an increase in the temperature at which heat is fed into the cycle With present materials, no engine with highly stressed moving parts can be operated continuously at a temperature much above 600° C Thus, although a fuel may be burned at 1,700° C , no such temperature can be fed into an engine continuously. In the internal combustion engine, the explosion produces a high temperature which falls rapidly during adiabatic expansion, thus lowering the mean temperature of the engine parts However, there is a limit in practice to the size of the internal combustion engine, it is expensive, and moreover, since it is of the reciprocating type, it suffers from friction, wear and noise to an unacceptable degree

The steam cycle is thus more satisfactory, although it has a limiting temperature near 600° C The efficiency obtainable is about 40 per cent, and in this case, unlike the internal combustion engine, scaling up improves the performance obtainable The gas turbine involves again continuous exposure to the maximum temperature, the limit of which at present is near 600° C ; but a better performance can be obtained compared with the steam cycle because of the lower pressure and the larger heat rejection at the minimum temperature of the cycle

It is clear that it would be very desirable to increase overall efficiency above 40 per cent, and the methods of achieving this could in principle be: (1) finding an intermittent process cheaper and more reliable than the internal combustion engine, (2) evolving better materials for use at high temperatures, for example, up to 1,700° C , (3) evolving a continuous method which does not stress working parts at high temperatures

In the third paper, Dr R G Siddall (University of Sheffield) described the work of Prof M W Thring and himself on producing electricity directly from fast-moving plasmas Here the ionized gas of the plasma replaces the conductor in a dynamo, and moves through a magnetic field, converting its kinetic energy directly into electricity To obtain useful power, the plasma must have an electrical conductivity near 1 ohm^{-1} cm.$^{-1}$, and it must move at several thousand miles per hour through a magnetic field of 10,000–20,000 oersteds Moreover, the path-length through this field to extract the energy must be many feet Ordinary gases would have too low a conductivity at any feasible temperature, but by 'seeding' with a small proportion (say 1 per cent) of the vapour of an alkali metal, temperatures near 2,500° C would be sufficient The simplest scheme would be to preheat air, compress it and mix with a fuel, burn it at about 2,500° C , and expand through a nozzle to obtain the velocity Unfortunately, this would cool the gas almost to 1,000° C , to maintain it near 2,500° C after expansion would need a combustion temperature near 6,000° C Thus, more sophisticated schemes are necessary

Three ideas due to Prof Thring are under investigation First, continuous combustion at 2,500° C followed by expansion through a nozzle is used to produce the high velocity Secondly, short bursts of preheated oxygen and fuel seeded with potassium are injected periodically into the combustion chamber immediately before the expansion nozzle This burning gas is swept along in 'slabs' by the main gas stream These slabs are expected to retain their initial temperature during their passage through the magnetic field The second scheme involves obtaining the high velocity without pre-compressing and expanding The combustion occurs at constant volume, in a chamber with inlet and exit valves which achieve pulsating combustion, so that again the hot gas passes in slabs through the magnetic field

The third idea utilizes shock waves produced successively at the opposite ends of a tube, so driving a plasma to and fro through the magnetic field This will generate power at each passage, and will produce alternating current It is thought that these methods, if successful, will produce efficiencies of 50–60 per cent

Mr P Dunn (Atomic Energy Research Establishment) described, first, the basic principles of the thermionic diode as an energy converter, using the analogue of the steam boiler to illustrate the electron evaporation from the cathode and collection at the anode He showed that for a given cathode operating temperature, the cathode work function should be below a maximum allowed value which is a function of the operating temperature, but that there is no optimum value He indicated the importance of low anode work function, and of minimizing the effects of space charge either by using very close-spaced vacuum diodes or by positive ion neutralization of the space charge The former method is impracticable for generation of large amounts of power, though it is valuable for space vehicles With cathodes operated at 1,400° K , present diodes give an output of 0 7 V , 1 amp /cm ^{2}, with an efficiency near 15 per cent Higher outputs and efficiencies will be obtained with higher cathode temperatures For use in a reactor, supposing that the fuel elements could be run at temperatures up to 2,000° C , but not higher, a cathode with a work function less than 3 eV would be required This cannot be a metal, and none of the known oxides used as cathode materials is satisfactory at 2,000° C Uranium carbide has, however, a work function near 3 eV , and may be useful both as cathode material and, suitably enriched, as the fuel element Using cæsium vapour to give the positive ions, this should maintain a cæsium coverage on the anode which would give a reasonably low anode work function It is not certain yet whether the cæsium would be adequately ionized in such a diode, and it is known that there are considerable difficulties in using cæsium due to attack of other metals, glass and ceramics Thus other forms of ion injection are under investigation

The thermionic diode is conveniently used with fission nuclear power, as it is easy to obtain the required heat flux to the cathodes To produce a plasma jet would not be easy with a reactor Conversely, with fossil fuel, it is not difficult to produce such a jet, but the heat flux to a cathode is difficult to obtain The thermionic diode is suitable for 'topping', in that the heat injected at the cathode at 2,000° C is conveniently rejected at the anode at temperatures of 400–600° C , so that it could then be used in a conventional steam cycle The thermionic diode therefore promises a useful step forward under the third heading above Incidentally, the high-velocity plasma cannot be used after the hottest part of the gas has cooled below about 2,000° C , so that this method could also be used for topping

In the final paper, Prof D A Wright (University of Durham) discussed thermoelectricity as a means of generating power directly from heat He first outlined the basic principles, showed why the performance of metallic thermojunctions was poor, and contrasted the possibilities with semiconductors. With the latter there are many complications, but the main requirements with the 'broad-band' type are that they should have a sufficiently high energy gap, depending on the required temperature of operation, that it should be possible to prepare them n-type or p-type, with a Seebeck coefficient α near $\pm$ 200 μV /deg C , and that they should then have a high electrical conductivity σ and a low thermal conductivity K The usefulness of a material is, in fact, determined by the quantity zT, where $z = \alpha^2\sigma/K$ and T is the absolute temperature It would be necessary to prepare the material reliably and repeatably, reasonably cheaply, with a high degree of uniformity of properties over every sample, from sample to sample, and from batch to batch It must be possible to make low-resistance reliable contacts, and the material must not melt or decompose in operation, the deliberately added impurities must not diffuse out, and impurities from the contacts or from the environment must not diffuse in

One of the best materials so far is bismuth–antimony–telluride, which has a value of zT slightly greater than unity, but cannot be operated above 150° C , because of its low-energy gap With the hot junction at 150° C , cold junction at 0° C , a thermojunction between p- and n-type material would give a junction efficiency near 7 per cent Lead telluride can be operated at 500° C , but with zT less than unity, so that the junction efficiency between 500° C and 0° C is about 12 per cent Unfortunately, the figures realizable in practice are lower than these because of resistance at contacts, temperature drop at contacts, and, with fossil fuels, problems of heat transfer to the hot junctions following combustion

Progress in finding materials which can be operated at higher temperatures is slow because there are incompatibilities in the requirements To obtain higher energy gaps and so permit higher operating temperatures one needs compounds of lower atomic weight which, compared with bismuth and lead tellurides, tend to have higher thermal conductivities and lower values of the electrical conductivity for a given Seebeck coefficient Thus the trend is for materials which can be operated at higher temperatures T to have lower values of z, and in fact zT, than materials which can be operated only at low temperatures Indium arsenide containing gallium or phosphorus can be operated to about 700° C , but zT is only about 0 5 More promising are some compounds such as $AgSbTe_2$ and its analogues formed by cross-substitution from the same columns of the Periodic Table These have lower thermal conductivity than their mean atomic weight would predict Values of zT as high as 1 5 up to 700° or 800° C seem likely to be attained with these compounds Materials which could be operated to 1,100° or 1,200° C have so far lower values, for example, cerium sulphide, zT near 0 5, and nickel oxide, zT still lower Thus the highest junction efficiency which is theoretically obtainable at present between 1,200° C and 0° C is about 17 per cent, while the best actually obtained so far for this range is only about 6 per cent This is in a 'cascaded' system in which three or four stages are used, the heat from the first stage passing to the second and so on, and different materials being used in the different stages, to match the temperature involved

To obtain useful performance for 'topping' in power generation, values of zT near unity would be necessary at temperatures up to 1,600° C , while for direct replacement of present generators operating up to 600° C , values of zT would have to exceed 4 There seems little prospect at present of obtaining values as high as this in either temperature-range Meanwhile, research is continuing, and this type of generator is useful in spite of low efficiency for the production of low power in portable equipment and in remote situations where such a generator has to run unattended for long periods

D A WRIGHT

THE INTERNATIONAL COUNCIL OF SCIENTIFIC UNIONS

THE ninth assembly of the International Council of Scientific Unions (ICSU) met in London during September 25–28 under the auspices of the Royal Society About 130 delegates attended, each representing a particular scientific discipline or organization They came from all continents, and all, to quote Prof A V Hill, were working scientists of the world If the Council were a political union, it might be better known In his welcoming address Sir Howard Florey described it as a living example of voluntary international co-operation by scientific men themselves in the best use of science to serve a world community, and in educating the public about the real purpose of scientific knowledge and research Many changes in the modern world, although often described as social or economic, may stem more directly from the growth and applications of science itself To say, however, that science has now become so big that it is a matter for Governments alone is a dangerous half-truth, for freedom of thought and objective analysis are essentials which must be preserved, unencumbered by an excessive bureaucracy or by considerations of political expediency The principles and aims of science are not national but universal International co-operation is no longer just a matter of nomenclature, symbols or standards, we have reached a stage when measurements on a particular phenomenon may be useless unless made simultaneously at widely separated places We must also consider, for example, the effects of space research or of nuclear explosions not only on the future progress of scientific research on the cosmos itself but even more specifically on the world as a place for humanity or any other biotic community No observer at this assembly could fail to sense in this distinguished gathering an underlying realization of responsibility by scientists themselves of all lands, to apply their knowledge and such influence as they may possess for the benefit of all mankind

The International Council of Scientific Unions was established in 1931 Its precursor, the International Research Council, had been set up in 1919 but proved unsatisfactory because it was restrictive, in no sense fully international, and because it allowed feelings engendered by the First World War to cloud its proper function These mistakes were avoided after the Second World War, and the recent assembly reaffirmed its previously declared non-political philosophy by admitting to membership under the terms of its rules Hungary (Academy of Sciences), North Korea (Academy of Science, Phyongyang), South Korea (Academy of Science, Seoul), Ghana (Academy of Learning), Ceylon (Association for the Advancement of Science), and East Germany (Berlin Academy of Sciences)

The Council has several objects It aims to coordinate the activities of the international scientific unions, and to be a co-ordinating centre also for the national organizations which are in membership It seeks to encourage scientific activity in fields which do not fall directly within the scope of any existing organization, to enter through the national organizations into relations with Governments and to maintain relations with the United Nations and its Specialized Agencies The Council consists of national members and scientific members There are now fifty-one national members, each representing the authoritative scientific organization in the country concerned—an academy, national research council or similar institution or, in a very few cases where no appropriate body exists, the Government itself Fourteen international unions are now members Of these, the general unions include astronomy (IAU), biology (IUBS), pure and applied chemistry (IUPAC), geodesy and geophysics (IUGG), geography (IGU), pure and applied physics (IUPAP), mathematics (IMU), and geology (IUGS), which was admitted at the recent Assembly The specialized unions include crystallography (IUCr), history and philosophy of science (IUHPS), theoretical and applied mechanics (IUTAM), scientific radio (URSI), physiology (IUPS), and biochemistry (IUB)

ICSU has neither the wish nor authority to interfere with the autonomy of these unions, nor to disturb the work which they are specifically designed to undertake The range of their work is enormous It includes the arranging of international symposia on matters of universal importance, the preparation of reports by specially appointed commissions, and the instigation and organization of research which requires international collaboration For example, IAU has dealt with atomic time standards, and has helped astronomy and space research Through its activity, also, many astronomers have been enabled to obtain the use of instruments in countries other than their own IUGG has concerned itself with problems of Earth and its atmosphere, such as earthquakes and volcanoes, the atmospheric absorption of solar radiation, and the levels of oceans and the penetration of radiation into them The data which it has collected are published and available to anyone In the future it will participate in projects of the International Committee on Geophysics (CIG) discussed later IUPAC has recently published reports on nomenclature and terminology, on internationally agreed analytical standards, on problems of foods and fats, and in collaboration with IUPAP has laid down a revised scale of atomic masses based on carbon-12 IUBS has dealt with quantitative methods in pharmacology and toxicology and with problems of cellular biology, embryology and genetics, and IUB has made a complete survey of known enzymes URSI has been considering the results of the International Geophysical Year (IGY) in relation to the ionosphere, problems of radio communications in space, and has given advice about the allocation of frequency channels. IUTAM has studied the problems of atmospheric pollution, and IGU has set up groups to deal with new world maps, erosion and coastal geomorphology, and the problems of humid tropics or arid zones

The function of ICSU is to co-ordinate and integrate the work of the different disciplines, and to catalyse research in fields not covered by the separate organizations For the latter purpose, special committees have been set up, supported in the early stages by funds from ICSU, although each must later find support through the participating national organizations A strikingly successful example was the International Geophysical Year, in which 67 countries took part, some 2,000 observing stations being established, 57 of them in the Antarctic The results accumulated during this project are still being analysed, but publication will soon be complete In order to exploit this success, the International Committee of Geophysics (CIG) was set up, with more than 60 national committees, the appropriate unions and the World Meteorological Organization taking part, to maintain the operation of the World Data Centres, to ensure further inter-disciplinary co-operation and to arrange universal publication of the relevant scientific data Its future plans include a World Magnetic Survey, the study (1962–65) of Earth's Upper Mantle—a 1,000-km crust, and in 1964–65 the International Year of the Quiet Sun (IQSY) IQSY will obtain data on geomagnetism, aurora, airglow, the ionosphere, solar physics, cosmic rays and space research during a period of sun-spot minimum, complementary to those obtained in the IGY period of sun-spot maximum

Another special committee is SCOR, dealing with oceanographic research of all kinds There is the effect of circulation on the welfare and migration of the plankton, the spread of radioactive wastes, the study of surface waves in relation to the design of ships or to erosion, and new methods of studying the sea floor More specifically SCOR has planned for 1963–64 an Indian Ocean expedition, in which at least thirteen countries and more than forty ships are expected to co-operate, and for which a good deal of reconnaissance has already been completed The expedition will make measurements on marine geology, geophysics and bathymetry, physical, chemical, and biological oceanography, and meteorology from the air-sea interface to the upper atmosphere The results may lead to a better understanding of the natural factors which affect the large population living in countries bordering on the Indian Ocean

The Special Committee on Antarctic Research (SCAR), has continued work along the lines of the IGY, involving a long-term programme of measurements at many stations on a variety of geophysical matters Twelve nations are at present taking part and the agreement by treaty to freeze all territorial claims for some thirty years shows a high degree of co-operation Advice sought from SCAR by several Governments has been freely given

Another descendant of the IGY is the Special Committee on Space Research (COSPAR) which aims to use rockets or rocket-propelled vehicles for carrying out scientific research in the widest sense In the public eye, space science is loaded with military and commercial interests and also provides some satisfaction to sensation-hunters It is most important, however, to preserve in proper perspective unbiased space research on a world-wide basis and to ensure that the top scientists concerned are maintained in personal contact COSPAR, first set up by ICSU in 1958, had many problems in its first year, but under an agreed charter (1959) can now hope to perform a valuable service It is not concerned with technical problems of rockets or with manned space flights Ten of the international unions and 16 national members are affiliated to it, and relations are maintained with the United Nations, the World Meteorological Organization, and the International Telecommunications Union, all Governmental bodies COSPAR is only just beginning to achieve its object, but two examples may serve to illustrate its potential value First, if the science of radio astronomy and of space research itself is to be continued at all, some frequency bands must be kept free from interference The 21-cm band has at present been exclusively preserved, but as Earth-to-Earth communication by satellites for commercial, military or other purposes is developed, larger parts of the spectrum will be claimed COSPAR, with IAU and USRI, must explain and emphasize the need Secondly, space experiments are now possible, or even in progress, which may for ever prevent some aspects of proper scientific research quite apart from their damaging effects on mankind The creation of a belt of needles, in the project 'West Ford' was considered as possibly hampering or even stopping future work on both optical and radio astronomy For these sound reasons, the ICSU Assembly agreed unanimously to invite COSPAR "to examine any proposed experiments or other space activities that may have potentially undesirable effects on scientific activities and observations, to arrange for careful objective quantitative studies and to make available to unions, academies, and at contacts, and, with fossil fuels, problems of heat transfer to the hot junctions following combustion

Progress in finding materials which can be operated at higher temperatures is slow because there are incompatibilities in the requirements To obtain higher energy gaps and so permit higher operating temperatures one needs compounds of lower atomic weight which, compared with bismuth and lead tellurides, tend to have higher thermal conductivities and lower values of the electrical conductivity for a given Seebeck coefficient Thus the trend is for materials which can be operated at higher temperatures T to have lower values of z, and in fact zT, than materials which can be operated only at low temperatures Indium arsenide containing gallium or phosphorus can be operated to about 700° C , but zT is only about 0 5 More promising are some compounds such as $AgSbTe_2$ and its analogues formed by cross-substitution from the same columns of the Periodic Table These have lower thermal conductivity than their mean atomic weight would predict Values of zT as high as 1 5 up to 700° or 800° C seem likely to be attained with these compounds Materials which could be operated to 1,100° or 1,200° C have so far lower values, for example, cerium sulphide, zT near 0 5, and nickel oxide, zT still lower Thus the highest junction efficiency which is theoretically obtainable at present between 1,200° C and 0° C is about 17 per cent, while the best actually obtained so far for this range is only about 6 per cent This is in a 'cascaded' system in which three or four stages are used, the heat from the first stage passing to the second and so on, and different materials being used in the different stages, to match the temperature involved

To obtain useful performance for 'topping' in power generation, values of zT near unity would be necessary at temperatures up to 1,600° C , while for direct replacement of present generators operating up to 600° C , values of zT would have to exceed 4 There seems little prospect at present of obtaining values as high as this in either temperature-range Meanwhile, research is continuing, and this type of generator is useful in spite of low efficiency for the production of low power in portable equipment and in remote situations where such a generator has to run unattended for long periods

THE INTERNATIONAL COUNCIL OF SCIENTIFIC UNIONS

THE ninth assembly of the International Council of Scientific Unions (ICSU) met in London during September 25–28 under the auspices of the Royal Society About 130 delegates attended, each representing a particular scientific discipline or organization They came from all continents, and all, to quote Prof A V Hill, were working scientists of the world If the Council were a political union, it might be better known In his welcoming address Sir Howard Florey described it as a living example of voluntary international co-operation by scientific men themselves in the best use of science to serve a world community, and in educating the public about the real purpose of scientific knowledge and research Many changes in the modern world, although often described as social or economic, may stem more directly from the growth and applications of science itself To say, however, that science has now become so big that it is a matter for Governments alone is a dangerous half-truth, for freedom of thought and objective analysis are essentials which must be preserved, unencumbered by an excessive bureaucracy or by considerations of political expediency The principles and aims of science are not national but universal International co-operation is no longer just a matter of nomenclature, symbols or standards, we have reached a stage when measurements on a particular phenomenon may be useless unless made simultaneously at widely separated places We must also consider, for example, the effects of space research or of nuclear explosions not only on the future progress of scientific research on the cosmos itself but even more specifically on the world as a place for humanity or any other biotic community No observer at this assembly could fail to sense in this distinguished gathering an underlying realization of responsibility by scientists themselves of all lands, to apply their knowledge and such influence as they may possess for the benefit of all mankind

The International Council of Scientific Unions was established in 1931 Its precursor, the International Research Council, had been set up in 1919 but proved unsatisfactory because it was restrictive, in no sense fully international, and because it allowed feelings engendered by the First World War to cloud its proper function These mistakes were avoided after the Second World War, and the recent assembly reaffirmed its previously declared non-political philosophy by admitting to membership under the terms of its rules Hungary (Academy of Sciences), North Korea (Academy of Science, Phyongyang), South Korea (Academy of Science, Seoul), Ghana (Academy of Learning), Ceylon (Association for the Advancement of Science), and East Germany (Berlin Academy of Sciences)

The Council has several objects It aims to co-ordinate the activities of the international scientific unions, and to be a co-ordinating centre also for the national organizations which are in membership It seeks to encourage scientific activity in fields which do not fall directly within the scope of any existing organization, to enter through the national organizations into relations with Governments and to maintain relations with the United Nations and its Specialized Agencies The Council consists of national members and scientific members There are now fifty-one national members, each representing the authoritative scientific organization in the country concerned—an academy, national research council or similar institution or. in a very few cases where no appropriate body exists. the Government itself Fourteen international unions are now members Of these, the general unions include astronomy (IAU), biology (IUBS), pure and applied chemistry (IUPAC), geodesy and geophysics (IUGG), geography (IGU), pure and applied physics (IUPAP), mathematics (IMU), and geology (IUGS), which was admitted at the recent Assembly The specialized unions include crystallography (IUCr), history and philosophy of

Governments the facts and analyses needed by them for making wise and proper decisions concerning the proposed experiments" It further appealed to all Governments planning to launch space experiments which could possibly affect other scientific research adversely to make available to ICSU the information and data about the proposed experiments in sufficient time to ensure their proper consideration

ICSU has other commitments The Federation of Astronomical and Geophysical Services (FAGS) provides an international time bureau, a gravimetric bureau, and Earth tide service and a central ursigram service for the transmission of coded ionospheric, solar and geomagnetic data The Joint Committee on Radioactivity (JCAR) provides standardization of radioactive isotopes, and is linked with the International Atomic Energy Agency The ICSU Abstracting Board has done much to co-ordinate abstracting in both physics and chemistry Funds are also to be sought so that a revised set of bathymetric charts of the oceans can be published An international committee has recently been set up to examine the teaching of science at university level

The London assembly took an important decision to initiate a world-wide programme for studying the biological basis of human welfare The physical and biological condition of the surface of Earth is undergoing a more rapid and extensive change than might ever have been expected Much of this change is due in one way or another to the development and application of physical and medical science. Desirable as much of this may be, some of the influences may lead to serious changes in the frequency of certain genes Higher levels of radioactivity, too, although at an apparently insignificant dose-level, may in the long term be harmful to the progeny of man or animals or plants We need not only to investigate these problems, but also to educate the public on how to preserve satisfactory world conditions ICSU has therefore resolved to study, through the Unions of Biology, Biochemistry and Physiology, the effect on living communities of changes in natural environment, and the augmentation through basic research of natural resources and the reduction of losses and waste It is hoped to examine the somatic and genetic variation induced by environmental factors on man and other organisms, at the individual and population levels, and to find the best means for the preservation of biotic communities which are in danger of destruction or transformation In planning this programme it is intended in the first place to restrict it to clearly defined small projects of limited scope which can only be done by international co-operation The work will be basic in character and although it will be co-ordinated with related activities of a more applied kind being carried out by such bodies as UNESCO, FAO, WHO, or IUCN, it will involve no duplication

It is not surprising that after a period of such ferocious development the question has been raised whether the structure and mechanism of ICSU as laid down thirty years ago needs some revision The great activity of the separate international unions may have concealed the importance of the national academies Yet these latter have a vital part to play, especially to prevent a too extensive fragmentation of science, and through interdisciplinary integration to preserve science as a whole They, too, by contact with Governments, are primarily involved in the search for funds The whole structure must be designed to allow for this, and to ensure a satisfactory geographical distribution of members while still preserving both efficiency and flexibility Also, one cannot escape the fact that this enormous growth of activity requires a larger central secretariat in the headquarters which are shortly to move from The Hague to Rome Yet policy must always be decided by scientists themselves, and bureaucracy must be limited to the essential minimum More money is needed. The Assembly agreed to double the subscriptions of National Members and to ask for additional voluntary contributions UNESCO, an inter-Governmental organization, has certain overlapping interests with ICSU, but a mutually beneficial arrangement has been maintained, and UNESCO has continued to transfer funds to ICSU for use by the unions and special committees which are carrying out work in which it has a direct interest and on which it frequently seeks advice

The ICSU Assembly has appointed a special committee to examine all these problems of structure and operation in the near future Dr E W R Steacie, who succeeds Sir Rudolph Peters as president, will have charge of this committee. The next general assembly is planned for 1963 or 1964 in Zurich

The spirit of ICSU to-day can still be expressed by the resolution of the 1946 assembly, also held in London, acknowledging the duty of scientific workers (*a*) to maintain a spirit of frankness, honesty, integrity and co-operation and to work for international understanding, (*b*) to promote the development of science in the way most beneficial to mankind and to exert their influence as far as possible to prevent its misuse, (*c*) to serve the community not only by their specialized work but also by assisting so far as they are able in the education of the public in the purposes and achievements of science

OBITUARIES

Mr. B. B. Osmaston, C.I E

B B OSMASTON, known to many in India as "B B", was born at Yeldersley Hall, Derbyshire, in 1867, the ninth of a family of fifteen, two of whom survive him He was educated at Cheltenham and at the Royal India Engineering College at Coopers Hill, where those entering the India Forest Service were then trained He passed in and out first of his year at Coopers Hill, and was made a Fellow of the College He joined the Forest Service in India in 1888, and served in the United Provinces (including Dehra Dun Forest College), Bengal, the Andaman Islands, a short time in Burma, and finally retired as chief conservator of the Central Provinces, being appointed C I E

After retirement he lived with his family for some time at Srinagar in Kashmir, and for the rest of his life he lived at Oxford

In 1892 he married Catherine Mary, daughter of General and Mrs Hutchinson, and they had sixty-eight years of married life together His wife died in 1960 but two sons and three daughters survive him, one son having been killed in the First World War

He was keen on any natural science subject which he took up chemistry, botany, spiders and, above all, ornithology He loved birds from boyhood, and he was very familiar with the habits and songs of Indian birds

Mr Osmaston's life in the jungle inevitably brought a large share of excitement and adventure in the form of encounters with dangerous wild animals, but one of the most exciting occurred within three months of his arrival in India, and is well worth recording again He was posted to the district of Jaunsar in the hills, where there had been a man-eating tigress taking a toll of human life for ten years Mr Osmaston, then aged twenty-one, and a forest student named Mr Hansard, decided to try to stalk the tigress in the heat of the day, when, they felt sure, she would be lying up in some secluded place They went cautiously down a steep ravine which was covered with thick scrub one of them on each side of the steep banks bordering the small stream They had not been going for more than five minutes when Mr Osmaston heard a scuffle and a terrible noise of growling, mixed with cries and groans above him The tigress had stalked the stalkers, and had pounced on Mr Hansard from behind Mr Osmaston, who had never before seen a tiger outside a zoo, had to risk a shot at the tigress while she was mauling Mr Hansard The shot made the tigress let go her hold, and the second barrel discharged at her as she came headlong down the bank towards him finished her off Mr Hansard's life was saved, though he had been badly mauled, and the scourge of the countryside was dead Mr Osmaston had achieved what many a famous hunter had tried to do during the previous ten years

His adventures included an encounter on foot with the rogue elephant which had caused the death of Mrs Anson, an exciting escape from drowning when shooting some rapids in a canoe, navigating a small launch by compass and map without previous experience in order to find a certain uninhabited island in the Andamans which was reputed to be the only habitat of some very rare hornbills This adventure included the onset of a storm resulting in the loss of the landing boat while the party was ashore, which necessitated a dangerous swim in rough water infested with sharks, back to the launch, which was anchored in deeper water

These few incidents serve to show Mr Osmaston's adventurous spirit He was abstemious and thrifty all his life, and his disregard for personal comfort and safety took him to many strange and interesting places, and he had very wide knowledge of all things to do with life in the jungle

After retirement he participated in two strenuous expeditions in pursuit of further knowledge about birds, the first to Ladakh at very high altitudes, and the second in Africa Both these expeditions were undertaken in the company of his good friend Admiral Lynes, another keen ornithologist

By his death, at the age of ninety-three, the world has lost a very courteous, charming and adventurous personality

Dr T P Colclough, C.B.E.

TOM COLCLOUGH, as he was known to ferrous metallurgists, who died on September 22, aged seventy-six, was one of those rare personalities who commanded respect in both industry and research He was educated at the Universities of Manchester and Sheffield, and awarded the D Sc of Manchester and the D Met at Sheffield He entered the Brown–Firth Research Laboratories in 1916 under W H Hatfield and in 1920 became chief chemist at Park Gate Iron and Steel Co , Ltd He was appointed in turn chief metallurgist, open-hearth manager and technical officer In 1929 he became technical director of H A Brassert and Co and was directly concerned with subsequent developments at Corby, Ebbw Vale and other steel works His capacity for sensing the direction of developments in iron and steel contributed to an international reputation covering Germany, Austria Turkey, China and New Zealand

During the Second World War he was technical adviser to the Iron and Steel Control of the Ministry of Supply, and was appointed C B E for his services in 1947 In 1945 he continued in this field as technical adviser to the British Iron and Steel Federation, which post he held at the time of his death His post-war travel ranged from work with the Control Commission in Germany at the end of the War, to advise the Durgapur works in India and the R I S C O works in Southern Rhodesia He was the leader of British Iron and Steel Federation missions to the U S S R , Poland and Yugoslavia

Research was not forgotten amid this industrial activity, for he participated in the work of the British Iron and Steel Research Association, and from 1950 served as a member of its Council He was awarded the Bessemer Gold Medal of the Iron and Steel Institute in 1954, and elected an honorary vice-president of that Institute in May 1960

Until recently he delivered an annual lecture in the Department of Metallurgy at Manchester, which was always received with eager concentration by the students He had the power to hold the attention and stimulate his audience which scarcely changed with advancing years In these days of specialization, his combination of forward thinking with the necessary restrictions of practice was as welcome as it was unusual C R TOTTLE

Dr. E. McKenzie-Taylor, C.I.E , M.B.E.

DR E MCKENZIE-TAYLOR died at his home at Basildon on October 17 He was a North-country man and received his early training at Armstrong College, Newcastle upon Tyne, before the First World War, for a short time he was a demonstrator in agricultural chemistry there His first appointment elsewhere was as lecturer in agricultural science at the Harper Adams Agricultural College From there he moved to the East Anglian Institute of Agriculture at Chelmsford, where he became head of the Department of Agricultural Chemistry, and as such was concerned primarily with analytical work connected with agricultural problems

After service in the Royal Artillery during the First World War, he returned to Chelmsford until 1921, when he was appointed senior chemist to the Cotton Research Board of the Egyptian Ministry of Agriculture Here, with A C Burns, he carried out important work on the daily and seasonal changes in soil temperature and on other factors influencing the yield of cotton In particular, they investigated the steady decrease which had been experienced in the yield of cotton in Egypt during the previous quarter of a century, under intensive irrigation by free flow from the Nile

McKenzie-Taylor returned to Great Britain in 1926 and was appointed University lecturer in agricultural chemistry in the School of Agriculture at Cambridge, a post which he held until 1930 In that year he became director of irrigation research and land reclamation in the Panjab Here again he applied his active mind to the soil problems connected with irrigation With his colleagues he was concerned to elucidate the mechanism of increasing salinity of the surface soil in irrigation areas, the possibility of the influence of a rising water-table on it, the difficulties of removing the accumulating salts, and the significance, in connexion with 'water duties', of using extra water to leach them out

During the Second World War, McKenzie-Taylor became director of military engineering research, G H Q India, where he held the rank of brigadier After returning to England on retirement, he had, since 1952, acted as agronomist to Rotary Hoes Ltd

H H NICHOLSON

NEWS and VIEWS

Royal Society Awards Royal Medals

H M THE QUEEN has approved recommendations made by the Council of the Royal Society for the award of the two Royal Medals for 1961 as follows to Sir Wilfrid Le Gros Clark, Dr Lee's professor of anatomy in the University of Oxford, in recognition of his outstanding contributions to neuroanatomy and primate morphology, which he has combined to provide new knowledge of human evolution, to Prof C F Powell, Melville Wills professor of physics in the University of Bristol, in recognition of his pioneering work on the development of photographic emulsion technique in the investigation of cosmic rays and the outstanding results derived therefrom on the elementary particles in cosmic radiation

Experimental Physics in the University of Sussex

Prof K F Smith

DR K F SMITH, at present lecturer in the Cavendish Laboratory, Physics Department, University of Cambridge, has been appointed to the chair of experimental physics in the new University of Sussex at Brighton Prof Smith was born in 1923 and went to Colfe's Grammar School at Lewisham (London) In 1942 he went to Cambridge with a minor scholarship to Sidney Sussex College His studies were interrupted in 1945 by work on atomic energy, first in Canada and then at the Atomic Energy Research Establishment at Harwell In 1948 he returned to Cambridge and began to build an apparatus for measuring nuclear spins, using the molecular-beam method, developed by O Stern and further by I I Rabi, but not previously used in Great Britain He aimed in particular at the study of unstable, that is, radioactive nuclei, of which only very minute quantities can be obtained In subsequent years he and his students developed various ingenious ways of recording the faint trickle of atoms that pass through the severe scrutiny of narrow slits, two inhomogeneous magnetic fields and a radio frequency field which causes the spin of the atom to change direction Research Fellow of Sidney Sussex College since 1950, Senior Exhibitioner in 1952, Dr Smith became a demonstrator in the University of Cambridge in 1953, and lecturer in 1958 He spent a year's sabbatical leave in 1958 as an associate professor at Berkeley, California He will be followed to Brighton by the good wishes of the molecular-beam fraternity everywhere

Iodine-131 in Milk in Britain

RESULTS are now available for measurements, made by the Agricultural Research Council Radiobiological Laboratory, of iodine-131 in milk during the week ending November 11 The method of sampling was the same as that already described (see *Nature*, November 11, p 504) Milk is collected daily from 23 sites in different parts of England, Wales, Scotland and Northern Ireland In addition, on one day in each week country-wide samples are provided by more than 200 depots which together handle more than 40 per cent of the total milk produced throughout the United Kingdom The mean results of the daily samples are shown in Table 1

Table 1

Week	$\mu\mu c$ Iodine-131/litre
October 15–21	114
October 22–28	158
October 29–November 4	127
November 4–11	117

The survey of iodine-131 in milk throughout the United Kingdom has been in progress for 8 weeks and an analysis of the combined results of the daily and country-wide sampling now enables the overall situation to be assessed in terms of the recommendations made by the Medical Research Council It was stated that the acceptable radiation dose would not be exceeded for infants under one year of age, the most susceptible age group of the population, unless the average concentration of iodine-131 in milk rose above 130 $\mu\mu c$/litre over a period of one year, or higher concentrations were maintained for correspondingly shorter periods This recommendation took into account the likely extent of variations in the contamination of local milk supplies The significance of the quantity of iodine-131 which has so far entered milk can thus be assessed by comparing it with that which would give rise to the annual average specified by the Medical Research Council Table 2 shows that in different regions of the country, between 9 and 20 per cent of the specified annual total had been reached on November 11, the country-wide average being 14 per cent

Table 2 SUMMARY OF RESULTS OF DAILY AND COUNTRY-WIDE SAMPLING OF MILK FOR IODINE-131 DURING EIGHT WEEKS, SEPTEMBER 16–NOVEMBER 11

	Zone	Average contamination ($\mu\mu c$/litre)	Percentage of quantity which would give rise to annual average specified by the Medical Research Council
1	Northern England	103	12
2	North-West England	98	12
3	East and East Midland	72	9
4	West Midland	106	13
5	Wales	165	20
6	South and South-East England	94	11
7	Mid-Western England	100	12
8	Far-Western England	133	16
9	Scotland	157	19
10	Northern Ireland	164	19
	Country-wide mean	115	14

The highest values have been found in Wales, Northern Ireland, Scotland and far-western England, but even these would not lead to the annual average specified by the Medical Research Council unless they continued for at least a further seven months or more. Regional differences can result not only from climatic and geographical factors but also from differences in the diet of cattle. The quantity of iodine-131 which they consume depends primarily on the quantity of fresh grass which they eat; thus, recently deposited fission products enter milk less readily when, owing to the onset of winter, cattle are provided with increasing quantities of other foods. In 1958, after the previous series of weapons trials in the Arctic, this effect was marked from the middle of November onwards, and results from Scotland suggest that it is occurring again. It cannot, however, be assumed that the contamination of milk will decrease steadily in the future, because for some weeks after the detonation of nuclear weapons the rate of deposition may vary widely depending on meteorological factors. A careful watch will therefore be maintained so long as appreciable levels of contamination remain.

Paul Instrument Fund Grants

AWARDS of grants by the Paul Instrument Fund Committee have been made as follows: £44,500, with the possibility of an increase to £52,000, to Dr. V. E. Cosslett, University lecturer in physics, University of Cambridge, to design and construct a very high voltage electron microscope and to explore its applications in biological and metallurgical research; £1,000, in supplement of a previous grant, to Prof. D. Gabor, professor of applied electron physics in the Imperial College, University of London, and Dr. D. Jones, for work on the development of an electron interference microscope; £3,500 to Mr. D. W. Hill, research department of anæsthetics, Royal College of Surgeons of England, for the construction of an infrared gas or vapour analyser using interference filters; £2,500 to Dr. N. Kurti, reader in physics and senior research Fellow, Brasenose College, Oxford, for the construction of a nuclear thermometer for use in the micro-degree Kelvin temperature-range; £1,500, in supplement of a previous grant, to Dr. J. H. Sanders, University lecturer and demonstrator in physics, Clarendon Laboratory, Oxford, for the construction of an optical maser. The Paul Instrument Fund Committee, composed of representatives of the Royal Society, the Institute of Physics and the Physical Society and the Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much improved types of physical instruments and apparatus for investigations in pure or applied physical science".

Department of Technical Co-operation

IN a written answer in the House of Commons on November 14, the Secretary for Technical Co-operation stated that of the expenditure on overseas information services, 32 per cent was attributable to the British Council, 35 per cent to the British Broadcasting Corporation, 13 per cent to the Central Office of Information and 20 per cent to overseas departments. The Department had taken over 87 administrative and advisory staff from other Departments, including 31 from one of the Overseas Departments, 155 executive staff, and 306 ancillary staff. With four exceptions, the staff had been previously employed on work which had been transferred with them. He was now considering how the Department's ability to help with advice on the economic aspects of development could be strengthened.

Technical Colleges and Schools in Britain

IN reply to a question in the House of Commons on November 16 regarding the number of technical colleges and schools in Great Britain, the Minister of Education, Sir David Eccles, said that in England and Wales there were 761 grant-aided major establishments, 232 maintained secondary technical schools and 5 direct-grant secondary technical schools. Students in the two latter numbered 97,039 and 838, respectively, in January 1961. In the 1959–60 sessions, 112,768 students attended full-time courses in the major establishments, 10,038 sandwich courses, 501,003 part-time and 784,584 evening courses. In the 92 major establishments in Scotland, there were 12,549 full-time students, 35,609 part-time and 52,696 evening students. Construction is in progress on 126 major projects in England and Wales and 18 in Scotland, and 217 further projects in England and Wales and 25 in Scotland have been approved.

High-flux Reactor at Petten

THE high-flux materials testing reactor at the Petten research centre of the Reactor Centrum Nederland became critical for the first time on November 9. This is the second reactor to become critical at Petten since September 28, 1960, when a low-flux reactor was put into operation. The nuclear part of the high-flux reactor was designed and delivered by the U.S. firm of Allis-Chalmers Manufacturing Company, the remaining part having been built in co-operation with several Dutch companies. Most components, also those delivered by Allis-Chalmers, were manufactured by Dutch industries. The reactor, which is essentially similar to the U.S. Oak Ridge research reactor, is intended for the testing of materials. The neutron beams emitted by the reactor can also be used for carrying out neutron physics research and for the production of radioisotopes. During the forthcoming months the reactor will be operated at low power. Afterwards the power will be gradually increased up to the maximum level of 20,000 kW. It is expected that this level will be reached in the spring of 1962. In the meantime, the reactor vessel, in which the actual core of the reactor is situated, will be replaced by a new one, which has been manufactured in the United Kingdom.

Digital Computation at King's College, Newcastle upon Tyne

A NEW automatic digital computer has been ordered by King's College, Newcastle upon Tyne, to replace the *Pegasus* computer in the Computing Laboratory. The new computing system is based on the *KDF* 9 machine manufactured by the English Electric Company. A grant towards the cost of the machine has been promised by the University Grants Committee, while the balance remains to be found by the College. The new system is capable of very high speeds of calculation and has facilities for storing large quantities of information on magnetic tape. Results in both numerical and alphabetical form can be printed at speeds up to 600 lines per min. On some problems the new machine will operate at about one hundred times as fast as the existing machine, and will greatly assist many research projects in both pure and applied science not only for the University but also for industry It will permit also the training of many students in the techniques and applications of automatic computing At the present time, computing systems are being ordered in increasing quantities for both scientific and commercial applications, and the machines are being built faster than people are being taught how to use them There is thus great need for enlarged training facilities of the kind the Computing Laboratory can provide

National Research Council of Canada

The recently published forty-fourth annual report of the National Research Council of Canada outlines the scope of work carried out during 1960–61, including the provision of 7 1 million dollars to support pure research in the universities (including 775 grants, 550 scholarships and fellowships) and an additional 2 3 million dollars through the Medical Research Council (Pp 48 N R C 6322 Ottawa Queen's Printer, 1961) The National Research Council employs 670 scientific research staff (including 130 postdoctorate fellows) and 953 personnel, and operates five laboratory divisions covering the fields of applied biology, applied chemistry, pure chemistry, applied physics and pure physics, and also controls the four engineering divisions, including building research, mechanical engineering, the National Aeronautical Establishment, and radio and electrical engineering as well as two regional laboratories, one at Halifax and the other in Saskatoon During 1960–61 it sponsored thirty-six associate committees, operating in such diverse fields as the control of hospital infections, experimental psychology, plant breeding, radio science, and soil and snow mechanics, and dealt with 14,500 technical inquiries from Canadian industries The outstanding event of the year was the establishment of the Medical Research Council as an autonomous body associated with the National Research Council The report also includes the annual reports of the Medical Research Council and Canadian Patents and Development, Ltd

The *Review of the National Research Council*, Canada, for 1961 (Pp 377 NRC No. 6421. Ottawa National Research Council, 1961. 75 cents), describes the work of the Council to March 31, 1961, and besides reports of the directors of divisions and heads of sections includes accounts of the work of the Council's committees and the first review of the work of the Medical Research Council, 1960–61 Lists of publications during the period are appended to the several reports of divisions, etc, and with the directory of staff and list of staff serving on outside organizations the *Review* is a comprehensive reference work on the two Research Councils, supplementing the information given in the annual report for the period and in the report on university support

Safety in Mines Research

The annual report of the Safety in Mines Research Establishment of the Ministry of Power for 1960 gives a concise yet easily readable account of the wide range of work undertaken by the Establishment (London H M S O Pp 72 + 4 plates. 5s net) Within the main body of the report sections are devoted to explosives and blasting devices, explosion hazard, fire hazard, rescue apparatus, engineering and metallurgical research, dust measurement and the pneumoconiosis hazard, investigation of mining incidents, examination of equipment after mine service and testing services. Special attention is being paid in the field of coal dust explosions to the use of stone-dust barriers and a full-scale explosion gallery is to be built at the Buxton laboratories Most coal dust explosions underground are initiated by the ignition of firedamp, accordingly, the work on layering of firedamp and its accumulation has been extended together with an examination of preventive and remedial measures At the same time research on the frictional ignition of gas, particularly between metals and rock, is in progress Ignitions of gas due to shot-firing are very few compared with the tens of millions fired each year; but such ignitions are always serious, present work in this field is concerned with the safety of millisecond-delay firing and with improved methods of testing explosives Much of the work described in the report will be of interest to many fields of industry other than the coal industry not only in connexion with explosion and fire hazards but also in connexion with breathing apparatus, engineering and metallurgical research, dust measurement and pneumoconiosis

Wool Research Colloquia in Australia

A new series of one-day meetings has been inaugurated in Australia to discuss particular aspects of wool research. They are being organized by the Commonwealth Scientific and Industrial Research Organization Wool Research Laboratories, and invitations are extended to those research workers in university and C S I R O laboratories who are working on the subject under consideration Wool Research Colloquium No 1, which was held at the Division of Protein Chemistry, C S I R O, Parkville, Victoria, on September 20, was convened by Dr R D B Fraser Wool structure was considered at this meeting under the headings of molecular structure, chemical structure, biosynthesis and physical properties and structure. Wool research scientists from several States of the Commonwealth attended the meeting Prof H Fraenkel-Conrat, of the Virus Laboratory, University of California, who had been in Melbourne as guest lecturer during a series of lectures in protein chemistry, and Mr I K Walker, director of the Dominion Chemical Laboratory, Wellington, New Zealand, were guests at the Colloquium These meetings will be a permanent feature and they are intended to provide specialist discussions on major aspects of the C S I R O wool research programme

Research and Education in Physics

An international seminar for research and education in physics, co-sponsored by the International Atomic Energy Agency, the United Nations Educational, Scientific and Cultural Organization and the Central Committee for Swedish Technical Assistance, is to be held as a one-year course at the Institute of Physics, Uppsala, during September 1, 1962–July 1, 1963. The aim of the seminar is essentially to provide possibilities for individual participation in qualified experimental research work in one of various fields of physics (for example, solid-state physics, X-ray physics, nuclear physics, atomic physics, etc) under the guidance of experienced scientists An introductory course in the operation of, and the coding for, a modern computer, IBM 1620, will be given The seminar will be open to non-European students and scientists, mainly from developing countries, who are working in the above-mentioned subjects and who are connected with the teaching and/or research of a university or national laboratory, and who are not less than twenty years and not more than forty years of age Application forms and further information can be obtained from the International Seminar, Institute of Physics, University of Uppsala, Uppsala, Sweden

University News

Belfast

THE following appointments to lectureships have been announced Dr R H J Sellin (civil engineering), F J Smith (applied digital mathematics computing), Dr Uno Opic (applied mathematics)

Bristol

THE following appointments to lectureships have been announced C Andrew (mechanical engineering), Dr R Binks (organic chemistry), J S E David (veterinary surgery—diseases of reproduction), Dr R P Mercier (theoretical physics), Dr J G C Milne (physics), D B Peacock (bacteriology)

Cambridge

THE following elections at Churchill College have been made *Fellowships*, J A Pateman, University lecturer in genetics, and C K Phillips, deputy treasurer of the University, *Junior Research Fellowship*, J S Gibson, of the University of Sheffield, in genetics, *Extraordinary Fellowship*, Prof Jacques Barzun, professor of history, Faculty of Political Science, provost of Columbia University for 1962–63, and Prof Kenneth J Arrow, professor of economics and statistics, Stanford University, for 1963–64, *Overseas Fellowship*, Dr P W Anderson, of the Bell Telephone Laboratories

Ibadan

THE Calendar 1961–62 of the University College, Ibadan, Nigeria, lists the officers, standing committees, principal standing boards and committees of the Senate, honorary associates and the staff of the College (Pp 110 Ibadan The University College, 1961) Besides particulars of entrance regulations, courses of study, scholarships and prizes, there are notes on the Department of Extra-Mural Studies, Institute of Education, Institute of Child Health, and the Nigerian Institute of Social and Economic Research A list of graduates for 1961 is also included

London

PROF K G DENBIGH, professor of chemical engineering at the Imperial College of Science and Technology, has been appointed to the Courtaulds chair of chemical engineering tenable at that College The following titles have been conferred professor of geography, on Dr W R Mead in respect of his post at University College, professor of organic chemistry, on Dr L N Owen in respect of his post at the Imperial College of Science and Technology, reader in anatomy, on Mr D W James in respect of his post at University College, reader in chemistry, on Dr C A Vernon in respect of his post at University College

Miami

DR CARL H OPPENHEIMER, formerly of the University of Texas Marine Institute at Port Aransas, has been appointed research associate professor at the Institute of Marine Science, University of Miami, where he is at present head of the microbiology group

Announcements

PROF J B S HALDANE, formerly professor of biometry in the University of London and later research professor in the Indian Statistical Institute, from which post he has recently resigned, was awarded this year the Kimber Gold Medal for genetics of the U S National Academy of Sciences He has also received a Premio Feltrinelli for biological sciences of the Accademia dei Lincei, Rome Prof Haldane attended a special meeting during the summer of the Physiological Society held in Oxford to commemorate the centenary of the birth of his father, J S Haldane, and received an honorary doctorate of science from the University He expects to take charge of a small laboratory for research in genetics to be set up by the Council for Scientific and Industrial Research, India

DR LEO L BERANEK, president of Bolt Beranek and Newman, Inc, of Cambridge, Mass, has been presented with the Wallace Clement Sabine Award of the Acoustical Society of America for his "internationally recognized achievements in all phases of architectural acoustics" The Pioneers of Underwater Sound Award has been presented to Dr Albert B Wood, of the Admiralty Research Laboratory in Teddington, Middlesex, "for nearly half a century of original work in physics and for decades of pioneering leadership in underwater sound"

DR F RALPH KOTTER has been appointed chief of the newly established High Voltage Section of the Electricity Division at the National Bureau of Standards, U S Department of Commerce Since 1955, Dr Kotter has been working on standards of inductance and capacitance at the Bureau

DR THOMAS R LAWRENCE has been appointed to the National Bureau of Standards, U S Department of Commerce As a member of the Engineering Metrology Section, Dr Lawrence will investigate the applicability of the helium–neon gaseous optical maser to precision measurements of length

THE Systematics Association is organizing a lecture on "The Systematics of Man", to be delivered by Dr B G Campbell at the British Museum (Natural History) on February 8 Further information can be obtained from Mr Norman Tebble, Systematics Association, British Museum (Natural History), Cromwell Road, London, S W 7

AN international symposium on the growth and development of the lower archegoniate plants will be held in the rooms of the Linnean Society of London, Burlington House, Piccadilly, London, W 1, during April 5–6, 1962 Further information can be obtained from the General Secretary of the Society

ERRATA In the article entitled "The Mechanism of Action of Liver Alcohol Dehydrogenase" in *Nature* of October 7, p 47, the following corrections should be made Table 1 $\varphi_{12} = 0\ 9$ sec μM^2, $\varphi_{12}' = 10{,}500$ sec μM^2, $K_{E,\mathrm{alc}} = 6060\ \mu M$, in Fig 1 2 2 μN LADH in (3), (6) and (7), col 1, line 5 from bottom of p 49, ($pK = 8\ 6$)

DR D B E STROUD, writing in connexion with the article "Mannosyl-D-Glucosamine Hydrochloride Isomers" (*Nature*, 191, 142, 1961), states that the optical rotation $[\alpha]_D^{20} + 55°$ quoted on p 143, three lines from foot of col 2, refers to the original mixture of fractions $A + B$, and not to fraction B

WATER POLLUTION RESEARCH IN GREAT BRITAIN

A FURTHER stage in the development of the Water Pollution Research Laboratory of the Department of Scientific and Industrial Research was marked by two open days at Stevenage on October 11–12, when interested members of the public could see a wide range of work in progress and also inspect the new wing which came into use during the summer

The new west wing, designed by the Ministry of Works, provides an additional floor space of nearly 20,000 sq ft and comprises four pilot-scale laboratories, with several smaller laboratories and offices (Fig 1) One of the pilot-scale laboratories rises through three storeys and the others are two storeys in height, giving adequate headroom for treatment equipment of all kinds The construction is in load-bearing brickwork, which facilitates the fixing and support of apparatus A full range of services is provided, and the keynote is flexibility

The fact that this new wing has become necessary —it is already almost fully occupied—only seven years after the Laboratory moved to Stevenage from its temporary headquarters at Watford is a sign of the increasing need for research into all aspects of the pollution of water Three recent Acts, the Clean Rivers (Estuaries and Tidal Waters) Act, 1960, the Rivers (Prevention of Pollution) Act, 1961, and the Public Health Act, 1961, have extended control over the discharge of wastes into rivers and estuaries, and the field of pollution prevention and control is now a very active one, in which local authorities, river boards and industry are all closely concerned

In order that the work of the Laboratory can be more closely applied in Scotland, an out-station has recently been established at East Kilbride, near Glasgow This station carries out its own local research and can also call on the resources of the main laboratory at Stevenage when necessary

The functions of the Water Pollution Research Laboratory are, broadly, to study and improve methods of treating polluting liquids, including both domestic sewage and trade effluents, and to study the effects of pollution on surface waters The scope and variety of the work involved are so great that only a few examples can be described Two subjects of wide general interest may be mentioned first

The survey of the Thames Estuary, which was started in 1948, is now nearing completion Its primary object was to provide information for the guidance of the Pippard Committee, the report of which is now with the Minister of Housing and Local Government and is expected to be published shortly Analytical records collected by the London County Council during some sixty years, supplemented by detailed surveys made by the Laboratory staff, have been used to study the complex relationships between dissolved oxygen, temperature, pollutional load, freshwater flow and other factors A theory of mixing developed at the Laboratory has enabled predictions to be made of the effect of changes in the pollutional load on the condition of the estuary water It has given good results when applied to changes known to have taken place in the past Fresh problems have presented themselves as the survey has proceeded For example, the role of nitrates as a reserve of oxygen, the rate of nitrification of polluting matter, and the effect of synthetic detergents on the rate of settling of suspended solids have all required special study before the complete picture of conditions in the estuary can be built up

The second subject of general interest is the search for synthetic detergents which can be broken down biologically in sewage treatment works and will not produce the familiar and objectionable foam on rivers During recent years the Laboratory has tested 74 new materials for manufacturers on a repayment basis It has also collaborated in the 'Luton experiment', in which a 'soft', straight-chain detergent, sodium 'Dobane *JN*' sulphonate, has, since 1958, been distributed by the manufacturers in Luton and the surrounding district instead of the normal 'hard' detergent An extensive programme of sampling at Luton sewage treatment works and in the River Lea has shown a reduction of about 40 per cent in the surface-active material entering the river This is rather less than expected on the basis of laboratory experiments, a result which may be due to the unusual method of treatment used at Luton, consisting of high-rate activated sludge treatment followed by high-rate biological filtration. A greater reduction of the new material has been observed at some other sewage works in the area, and this disparity between different methods of treatment is being further examined in the Laboratory

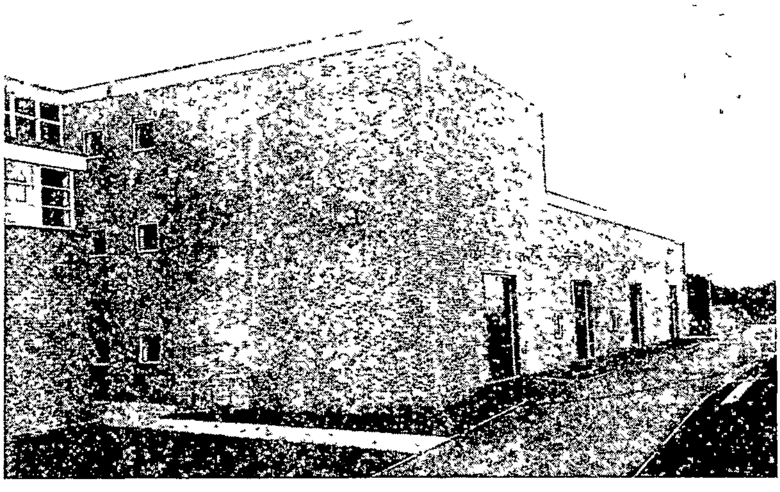

Fig 1 The Water Pollution Research Laboratory Pilot-scale laboratories in the new west wing

Treatment of Sewage and Industrial Wastes

Little information has hitherto been available on the relative merits of the various filter media used in the biological filtration of sewage Since April 1959 a portion of the Stevenage domestic sewage has been treated on a battery of eight small filters filled with two different sizes (nominally about 1 in and 2½ in) of four different media (clinker, blast-furnace slag, broken rock and rounded gravel) With the exception of the gravel which, in the smaller size, gave some ponding trouble during last winter, the smaller media have consistently produced better effluents than the larger media The media with the larger surface area per unit bulk volume, namely, the clinker and slag, gave better results than those of more regular shape, namely, the broken rock and rounded gravel These relative efficiencies of treatment applied not only to the removal of biochemical oxygen demand but also to the reduction in bacterial counts

Investigations into the activated sludge process have been principally concerned with the efficiencies of various methods of aeration The work has suggested ways in which the efficiencies (on a basis of oxygen put into solution per unit of power supplied) accepted in normal sewage treatment practice could be considerably improved by such means as altering the geometry of the aeration tanks Whether the gain in efficiency would be outweighed by other disadvantages such as increased capital cost would depend on local conditions

Interesting fundamental studies have been started on the kinetics of the activated sludge process, to determine the relative importance of the method and intensity of aeration, the level of dissolved oxygen and the concentration of sludge maintained in the tanks, the degree of turbulence and longitudinal mixing and other variables

There is an increasing demand for investigations into methods of pre-treating specific industrial wastes, and this work is done by the Laboratory on repayment Recent and current work of this nature includes the removal of ferrocyanide from engineering wastes, the electrolytic oxidation of cyanide, the bacterial oxidation of thiocyanates, the use of beds of calcined magnesite to neutralize acid wastes, and the treatment of washings from cattle sheds and other farm premises—this last being a growing problem which sometimes causes difficulty at small sewage works

River Pollution

A large part of the work on rivers is devoted to assessing the relative effects of surface aeration, photosynthesis and plant respiration on the oxygen balance As a positive step towards increasing the oxygen content of a polluted river, experiments are being performed on air entrainment in a Venturi tube, which could be inserted in an effluent pipe near the point of discharge to a river The method is simple and, on the laboratory scale, has shown promising results

Work on the toxicity to fish of ammonia and other chemicals has continued, and the effects of mixtures of toxic substances are now being examined

Measurement Techniques

It is inevitable that a laboratory such as this should from time to time find that existing standard methods of analysis and measurement are unsuited to its needs in many specialized lines A valuable part of its work is therefore the improvement of old methods and the development of new Among its contributions in this way are the improvement of established methods for determining nitrites and nitrates, the introduction of new techniques for assessing organic carbon and for the separation of radioactive strontium and barium, and the design of automatic sampling equipment for sewage, and recorders for dissolved oxygen and suspended solids.

The work of the Water Pollution Research Laboratory is thus seen to be a judicious combination of fundamental investigation and practical application for the benefit of the man on the job On the impressive evidence put forward during the open days, it seems to be doing this work very well indeed

F E Bruce

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION, AUSTRALIA

THE thirteenth annual report of the Commonwealth of Australia Scientific and Industrial Research Organization for the year ended June 30, 1961, besides being a general review and a brief survey of some of the more important developments arising during the year out of the research being carried out by the Organization, includes a list of papers published during the year and details of the membership of the Advisory Council, the State Committees and staff[*] Total expenditure amounted to £9,603,963 and the Treasury appropriation to £7,571,104, of which £1,058,246 was in the animal research laboratories, £886,518 on plant research, £334,613 on food preservation, £396,600 on forest products, £856,192 on the chemical research laboratories, £246,683 on fisheries and oceanography, £767,705 on the National Standards Laboratory, £451,278 on radio physics, £574,252 on wool research, £280,904 on fuel research, £333,237 on land research and regional survey, £51,700 on research association grants and £95,069 on overseas research studentships While since 1950 the total budget increased from £2 7 million to £9 6 million, the research staff only increased from 750 to 880, and the Executive believes that this increase in staff is quite insufficient

The giant radio telescope being erected at Parkes for the Division of Radiophysics is structurally completed and is in fact now available full time for research The Controlled Environment Research Laboratory is scheduled for completion early in 1962

Among the research developments noted in the review are a new method of stimulating the germination of legume seeds by exposing water-soaked seeds to low concentrations of carbon dioxide, a practical and economic means of controlling posthitis in wethers by implanting under the skin small pellets of the male hormone, testosterone; progress in work on worm parasites of sheep and cattle, and evidence that selection of cattle for their resistance to ticks may be a highly satisfactory means of minimizing losses due to tick infestation Codling moth infestations have been found to depend largely on the larvæ which over-winter in an orchard, and these, in turn, on the amount of cocoon shelter available in the orchard This can be reduced by adequate management, and, if trap bands are provided to which the overwintering individuals are attracted in large numbers and destroyed by special toxic deposits, relatively few insecticidal treatments are needed in the following season Work at Katherine has shown that nitrogen in a form available to plants concentrates just under the soil surface during the dry season and the greatest loss occurs during the wet season, owing to leaching by rain

---

[*] Commonwealth of Australia Thirteenth Annual Report of the Commonwealth Scientific and Industrial Research Organization for the year ending June 30, 1961 Pp iii + 150 (Melbourne Commonwealth Scientific and Industrial Research Organization, 1961)

It has now been demonstrated that when the appropriate fertilizer dressings to overcome deficiences in nitrogen, phosphorus, potassium, sulphur, calcium, zinc and molybdenum are applied to the infertile coastal lowlands of southern Queensland, pastures can be grown on these soils which grow and fatten cattle at stocking-rates of a beast to 1 5 acres, with annual live-weight increases of 300 lb per beast Investigations on the role of elements in plants have shown that manganese deficiency inhibits a reaction involved in the evolution of oxygen during photosynthesis and also that manganese is a constituent of normal chloroplasts Studies on the life-habits of the freshwater snail *Lymnea tomentosa*, which infests grazing lands, have revealed great difficulties in applying effective control measures, as if the population is drastically reduced each surviving snail will harbour so many liver flukes that the end result is much the same Spoilage of dried prunes of high-moisture content has been prevented by hot-filling the prunes into laminate bags

A direct-reading tester for increasing the regain of wool has been developed, consisting of a hot-air blower to dry the wool and a balance which indicates regain directly Evidence has been obtained that substantial numbers of freezing nuclei occur at altitudes of 50,000–60,000 ft, and work has been completed on a recorder, designed to operate for periods up to 12 months, to provide continuous records of water-level in streams, dams or bores for gauging purposes, or of rainfall, temperature, humidity, wind speed or evaporation A process has been devised for production of pure thorium by converting thorium carbide to volatile thorium iodide and depositing thorium metal from this on to a heated surface. A new cyclone elutriator, the 'Cyclosizer', developed for precise separation of solid particles in the subsieve ranges, is based on the stable flow patterns and high centrifugal forces obtainable in hydraulic cyclones of suitable dimensions

A thorough examination has been made of resistance measurements to establish clearly the possible limits of accuracy using both direct and low-frequency alternating current, and fundamental investigations of cell wall organization of the tissue elements of wood and of the pits between them has demonstrated that in hardwoods the initial penetration path is through the vessels and then via the pits to the rays and adjacent fibres or vertical parenchyma In softwoods the path is from tracheid to tracheid, or tracheid to parenchyma, through the pits A notable advance in the metal-staining technique for the electronmicroscopy of wool has revealed further structural details within the microfibrils and a resolution of 1 in 4,000 has been achieved with a mass spectrometer constructed at the Chemical Research Laboratory, while new techniques, involving an optical filter of narrow band-width, have provided photographs showing the velocity distribution in selected areas of the solar chromosphere

SCIENTIFIC RESEARCH IN NEW ZEALAND

THE report of the Department of Scientific and Industrial Research, New Zealand, for the year ended March 31, 1961*, includes the Minister's Statement, the report of the Council of Scientific and Industrial Research and that of the Secretary, while the third annual report of the Ross Dependency Research Committee is appended Lists of publications during the year are given under the respective branches of the Department together with lists of projects in hand.

Expenditure during the year amounted to £1,963,486 net, of which £201,421 was on the Dominion Laboratory, £225,114 on the Dominion Physical Laboratory, £131,777 on the Grasslands Division, £124,885 on the Geophysics Division, £114,532 on the Geological Survey and £111,986 on the Soil Bureau The Council again points out that New Zealand is still lagging behind in the application of science and the scale of research, and her expenditure in 1959–60 of about £3 98 million on scientific work or 0 32 per cent of the gross national produc compares with 2 3 per cent in Britain and 2 7 pe cent in the United States in 1957–58 Professional staff at April 1 was 401 compared with 390 in 1959–60, total staff being 1,121 and 1,067, respectively, and the Secretary refers to a loss of 30 professional staff during the year, overseas, nearly all experienced scientists, although the overall calibre of the Department's staff has substantially improved over the past decade. During the past five years M Sc graduates in physics in New Zealand universities have averaged 10, in chemistry 21 and in mathematics 13, but about half those obtaining first-class honours accept posts overseas and do not return The Secretary stresses the importance of being able to attract scientists of high quality and indicates some of the factors, besides adequate salary, which are important In 1960 the establishment of two senior research fellowships tenable in the Department's laboratories for up to two years was approved and two fellowships have now been awarded The Council is gravely concerned, however, that no action has been taken towards securing the 40–50 increase in staff per annum

* New Zealand Report of the Department of Scientific and Industrial Research for the year ended 31 March, 1961 (H 34) Pp 87 (Wellington Government Printer, 1961)

over the next five years which is required to implement fully the Department's present programme of work

After discussions with the University Research Committee and the chairman of the new University Grants Committee the Council proposes to terminate the present type of research grant made to the universities by the Department From the end of the present financial year the Department will sponsor and provide funds for research units in universities in fields of study deemed essential in the national interest, and in which an outstanding man is stationed in the university, and by entering into research contracts with universities Grants to research and allied institutions in 1960–61 amounted to £176,862, of which £33,810 was to universities and agricultural colleges and £91,376 to research associations

The Council's recommendation for the establishment of a new Wool Research Organization as an incorporated research association with an annual income of £100,000, half from the New Zealand Wool Board and half from the Government has been approved, and the new buildings for the Meat Research Institute were completed during the year The Council has decided to continue New Zealand's scientific programme in Antarctica at about its present level (£86,606 in 1960–61), and topographical and geological survey work will be continued until the reconnaissance of the Cape Adare–Beardmore section is complete Some concern is expressed as to the effect of delay in developing the Institute of Nuclear Sciences on the research programme in this field

Points in the research work completed during the year noted in the Secretary's report include the completion of the first volume of the new *Flora of New Zealand*; the high yields now being obtained with Aotca wheat, bred at the Crop Research Division and released in 1957, the marked difference in the distribution of radioactive selenium in plants, the variation of the nitrate-levels and of sodium, potassium, calcium, manganese, aluminium, copper, titanium, iron, zinc, sulphate and phosphate in rye-grass plants, and the study of the systematics and taxonomy of bacterial plant pathogens

The Fruit Research Division's apple-variety collection has led to the selection of the Canadian variety Spartan and a local seedling, Red Fresca for extensive commercial trial, and satisfactory drying of tobacco leaf has been obtained by two methods which enable a kiln to be loaded with much less labour and permit the use of smaller kilns A study has been made of the Adelie penguins breeding at Cape Royds, Ross Island, and a set of 54 soils selected representing a range of New Zealand soils for agricultural, forestry and highway purposes is being examined comprehensively by chemical physical and biological tests

An intensive mineralogical study of volcanic ash showers has been commenced, and the four-mile geological map project commenced in 1956 to be completed in 1964 has already indicated areas meriting more detailed examination. A rugged tester, in which the sample is dried for 5 min in hot air and weighed on scales calibrated directly in water content (corrected for buoyancy) has been developed by the Dominion Laboratory, and 20 of these machines are now in use in scouring works and freezing works throughout New Zealand for controlling the drying of wool A fœtal heart-rate recorder has been constructed using a heart-sound pick-up which delivers this conglomeration of sounds to a system specially designed to deal with a fœtal pulse which may be mostly even below the level of background noise Investigations of the variation in the essential oil derived from samples of *Pinus radiata* have been initiated, and an instrument developed for rapidly and accurately determining the density of a wood sample taken from a living tree, utilizing a very narrow beam of beta-radiation from a strontium-90 source A novel type of navigation light for marking narrow channels has been developed which can be used when the configuration of the land in line with the channel will not permit the use of more than one light. An emergency wheat-testing service provided by the Wheat Research Institute avoided substantial loss during the 1961 wheat harvest A survey of currents in McCurdo Sound established that at least in summer there is a definite movement of water towards the Antarctic Ice Shelf

FOOT-AND-MOUTH DISEASE

In a report issued by the Research Institute (Animal Virus Diseases), Pirbright, Surrey*, the director, Dr I A Galloway, describes the investigations made into foot-and-mouth and related virus diseases over the past five years

The research programme of the Institute is considered in relation to foot-and-mouth disease in Britain, and, in turn, as a world problem In Britain, periods of relative freedom from the disease (or at least of low incidence) are interrupted by times when as many as 200 farms may become infected in one month These periods of higher incidence do not generally last more than three or four months, and the number of animals involved in relation to the animal population of the country remains less than half of 1 per cent It is generally agreed that a vaccination programme against the disease in a country where it is endemic is unlikely to reduce the incidence much below this figure If, therefore, the disease were allowed to become endemic in Britain, and vaccination were decided on, the ultimate goal which could reasonably be achieved would be an incidence equivalent to that which now obtains At that point, a slaughter policy would undoubtedly be invoked to attempt to achieve eradication of the disease If the situation in the European countries is considered, it is seen that, in spite of an increasing extension of vaccination since the 1951–52 epidemic, the incidence of the disease, though greatly reduced, is still somewhat higher than in Britain Some countries are applying, and others considering, limited slaughter of infected animals as a further step towards eradicating the disease Outside Europe, in endemic areas, effective control of the disease is still some way off, and it is here perhaps that the new improved vaccines have the greatest part to play, if the cost of the vaccination campaign can be reduced and the efficiency of the vaccine increased Assistance in reduction of the incidence of the disease elsewhere than in Britain is at present the greatest contribution which can be made towards the control of the disease within the country

---

* Research Institute (Animal Virus Diseases), Pirbright Report for the years 1956–1960 Pp 52 (Pirbright, Surrey Research Institute (Animal Virus Diseases), 1961) 2s. 6d

A considerable proportion of the research effort at Pirbright has always been directed at improved methods of immunization against the disease. The period under review has seen a new bias on work on immunization The development of live modified strain vaccines received a new impetus by the demonstration by Skinner in 1951 of the possibility of infecting unweaned mice and, in 1954, of passaging virus in day-old chicks and chick embryos Serial transfers, repeated sometimes many hundreds of times, have the effect of reducing the capacity of the virus to produce visible signs of the disease in the cattle inoculated By multiplying in the animal, however, the virus would stimulate the defence mechanism of the host and so produce a solid long-lasting immunity Such vaccines are used in many other diseases, for example, in rinderpest, rabies, African horse sickness, blue tongue, and in yellow fever and also in smallpox in man Workers developing such strains aim at the point at which the virus will 'infect' the animal but produce no clinical signs The yellow fever vaccine inoculated in man is an example of a live virus vaccine which has reached this point With most live vaccines, the ideal is not attained, and a compromise between slight infectivity in the sense of producing the clinical disease on one hand, and a capability which falls short of the maximum in producing immunity on the other, has to be accepted This has been true in developing the strains in foot-and-mouth disease and the problem has been made more difficult by the demonstration that not all strains become attenuated or lose virulence at the same rate On the other hand, there has been little indication of difficulty in some other ways, for example, there has been no restoration of virulence and no spread to normal animals in contact with those vaccinated Limited experiments on pregnant animals have indicated no unfortunate sequelæ, and young animals have been successfully vaccinated.

The variation in behaviour of viruses has made the development of suitable strains for each of the seven types of virus now known a complicated operation, especially when several different strains of one type have had to be developed to explore the possibilities of different methods of attenuation Nevertheless, strains of six of the seven types have reached the point at which tests for non-infectivity in cattle have been sufficiently encouraging to warrant investigations on the immunity produced These tests at Pirbright have now involved approximately 2,000 animals

The qualified successes obtained under experimental conditions at Pirbright led to the next phase in development of these strains Since the step from the laboratory to field conditions might not be without risk, it was considered that first trials outside the laboratory should be conducted in areas where the disease was endemic The Institute has had the willing and enthusiastic co-operation of the Governments of countries in South and East Africa in a series of trials These experiments have indicated the potential usefulness of suitable strains in such animal populations while, at the same time, bringing to light many of the suspected difficulties inseparable from immunization of a mixed population with possible previous experience of the disease Some of these experiments, notably those in South Africa, have involved tests of live attenuated vaccine on a scale which has not been undertaken with any other agent of this type, in respect of severe challenge with fully virulent material Even under these conditions, 70 per cent protection was obtained and subsequent use of the vaccine in an infected area resulted in an incidence of less than 1 per cent on vaccinated farms, while, on unvaccinated farms, the incidence was between 60 and 70 per cent These observations are essentially preliminary, many problems require investigation

The problem of the use of inactivated vaccines has not been neglected Frenkel-type vaccine in which virus is grown in culture of cattle tongue epithelium, adsorbed on aluminium hydroxide and inactivated with formalin and mild heat, has been a useful agent and will continue to play a most important part in the control of the disease as it has done in Europe and. to some extent, in South America Extensive tests of this type of vaccine have been carried out at Pirbright and several large batches have been prepared and tested for safety and potency Other possible sources of tissue in which virus may be grown, such as kidney, are being investigated, since kidneys present a more easily obtainable source of tissue than cattle tongue epithelium

Foot-and-mouth disease must be considered as a world problem Part of the work at Pirbright, therefore, has been directed towards the assessment of the world situation, particularly in regard to the prevalence of the disease and the distribution of the immunological types of virus Earlier reports have referred to the discovery at Pirbright of four new types—*S A T* 1, *S A T*. 2 and *S A T*. 3 from Africa, and Asia 1 in many countries in Asia In the past twelve years considerable progress has been made in determining the broad outlines of type distribution. The international importance of this work was recognized when, in 1958, the Institute was nominated by the Food and Agriculture Organization of the United Nations to undertake the functions of World Reference Laboratory for Foot-and-Mouth Disease

APPLIED GEOGRAPHY

THE application of geography to the study of a wide range of problems has made remarkable progress in recent years, partly during, and partly because of, the Second World War Geography made a substantial contribution to the British War effort both in the planning of campaigns and in the reorganization of the nation's economy, and since the War geographers have been active in the field of planning Some of the fruits of these efforts can now be seen in the increase in the number of geographers who act as advisers in various fields, ranging from problems of conservation to aspects of medical geography there is also the evidence of the results achieved by those who have been largely employed in the study of the application of geography in Britain to national, regional and county affairs during recent years

At the recent meeting of the British Association for the Advancement of Science a whole morning was devoted, largely by the geographers of Section E, to the planning problems of Britain and to those of East Anglia in particular The future administrative organization of Norfolk and Suffolk is at the moment under review by the Boundary Commission, and during the course of the meeting geographers saw, in the field, the significance of the desire of the rapidly growing and increasingly industrialized city of Norwich to expand into its adjoining county areas Others were shown the changing landscape of Thetford, where residential and industrial developments are designed to absorb part of the overspill of Greater London

Among the speakers in the planning symposium were Mr J R. James, deputy chief planner, Ministry of Housing and Local Government, and the principal research officer of the Ministry, Dr E C Willatts, who introduced a new map, at the scale of 10 miles to the inch, showing the major post-war developments in England and Wales that have resulted from, or are affecting, land planning[1] These developments, including the establishment of National Parks, the building of electrical and nuclear power stations, the construction of motorways, the creation of 'new towns' and the extension of other towns, are indicative of both the scale and scope of post-war changes They show, too, how the regional geography of Britain is in process of being transformed by the technological revolution which, in its geographical aspects, was the subject of Prof S. H. Beaver's presidential address to Section E [2]

In the siting of many of these new developments geographers have sometimes played a significant part An assessment of the scope of geographical inquiry and of the fields in which geographers are capable of making important contributions was made by Prof L. Dudley Stamp in a small book, published in 1960, *Applied Geography*[3] Such a book could have had no better author than Prof Stamp in view of his own great efforts in many of the fields of which he writes. these activities have included the Land Utilisation Survey of Britain, carried through under his direction during the 'thirties, a particularly difficult and trying period for British agriculture[4]; the investigations of the Scott Committee, of which he was vice-chairman, into the use of rural land in Great Britain[5], and his later work as an adviser to the Minister of Agriculture on these problems, his initiative in establishing an organization for a World Land Use Survey under the auspices of the International Geographical Union[6], and his work on the geographical background of many new developments oversea both within and outside the tropics

Some of Prof Stamp's topics have been further discussed by other geographers in the recently issued proceedings of the Anglo-Polish seminar held in Nieborów, Poland, in September 1959, and attended by twelve British and seventeen Polish geographers The volume, *Problems of Applied Geography*, has been published in Warsaw by the Institute of Geography of the Polish Academy of Sciences, which organized the seminar in collaboration with the Institute of British Geographers, with the generous support of Unesco and of the British Council limited supplies of the volume are available for sale in Britain[7] The seminar, like that organized a year later for the exchange of views between American and Polish geographers[8], included a series of papers—six British and five Polish—which served as a basis for discussions between the delegations and was followed by a comprehensive tour of both agricultural and industrial areas of Poland

While most of the six British papers have nothing strikingly original about them, they form a valuable and up-to-date summary of the special problems of Britain to-day as seen by a group of geographers As with the Polish delegation, the British team emphasized the achievements and experience of the theory and practice of planning in its own country, while suggesting that many of its conclusions are of use to all concerned in the application of geography to the study of physical, social and economic problems in contemporary society M J Wise's paper outlines the basic problems of national planning in Britain, including the optimum use of resources, the redevelopment of the older industrial areas, the restriction of the growth of conurbations, and the regulation of population movements, and A A L Caesar shows how these problems vary between regions. H C K Henderson describes the basis of the pre-war Land Utilisation Survey of Britain and indicates how its work has been used in the planning of agricultural land use S H Beaver describes the reclamation of industrial waste-land for agricultural and other purposes, illustrating his paper by a series of carefully chosen examples he shows that the area of land in Britain that cannot be reclaimed—less than 1,700 acres a year—is minute compared with the loss of agricultural land to urban development It is this continuing urban encroachment on the countryside that A. E. Smailes in his paper on perhaps the most distinctive feature of British economy and society—the urbanization of Britain—sees as the crux of the physical planning problem of Britain to-day Finally, K. C Edwards, who, as president of the Institute of British Geographers, was leader of the delegation, discusses the 'new towns' of Britain, the results of which, he finds, though "modest in scale and often despairingly slow in realization, at least encouraging"

The Polish contributions have special value because so little information is easily available about modern Poland, certainly in English They have been deliberately designed to match the British papers thus the importance in Poland of regional planning, land use and urban geography are discussed by K Dziewoński, J Kostrowicki and L Kosiński respectively The two other Polish essays are of a very different type, describing the preparation of a geomorphological and hydrographic map and an investigation of local climate their inclusion in the symposium suggests that there is in Poland a greater appreciation of the significance of such detailed and specialized studies in practical affairs than has so far been the case in Great Britain, where research of this nature would, to most administrators and planners, seem not only academic but even irrelevant

But what will strike readers of this volume most forcibly will be the fundamental contrasts between the British and Polish attitudes towards planning and between the nature and scope of the planning envisaged for the two countries In Britain the problems are those of adjustment and reconciliation rather than those of development—the transformation of the population pattern and economic organization developed in one industrial age to what is required in another, and greatly different, age of new and rapidly advancing technology Poland is concerned with the fundamental development problems that call for comprehensive and large-scale regional planning as a basis for the reconstruction and expansion of the national economy, and Dziewoński's paper shows that the methods and results of geographical research in Poland have exerted very considerable influence on the methods and results of planning For this there is not, and probably never will be, any exact British parallel, but Polish experience does heavily underline the diversity of the ways in which the work of geographers can be used for the nation's good, if they are given the opportunity and the encouragement

International seminars of this type broaden the minds of those participating and at the same time help to create deeper understanding and friendship, while the circulation of the report of the proceedings will be of lasting value to all who are interested in applied geography and who are concerned that it should have the closest possible connexion with life and society.

GAS CHROMATOGRAPHY IN MEDICAL RESEARCH

THE Gas Chromatography Discussion Group of the Institute of Petroleum held an informal symposium on September 26, at the Royal College of Surgeons of England in London

In welcoming the members of the Group, Prof R F Woolmer, on behalf of the President and Council, explained that, apart from surgery, the College research and teaching also covered such associated fields as physiology, biochemistry, dental science and anæsthetics It was appropriate that a symposium concerned mainly with the aspects of gas chromatography in medical research should be held at the College, as they believed in co-operation and a full exchange of ideas with other workers

In the opening paper, Dr A T James described the development and operation of a simple detector for the continuous automatic determination of the radioactivity of carbon-14 and tritium Attention had been directed to automatic determination because of the obvious disadvantages of the previously used discontinuous methods Problems of stability at column temperatures as high as 200° C had led to combustion of the eluted material to carbon dioxide and water, and the measurement of the radioactivity at room temperature The detector consisted of a $4 \times \frac{1}{2}$ in copper tube, plated internally and having a central tungsten wire electrode Rhodium plating reduced the tailing exhibited by tritiated materials Argon or helium was used as carrier gas, and carbon dioxide was bled into the feed to the detector to give a concentration of approximately 5 per cent Chromatograms obtained with conventional detectors and the radioactivity detector were shown to superimpose extremely well An integrated record could also be produced

The next paper, on gas-liquid radiochromatography, by Dr S Popják, confirmed the disadvantages of discontinuous procedures for radioactivity measurements The advantages of continuous monitoring over fraction collection had been evident over a period of three years using a scintillation counter In the method described, carrier gas and eluted fractions were passed through a liquid scintillator in a specially designed apparatus, and the radioactivity measured by scintillation counting Two isotopes could be measured simultaneously Full details of the construction of the apparatus, its method of operation and the associated electronic circuitry were given. A stepped record superimposed well on chromatograms obtained with a gas density balance The efficiency of counting was of the order of 40–50 per cent for carbon-14 compounds, and 15–21 per cent for tritiated compounds

Under the title of "Peak Symmetry in Gas-Solid Chromatography", Mr. C G Scott described recent work concerned with the properties of two active solid systems giving symmetrical elution peaks for hydrocarbons at column temperatures below the boiling point of the eluted component When alumina is modified with sodium hydroxide, the energy of adsorption decreases to a constant value, at which stage symmetrical elution peaks are obtained Such peaks can also be obtained from columns packed with solid organic crystals, although, to increase surface area and so reduce column lengths, the compounds are best deposited on 'Celite' It had been found that heats of adsorption were of the same numerical magnitude as the heats of vaporization Entropies of adsorption were calculated for *n*-heptane, benzene, iso-octane and *cyclo*hexane, and values obtained for the first two compared with those obtained by Kemball for adsorption on mercury

Mr D W Hill and Dr R P W. Scott described recent developments in the design of compact cathode-ray tube gas chromatographs Apart from the high speed of analysis for vapours containing anæsthetics, the apparatus should be compact for easy transport and use in an operating theatre, and be capable of giving rapid repetitive results The instrument was designed around a 6-in square, long-persistence tube having a 20–30 sec scan, and contained its own pump An additional port in the sample injection system allowed a 100 1 gas dilution without the high losses of argon given by 'splitter systems' The micro argon detector had been modified to reduce the effects of electron capture so that the strongly electron-capturing halothane (2-bromo-2-chloro-1,1,1-trifluoroethane) gave a positive peak Column packings for the separation of typical anæsthetic mixtures were mentioned The quantitative response of the argon detector was dependent on temperature, and therefore the use of a thermostat or compensation was necessary A simple thermistor compensator unit was described

Dr R A Butler presented a paper entitled "Parts Per Million and All That" in which he first described his work on anæsthetics, indicating the importance of knowing the concentration of anæsthetics in tissue, the rate of its elimination from the tissue, and equilibrium values of the various substances used He queried the accuracy of calibration standards made from volatile substances, and consequently the accuracy of a detector calibration using such standards He felt that some absolute figures often quoted in papers were at the least rather optimistic, and his paper was obviously designed to stimulate a discussion on the quantitative aspects of gas chromatography It was unfortunate and disappointing that it failed to do so

A contribution by Dr T R Phillips described how, during the analysis of Arcton 12 (dichlorodifluoromethane) in Arcton 11 (monochlorotrifluoromethane), the calibration of the apparatus had to be carried out with synthetic mixtures of the substances and the samples taken at a fixed pressure The sensitivity of the apparatus for Arcton 12 expressed as peak-height/partial pressure was shown to vary with the total pressure of the sample and with the partial pressure of Arcton 11 It was thought that this effect could occur in other systems where a small amount of a weakly retained substance was being analysed in the presence of excess of a more strongly retained one Dr Phillips's suggestion that the effect would not be observed if integration of the peak were used instead of the measurement of peak height was confirmed by other contributors to the discussion

The concluding paper on electron capture was given by Mr N L Gregory He described a detector to which a potential of only 10–20 V was applied and which utilized recombination effects to measure compounds having an affinity for free electrons It was extremely sensitive to halogenated compounds, a typical application being to the detection and determination of insecticides in foodstuffs Another application was to the determination of tetraethyl lead in gasoline, there being no response to the hydrocarbons present Apart from halogenated compounds, polycyclic aromatic hydrocarbons, unsaturated fatty-acid esters and quinones were also good electron acceptors The possibility of the affinity of organic compounds for free electrons in biochemical processes was mentioned

Members of the Group were also privileged to view apparatus, watch demonstrations, and discuss gas chromatographic techniques with workers in various departments of the College, and also in the adjoining Nuffield College of Surgical Sciences This was much appreciated by those present.

INDUSTRIAL TRAINING IN EUROPE

SPEAKERS from Belgium, Holland, Sweden and Switzerland joined colleagues from Britain at the annual conference of the British Association for Commercial and Industrial Education which was held at the University of Nottingham during September 14–16, when an examination was made of education and training on the continent of Europe, with particular reference to the effects of economic integration The theme of the conference is of special significance since free movement of labour among Common Market countries may lead to standardization of systems of education and training, or at least a levelling up of standards

One common thread ran through all the papers —the need to direct more attention to general education in modern schemes of training All the countries present are now beginning to examine their training systems from this point of view

Among the contributors were Monsieur R Grandbois, inspector-general of the French Ministry of Education, who stated that all differences concerning apprenticeships are a consequence of the past They are the result of local habits and customs ; they represent the embodiment of a way of life, the outcome of an evolution both social and administrative. All the similarities are either a consequence of the present or a result of the pressure of things to come. The various systems of apprenticeship have evolved slowly to their present-day form and crystallized behind innumerable frontiers and in confined surroundings, but they are now and will henceforth be subjected to influences for which barriers and remoteness do not exist It can be assumed that the apprentices of to-morrow will have to be educated in much the same way whatever the country to which they belong

Monsieur G C M Hardebeck, secretary of the Bemetal Foundation in Holland, believes that more attention must be directed to general education because it is our responsibility not only to give young people the necessary technical training but also to prepare them to live in a democracy

In his paper, Mr H A Warren, principal of the South-East London Technical College, explained how in Great Britain at a time in the 1930's, when thousands of man-hours were being idled away in unemployment, the young apprentice was asked to work 48 hours a week and in addition, three evenings at college and two more on homework A few million pounds extra expenditure on day release at that time would have meant that Britain to-day would no longer be suffering from a lack of skilled man-power Warren suggested that the wholly evening course, except for recreation or for advanced refresher course studies, is as out of date as the steam locomotive ; despite this, Britain has the administrative arrangements which, to meet the challenge of the changing nature of skill, stand out as far superior to anything in continental Europe "Nowhere in Western Europe is the sandwich course at the C A T [college of advanced technology] level and standard growing to full and recognized stature as it is in Britain"

The pattern of industrial education might have been greatly strengthened had the City and Guilds of London Institute been entrusted also with the General Certificate course at least up to the Ordinary Level of the General Certificate of Education

The British system is weak because of its lack of incentive Since no end-of-apprenticeship tests are insisted on, the studies for apprentices in a technical college are voluntary both in the sense of attendance, and in the sense of acquiring a qualification When, in addition, little recognition will accrue in wages or promotion, the student not unreasonably asks himself why he is pursuing his studies

Prof G Dunand of the International Labour Organization showed how economic mutual penetration has been practised in Europe on a minor scale for centuries For such exchanges it was accepted and convenient to use mainly one language, Latin, and later French, and more recently English, and also German in Eastern Europe The universal use of French or English for European relations has, however, been increasingly questioned since language has become an essential element of conscious nationhood and indeed nationalism Nowadays, supremacy would not readily be granted to the language of any one of the great powers, as, for example, English or Russian. Hence the multiplication, in particular since 1919, of bilingual treaties and multi-lingual international conferences, which have given birth to the profession of conference interpreter and to an extraordinary development of translation for international relations

From this historical review, Dr O G. Pickard, principal of the Ealing Technical College and School of Art posed the question. "Do we then ask the schools to devote less attention to French and take up other languages in its place ?" This has been tried, during the interim period of the two World Wars there was a determined attempt to introduce a great deal of Spanish to English schools for commercial reasons in place of French The immediate result of this attempt was to antagonize the teachers of French all over Britain, who clearly saw their vested interest in the teaching of this language threatened by the proposals to introduce Spanish in its place

So far as the schools are concerned, the question is "whether a third foreign language should find a place in the school curriculum so that it might be possible for school children to learn say, French, German and Russian, or French, Spanish and Swedish, as a normal practice during their school careers With the growing close association between the economy of Britain and that of Western Europe, it may be necessary to do much more language teaching in schools than has been the practice hitherto [in Britain] This in turn may lead to a lengthening of the secondary school course as happened on the Continent where it is unusual for the secondary school course for the grammar school stream to finish before 19 or 20 years of age". Neither the schools nor the Ministry of Education have taken kindly to this particular view The place for teaching the less common languages may be in further education

Dr M B Brodie of the Administrative Staff College, Henley, and Dr. Walter Goldberg of the Gothenburg School of Business Administration, Sweden, were both concerned with management development Brodie stated that businesses which expand and grow more complex in character require relatively more managers While quantitative estimates must be cautious, since they are likely to transpose present-day notions and assumptions too readily to the future, one estimate which attempts to allow for qualitative changes suggests an increase of about 50 per cent in the number of executives needed over the next ten years

Throughout Europe, the shortage of staff of calibre for teaching and for research in managment is widespread and serious Weakness on the staff side cannot but jeopardize the whole quality and character of any programme "The limitations of educational ventures run with second-rate staff are too manifold to need enumerating "

Dr Goldberg gave details of important Swedish developments in the field of management education. In 1957, for example, an investigation showed that the relative number of academically trained top-level managers since 1944 had increased from 58 5 to 84 5 per cent in industry, and from 43 to 54 5 per cent in other enterprises Sweden proposes to increase its intake of students in business schools to 700 in 1970—more than double the 1955 figures of 325

All the papers have been brought together in a publication, *Continental Comparisons*, which can be obtained from the British Association for Commercial and Industrial Education, Publications Department, 26*a* Buckingham Palace Road, London. S W 1, price 10*s*

PERUVIAN ORCHIDS

THE appearance of Part 4 of Charles Schweinfurth's *Orchids of Peru** marks the completion of a task which has necessitated continuous and concentrated research over a period of many years At last we now have a comprehensive modern account of the orchids of an Andine country, a region which is not only one of the richest in orchids in the world, but which is the original home of the parents of many of our finest cultivated orchid hybrids This excellent account will not only be of service to students or visitors wishing to identify Peruvian orchids but will also facilitate the study of orchids from the neighbouring Andine countries of Bolivia, Ecuador and Colombia which have many species in common with Peru

This final part contains among others the important genera *Odontoglossum*, *Miltonia* and *Oncidium* (including *Cyrtochilum*), the last-named being represented by more than 70 species Like the three preceding parts, Part 4 is well illustrated, containing thirty-three charming line drawings and one half-tone plate of representatives of all the more important genera, thus bringing the number of illustrations in the whole work to 194 Of special interest are the three pictures of the remarkable alpine genus *Telipogon* most members of which are found only above 2,000 m altitude

Closer examination of the text in all these parts shows, however, how much more collecting is necessary in Peru before a really satisfactory final account of its orchid flora can be prepared The author has in many cases not seen any specimens of the species dealt with, having had to be satisfied with descriptions or photographs of the original specimens scattered in various herbaria Here then is an evident field for future work, since it cannot be doubted that with really good field collections available many of the outstanding problems could be solved and a more complete account given even of those species which are comparatively well known V S SUMMERHAYES

AGE OF THE BASALT FLOW AT OLDUVAI, EAST AFRICA

By PROF G. H. R. von KOENIGSWALD
Geological Institute, State University of Utrecht
AND
PROF W GENTNER and H. J. LIPPOLT
Max-Planck-Institut fur Kernphysik, Heidelberg

THE site of Olduvai in Tanganyika, East Africa, is known all over the world because of its remains of early man, the sequence of human industries and rich associated fauna, and we are all greatly impressed by the research, performed under difficult conditions, by Dr and Mrs Leakey Four different beds have been distinguished Bed I is underlain by a massive flow of basalt, and it should be possible to obtain here an age determination by means of the potassium–argon method We are greatly indebted to Mr S E Ellis of the Mineralogical Department of the British Museum (Natural History), who kindly gave us a rock specimen for that purpose (B M 1947/211· collected by K P. Oakley) This sample is called here *O* I As many implements at Olduvai are executed in basalt, we used two pebble tools from Bed I (collected by v Koenigswald, 1951), in order to try to get information for Bed I , these are the samples *O* II and *O* III

Table 1 POTASSIUM–ARGON AGES OF BASALT SAMPLES FROM OLDUVAI
$\lambda_{\beta} = 4·74 \times 10^{-10}\ a^{-1}$, $\lambda_{k} = 0·58 \times 10^{-10}\ a^{-1}$

Sample	Weight (gm)	A^{r}_{40} (10^{-7} c c /gm)	A^{at}_{40} (per cent)	K (per cent)	Age with potassium–argon (10^{6} *a*)
O I	0·52	0·58	88·6	1·13	1·3 ± 0·1
	0·51	0·60	87·9		
	0·51	0·57	90·6		
O II	0·51	1·91	70·2	2·17	2·25 ± 0·16
	0·71	1·93	69·6		
	0·51	1·94	72·4		
O III	0·52	0·93	89·8	1·67	1·4 ± 0·1
	0·60	0·86	89·3		
	0·61	0·96	88·0		
	0·69	0·92	87·9		

If we try to establish the age of Bed I with the help of the fauna, we find that *Elephas planifrons* and *Stegodon*, typical for the Villafranchian of Africa, are missing. There are many archaic types still present such as *Dinotherium* and *Mastodon*, but the dominant species among the elephants is *Elephas recki*, representing the same evolutionary stage as *Elephas antiquus* in Europe Beds I and II have many species in common which do not occur higher up According to Hopwood in ref 1· "There is no faunistic evidence to suggest that the lower part of the Olduvai series is of Lower Pleistocene age". Leakey expressed the opinion that Olduvai "extends from the beginning of the Mindel to the very end of the Riss glaciation" (ref 1, p 160) After the discovery of *Zinjanthropus*, however, Leakey included Bed I in the Lower Pleistocene, the Villafranchian Considering the various views expressed without further discussion we expect that Bed I has an age of 0·4–0·8 m yr (ref 2) and 0·1–0·8 m yr (ref 3) respectively

The basalt bed, however, has a considerably higher age determined by using potassium–argon. The analysis has been carried out on stony material reduced to small pieces. The average diameter of the fragments of the rocks was about 0·8 mm , which guarantees sufficient homogeneity

The basalt below Bed I has an age (determined using potassium–argon) of about 1·3 m yr The pebble tools from Bed I are not younger but older, and therefore not suitable for our purpose The age of *O* III, however, is only a little higher than that for *O* I and might be regarded as confirming the figures for *O* I

We see that the age determined with potassium–argon is about 0·5 m yr higher than we had expected them to be There are three possibilities for this (*a*) The age determined with potassium–argon is too high, because the amount of argon-40 (rad) is accumulated by inherited argon This cause can only be excluded by further work on distant samples (*b*) The sedimentation at Olduvai did not start directly after the formation of the basalt flow but considerably later (*c*) Bed I has an age of about 1·0 m yr and the former estimates were not correct

It is not easy to say which of the three alternatives may give us the right solution Adopting the last suggestion we would be forced to revise considerably our ideas about the duration of the Pleistocene, which might be necessary, but should only be done if more age determinations of Pliocene and Villafranchian rocks are available Therefore, it seems likely to us for the time being that a time-interval does exist between the basalt and the formation of Bed I

Just after Gentner and Lippolt had finished their report on these measurements, an article was published by Leakey *et al* [4] on the age of Bed I at Olduvai Their figures, based on biotite, oligoclase and anorthoclase crystals from various tuffaceous intercalation are higher (1·6–1·9 m yr) than ours, though their samples are geologically younger We thus wonder where this discrepancy comes from

We can exclude that this is conditioned by the technique of measuring, since we are in good agreement with the age determination of a late Trinil basalt from Java measured by Evernden *et al.* Both laboratories obtained an age of 0·5 m yr for this sample, which may be used to date the *Pithecanthropus erectus*

Thus the difficulty comes from the sample itself In connexion with another problem, we investigated different Pleistocene samples (biotite and sanidine) originating from tuffs and found that their ages, determined with potassium–argon, do not necessarily have to agree with the geological sequence, but may be too high because of inherited argon There is every appearance that this error may be present just in tuff minerals of low ages

Furthermore, we have some sedimentological and palæontological questions concerning an extended time-scale

For the top of Bed I the average age is given as 1·23 m yr , for the lower part as 1·75 m yr Consequently, the total of Bed I should have been formed during a period of (at least) 0·50 m.yr. One might expect that such a long period should be subdivided by fauna, sedimentation, dry and wet periods, industry; nothing of that kind has been observed Bed I is about 30 m thick, which would mean an average rate of sedimentation as low as 0 06 mm per year Where are the sediments to support this ? By such a slow rate of sedimentation every bone would completely disintegrate before it would have a chance to survive as a fossil, but Bed I contains a rich fauna. Certain places might have been temporarily dry, to allow occupation sites, but no soil horizons have been formed or marked disconformities Does not the preservation of the bones and the general unity of fauna and industry through the whole of Bed I give the impression of a 'normal' sedimentation ?

Perhaps there is a marked time-interval between Bed I and Bed II If we look at this new time scale, the top of Bed I is estimated to be 1 23 m yr old According to the same authors a post-Chellean II tuff in Bed II has yielded a date of 0 36 m yr If we estimate the bottom of Bed II to be 0 50 m yr. old, the supported interval would last nearly 0 75 m yr Here again we might ask why the faunæ of Beds I and II are roughly the same, having in common even archaic types of elephants, and why both beds, possessing the same grey colour, seem to rest conformably on each other Where are the soils or zones of weathering which would certainly have been formed during this considerable interval of time and should separate the beds ?

As the lower part of Bed I is said to have an age of 1 75 m yr the whole Pleistocene Period would have lasted well over 2 00 m yr This is more than double of what we, cautiously and with good reasons, have estimated

Having considered the many unanswered sedimentological and palæontological questions which make Olduvai a difficult test case, we prefer, as stated here to be cautious until more dates for the lower Pleistocene are available

THROMBOCYTOSIS EVOKED BY EXERCISE

By H. S. S. SARAJAS
Institute of Physiology, University of Helsinki

AND

A. KONTTINEN and M. H. FRICK
Wihuri Research Institute, Helsinki

THE mechanism(s) responsible for the rapid, over-all increase in hæmostatic activity in association with physical, emotional and other stress situations[1–4] has not been ascertained[4] Admittedly, the plasma fibrinogen content has been said to be elevated in such circumstances[4], but judging from Selye's survey[2] this response generally takes several days to reach maximum This is in accordance with later work by Rizza[5], who found that acute exercise in human subjects does not raise the plasma-levels of fibrinogen, prothrombin, Christmas factor or Factor V However, in the two normal subjects examined, Rizza observed some increase in the activity of the antihæmophilic globulin and was inclined to believe that the hypercoagulability associated with exercise might possibly be traced to this change Similar increase in the activity of the antihæmophilic globulin has been found after adrenaline infusions[6] On the other hand, it has been mentioned that the platelet count is also increased in stressful situations[4], but according to the evidence given by Selye[2] this response is not wholly consistent While moderate, short-term exercise has been found to raise the platelet count[7,8], it appears that following prolonged[9 10] as well as brief, strenuous exercise[11] no appreciable changes occur in the platelet count Gerheim and Miller[11] expressed the opinion that "the greatly increased circulation velocity during exercise may destroy enough platelets to mask a moderate increase in numbers"

It seems possible, then, that the hypercoagulability associated with exercise and related conditions is ascribable to thrombocytosis rather than to any increase in the levels of the coagulation factors in the plasma At all events, however, the question remains what is the ultimate mechanism of the thrombocytosis that seems to prevail in stressful situations It has been conjectured that the leucocytosis known to accompany exercise and related conditions is effected mainly by the concomitant increase in circulation[12–14] Conversely, the reversible hypothermic leucopænia (associated with thrombocytopænia and bleeding tendencies) has been traced to the reversibly retarded circulation inherent in hypothermia[15] To our knowledge, nevertheless, no attempts have been made to substantiate or quantitate the possible role of the hæmodynamic changes in the establishment of these corpuscular blood changes. Hence, we have examined the relevant hæmatological changes in human subjects undergoing graded muscular exercise as well as the relation of the changes to those in cardiac output and allied parameters

The counts of erythrocytes, leucocytes and thrombocytes (Fonio's method, counted per 2,000 red cells), including the hæmatocrit readings, were determined from the capillary blood and, in a part of the tests, also from the venous blood For work-loading, a bicycle ergometer and marching were employed. The cardiac output was determined by using the dye-dilution technique, and from the dilution curves mean circulation time was reckoned From the circulation time, again, 'relative circulation velocity' was derived (inverse value of the circulation time)

The results obtained, with special reference to the platelet and circulatory changes, may be outlined as follows

In the eight subjects studied, light muscular exercise lasting for some 10 min and capable of raising the cardiac output by 50–200 per cent resulted in an appreciable and consistent rise of the platelet count in the capillary blood. The figures obtained before and immediately after the exercise were 123,000–243,000 per mm ^{3} and 168,000–270,000 per mm ^{3}, respectively The percentage increments were 9-37, and the greatest numerical increment recorded amounted to 58,000 per mm ^{3} The platelet count in the venous blood showed a comparable increment, even if the figures were somewhat higher throughout The 'relative circulation velocity', derived from the mean circulation time, was in all cases increased in direct proportion to the increments in the cardiac output. Of special interest is the observation that the increments in the platelet count and in these two circulatory parameters were fairly commensurate.

More strenuous exercise of about 18 min. duration (testing the physical working capacity by Sjöstrand's method) in the same subjects yielded a more pronounced increase of the platelet count in the capillary blood, the resting values were 138,000–291,000 per mm.^{3}, whereas after the work-load was imposed the figures were 210,000–348,000 per mm.^{3} The highest numerical increment was 107,000 per mm.^{3}, and the percentage increments varied from 17 to 60. The recovery studies performed in this group of tests revealed that after 15 min. rest the platelet count had actually returned to the pre-exercise level (113,000–261,000 per mm.^{3}).

Ten miles marching within some 90 min. resulted in considerably different changes. In the ten subjects studied there were no marked alterations in the platelet count in the capillary blood, in eight individuals the platelet count showed increments of 2–22 per cent, whereas in two instances the count tended to decrease (4 and 8 per cent). After a 90-min. recovery period the platelet count remained substantially unaltered in most instances. Yet, in three cases it was found to be increased no matter what the response to the work-load was.

In this connexion it may be mentioned that the changes in the leucocyte count after these different work-loads and recovery periods were the same in direction as, but usually relatively greater than, those in the platelet count. There was a good correlation between the increments in the leucocyte count and those in the changes in circulation examined. The hæmatocrit values usually rose but only slightly, the greatest increase encountered was 5.5 vol. per cent. The small degree of hæmoconcentration indicates that the increased counts of platelets and leucocytes cannot be accounted for by the concurrent hæmoconcentration.

These preliminary results suggested the tentative conclusion that the leucocytosis and even thrombocytosis that accompany at least light and moderate short-term exercise are actually effected by the concomitantly accelerated circulation. The source of the leucocytes and platelets which appear to be released into the circulation may be the pulmonary vascular bed, particularly its venous side, which is known to remove and discharge leucocytes[13,16] and platelets[13] on changing circulatory conditions. But also, similar release may occur in the peripheral vascular compartments in general, as suggested by the biomicroscopic observations on the microcirculation in hypothermic subjects (cf. Sarajas[15]). Moreover, since the work of Eberth and Schimmelbusch, it is known that on acceleration of circulation leucocytes and platelets enter into the axial flow in increasing numbers (cf. Koller[17]). Especially during prolonged and brief, strenuous exercise other factors, such as an altered fragility and adhesiveness of these cellular blood elements, may come into play, and this would explain the slight and inconsistent leucocyte and platelet changes encountered in our marching tests.

The clear-cut and consistent rise in the platelet count, as observed in the present tests with light and moderate exercise of short duration, makes it evident that the hypercoagulability in association with exercise[1-3] is possibly related to a thrombocytosis and that this thrombocytosis is occasioned by the concomitant circulatory activation. The same mechanisms may be responsible also for the hypercoagulability said to accompany other stressful situations[2-4].

Finally, the question arises whether the thrombocytosis and hypercoagulability of this origin operates particularly in the establishment of coronary thrombosis, which is known to be precipitated by states of emotional and physical stress.

MODIFIED CUVETTES FOR PHOTOELECTRIC SPECTROPHOTOMETRY

By Dr. MALCOLM H. SMITH*

John Harrison Laboratory of Chemistry, University of Pennsylvania, Philadelphia

WITH the development of photoelectric spectroscopy to the point where even colorimetric techniques come closer and closer to being true spectrophotometry, the conventional vessel in which most solution measurements are made, and to which most optical coefficients are referred, has become the optical cuvette with 10 mm. light path. It is the purpose of this article to report a new approach to the problem of making spectral observations over an extended wave-length range, with convenience and accuracy, using modified cuvettes of this type. The discussion is centred around the use of hæmoprotein solutions, for the analyses of which this technique was evolved. It is stressed, however, that the principle is of the widest application and may be used over the whole of the spectrum wherever solutions are to be examined, whenever the solution would normally have to be diluted at some stage of the spectral examination.

It is often possible to arrange to dilute a solution so that it gives a conveniently measurable optical density over the whole of the wave-length range to be studied. There are occasions when this is not feasible, however. For example, many hæmoproteins (other than cytochromes) have relative extinctions at the ultra-violet, near ultra-violet, visible, and near infra-

---

* Present address: Molteno Institute, Downing Street, Cambridge, England.

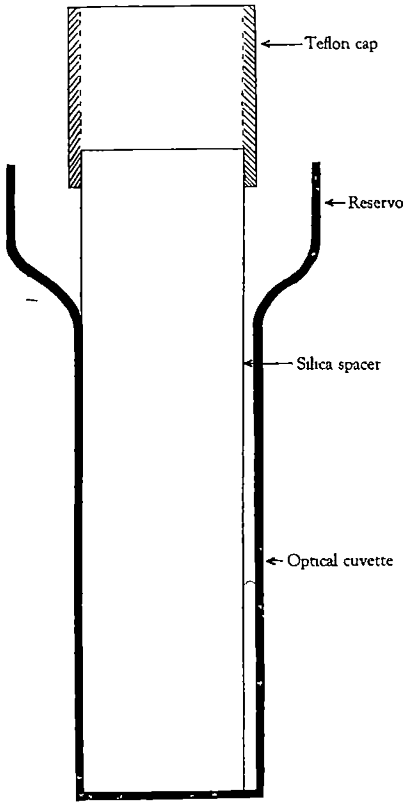

Fig 1 General purpose cell Optical path in plane of paper

red maxima of roughly 30, 100, 10 and 1, a range which is too great for the spectrophotometer to cover with accuracy, and certainly not with suitable clarity in the overall spectrum The desired result can only be obtained by starting with a solution which is of sufficient strength to resolve adequately the lowest peaks of the spectrum, and then reducing the optical density in order to resolve peaks which would otherwise be too intense This may be done in only one of two ways by diluting the solution (assuming that it still obeys Beer's law), or by reducing the optical path of the original solution.

Dilution, as a routine answer, may be criticized on numerous grounds Beer's law may not be obeyed by the solution; the process of dilution is time-consuming and inconvenient, mere dilution may upset equilibria in the experimental solution so that a special dilution medium may have to be prepared, dilution may in itself be undesirable where only small volumes of material are available to start with There remains the possibility of a mechanical reduction of the optical path of the starting solution Three methods are available

(1) *The use of an adjustable cell* These are expensive, need relatively large volumes of solution as compared with the standard cuvette, and must be provided with a reservoir to take the overflow when the path-length is reduced In addition, they are difficult to rinse adequately, and once rinsed they are difficult to dry adequately

(2) *The use of a second cell with a shorter path-length, for example, a 1-mm cell* This is certainly much more satisfactory than (1) There are still disadvantages, however In the first place, with cells as narrow as 1 mm, capillary effects make emptying and filling the cell rather a problem This means using a hypodermic syringe to get the solution in and out of the cell This is reasonably satisfactory, but the very fact that a second cell is employed more than doubles the actual manual operations involved

(3) *The use of a block of suitable material, for example, silica, inserted into the cell* In this case, the cell has to be partly emptied before inserting the spacer or else there is an overflow Furthermore, the amount of fluid to remain is rather critical, both to avoid overflow and to provide sufficient depth of fluid to cover the light beam

It might seem that, as between (2) and (3), (2) is the more satisfactory Nevertheless, it was felt that in principle (3) was the right approach, and steps were therefore taken to remove the disadvantages mentioned above The devices which evolved enable rapid and convenient scanning of extended wavelength ranges without the necessity of diluting the solutions, or even of removing them from the cuvette The descriptions are of actual models which have been in use for more than a year Possible modifications suggested by this experience are noted where appropriate

(a) General Purpose Cell

This is the standard cuvette modified to permit the rapid insertion of a spacer without overflow, and is made by fusing a reservoir on to the end of the cuvette, as shown in Fig 1. The exact dimensions of the reservoir may vary with the design of the spectrophotometer, and any optically suitable material may be employed for the cell as a whole, namely, 'Pyrex', silica, 'Perspex', etc The prototype, intended for use with the Beckman *DK*-1 recording spectro-

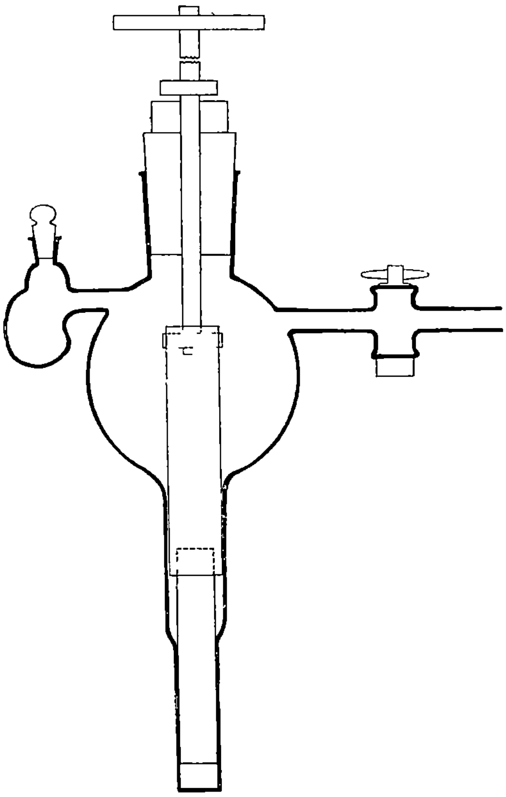

Fig 2 Gas-tight cell Optical path at right angles to plane of paper

photometer, was of 'Pyrex' glass and had a reservoir which was squared-off parallel to the sides of the cuvette The reservoir would take up about 2 ml of fluid A later model of silica has a reservoir of greater cross-sectional area which will take up a full 4 ml For these cells a silica spacer of the conventional type, that is, a block of silica 9 × 9 × 45 mm, was adapted by adding a cap of 'Teflon' to provide a handle for withdrawing the spacer-though, again, any optically suitable material may be utilized This was done by making a tight push-fit with the spacer into a piece of 'Teflon' tubing of the appropriate internal diameter (It may be noted in passing that the complete unit is very similar in principle and in form to the cups used in colorimeters of the Klett type)

(b) A Gas-tight Cell

The idea of attaching an optical cuvette to a gas reservoir, or tonometer, for observing reactions with gas mixtures goes back at least to Conant's work[1] in the late 1920's Since then, the use of a Thunberg tube with a sealed-on cuvette has become standard, since this enables further reagents to be added during the course of the experiment if necessary. The most sophisticated designs of this type appear to be those of Keilin and Wang[2] and of Rossi-Fanelli and Antonini[3], which incorporate a mobile spacer The spacer, however, is not readily controllable from the outside, particularly once the unit is *in situ* in the spectrophotometer The device described here incorporates a spacer which may be raised or lowered at will from the outside It consists (Fig 2) of a standard 'Pyrex' cuvette to which is sealed a glass bulb of about 70 ml internal volume A side-arm bulb of about 2 ml volume is provided for adding further reagents, and a two-way 'Teflon' tap controls filling and evacuation of the whole unit A standard spacer of the type mentioned above was pushed into a length of 'Teflon' tubing suspended from a cross-piece at the bottom of a stainless steel shaft. The 'Teflon' was free to swing on the cross-piece and this provided the slight amount of play necessary to ensure that the spacer never became jammed in the cuvette through error in the alignment of the spacer assembly The stainless steel shaft passed through an 'Asco' gland (A F Smith Co, Rochester, N Y) fitting into a standard ground glass joint at the top of the reservoir The 'Asco' gland is a 'Teflon' stopper which forms a gas-tight seal, outside and inside, by means of rubber O-rings The inner O-ring may be tightened against the shaft by means of an adjusting device The pressure on this O-ring was so arranged that the shaft could be raised or lowered easily, and yet would not move from the set position even with an internal vacuum

If only the vacuum from a water pump is employed, the 'Teflon' stopcock and the rubber O-rings will maintain the desired gas pressure for a considerable time Hence, one can avoid the use of sealing grease, thereby eliminating possible contamination of the solution, and making for quicker and easier cleaning In principle, one should be able to use the cell at much lower pressures, at least down to 0 1 mm. of mercury, but it does not seem possible to quote a lower limit at present owing to individual variations among 'Teflon' stopcocks

With the complete cell one can, for example, determine the spectrum of oxyhæmoglobin from 350 to 700 mμ in one operation, followed immediately by the spectrum of deoxygenated hæmoglobin over the same range, produced by adding a little sodium dithionite from the side-arm Both spectra can be

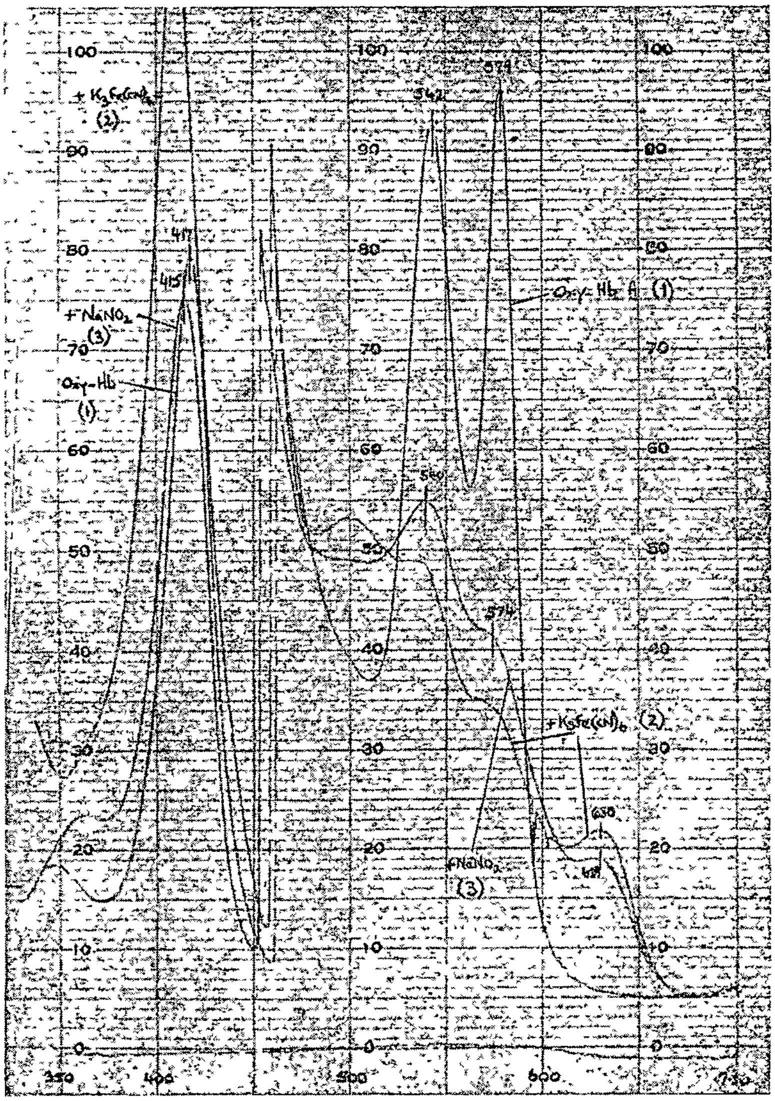

Fig 3 Traces obtained using the general purpose cell in conjunction with a recording spectrophotometer Spacer inserted at about 460 mμ in each case Ordinates optical density Abscissæ wave-length in mμ (1) Human oxyhæmoglobin, (2) acid methæmoglobin from (1) + solid potassium ferricyanide, (3) nitrite methæmoglobin from (2) + solid sodium nitrite

taken under nitrogen, so reducing the liability of oxidation, and this can be replaced by carbon monoxide to give the carbon monoxide–hæmoglobin spectrum without disturbing the solution. The same sequence of operations would be considerably longer and more cumbersome to carry out by the usual procedures, and there would be much greater risk of artefacts due to the presence of oxygen and the mechanical agitation involved.

Practical Points

With both types of cuvette, the use of standard spacers, rather than spacers designed specifically for the purpose, meant that the rise and fall of the spacer had to be carefully checked to ensure that it would enter and leave the light beam completely. This was done by moving the spacer slowly into the light beam and observing the resultant optical density changes. The limits of the beam can be very accurately noted in this way, and were recorded for further work by marking the cuvettes themselves. Also as a result of using standard spacers, in both cells the spacer would no longer go to the bottom of the cuvette and a minimum volume of 2·5 ml. of solution was required. Ideally, one would use longer than normal spacers, which would obviate the need for an added 'handle', and would make possible the use of the cells with very small volumes, that is, a minimum of about 1 ml. of fluid if the cells were raised relative to the light beam.

Fig. 3 shows an actual unretouched trace which demonstrates the capabilities of this technique when used in conjunction with a recording spectrophotometer. Three successive spectra were recorded: oxyhæmoglobin, methæmoglobin formed by the addition of a little solid potassium ferricyanide, and nitrite methæmoglobin formed by the further addition of a little solid sodium nitrite. The traces were recorded using the standard cuvette in a Beckman *DK*-1 recording spectrophotometer. At the point where the optical density was rising sharply in the region of 460 mμ the cell compartment cover was quickly removed and the spacer inserted, the cover then being replaced. The very smooth transition, and the ease with which the complete spectrum may be visualized, should be especially noted. Similar results were obtained with the gas-tight cell, save that it was unnecessary to move the cell compartment cover. The exact procedure to be adopted when inserting the spacer will depend on the instrument being used, and its position in relation to outside light sources. With the *DK*-1, as used in this work, it was possible to have the compartment cover partly open the whole time without being able to detect stray light in the machine. In less-favourable situations, the cell could easily be handled through a black cloth, or placed under a light-tight box standing over the cell compartment.

Both cells have been in fairly continual use for about a year without showing any signs of scratching to either cuvettes or spacers. Neither has there been the slightest difficulty with bubbles adhering to the optical faces. In the original gas-tight cell, the 'Asco' gland used was a size 24/40 with 6-mm. bore and standard taper, the smallest then available. A 10/30 gland with standard taper and 6-mm. bore is now available, and this is a most convenient size. Apart from this, two immediate modifications, in principle rather than design, have been suggested in use. The primary one is that the useful range of the cells would be enormously extended in both the ultra-violet and infra-red regions if silica cuvettes were employed (in conjunction with silica spacers). There is no serious difficulty in doing this, and a standard general purpose cell has already been constructed in this material. Secondly, the usefulness of the cells could be further extended by the provision of spacers with 9 mm. optical path in one direction, and 8 mm. optical path at right angles. In the case of the hæmoproteins mentioned here, the 8-mm. spacing would enable one to examine the protein band around 280 mμ at a more suitable optical density in a continuous scan from 700 mμ down to 220 mμ.

The devices described here were developed and constructed during tenure of National Science Foundation grant *G* 7657 and U.S. Public Health Service grant *A* 3187 (*C*3), and it is a particular pleasure to acknowledge the interest and encouragement of Prof. Philip George.

EVIDENCE FOR THE PHOTO-ASSOCIATION OF AROMATIC HYDROCARBONS IN FLUID MEDIA*

By Dr. B. STEVENS

Department of Chemistry, University of Sheffield

THE pattern of singlet and triplet π-electron energy stages of an aromatic molecule A ($^1\Sigma$) shown in Fig. 1*b* closely follows that for an atom with ground state ^1S. A logical development of this pattern should lead us to expect the existence of an electronically excited dimeric state $A_2{}^*$ in fluid media (Fig. 1*b*), corresponding to the stable excited diatomic molecule formed collisionally from excited and unexcited atoms of an inert gas[1], for example

$$He^* + He \rightarrow He_2{}^* \rightarrow He + He + h\nu \text{ (continuum)}$$

(the asterisk denotes electronic excitation). Moreover, the radiative relaxation of the photo-associated species $A_2{}^*$ to a dissociated ground state (process 4 of Fig. 1), like that of its diatomic counterpart, should be accompanied by a structureless emission at longer wave-lengths than the corresponding molecular fluorescence, whereas the reverse process of absorption will be limited by the extent to which association occurs in the ground state.

Such an emission was first reported by Förster and Kasper[2] as a broad, blue, structureless band, which replaces the violet, structured fluorescence of dissolved pyrene as its concentration is increased. No cryo-

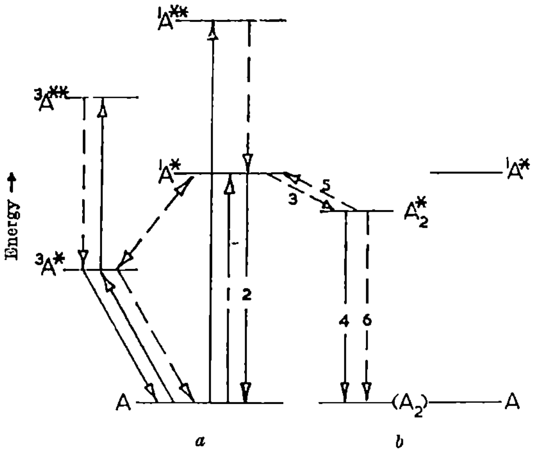

Fig 1 Electronic energy-levels of aromatic hydrocarbon A in monomeric (a) and dimeric (b) forms Radiative and non-radiative transitions are indicated by solid and dashed lines, respectively

scopic evidence was obtained for the association of unexcited molecules even in the most concentrated solutions and the molecular absorption spectrum remains unchanged over the range of concentrations investigated Since the absorbing species is monomeric the operative processes may be represented by the scheme

$$\begin{array}{l} A + h\nu \xrightarrow{1} A^* + A \xrightarrow{3} A_2^* \xrightarrow{4} (A_2) + h\nu\ \text{(blue)} \\ \qquad\qquad \downarrow 2 \qquad\qquad\qquad\qquad\qquad \text{(structureless)} \\ \qquad\qquad A + h\nu\ \text{(violet)} \\ \qquad\qquad \text{(structured)} \end{array}$$

where the asterisk denotes an electronically excited state and the processes are numbered according to Fig 1 The rate constant[3] for process 4 is ~ 10^6 sec $^{-1}$ although a small component of the blue emission with a lifetime of ~ 10^{-3} sec has been observed in degassed solutions[4] 3,4-Benzpyrene[5] and a few other pyrene derivatives[2] show a similar effect to a smaller extent

If the absence of dimer emission in other aromatic systems is due to the relatively high probability of competing processes, the evidence for photo-association must be based on these processes which include

(a) dissociation (process 5) proposed[6] to account for delayed fluorescence observed in the vapours of a number of aromatic compounds recorded in Table 1

$$A_2^* \rightarrow A^* + A \qquad (5)$$

In each case the spectrum of delayed fluorescence is identical with that of the molecular fluorescence originating from the lowest excited molecular singlet state A *, but the lifetime is about 10^{-3} sec , the ratio of delayed to total fluorescence intensities increases with the pressure of the vapour, and the small temperature dependence of the delayed component lifetime is incompatible with a mechanism in which the fluorescent state is thermally re-populated from the lowest triplet level The absence of dimer emission under these conditions indicates that its radiative lifetime is at least 10^{-3} sec and is probably at least ten times longer A similar effect reported by Kautsky[9] in 1935 for very dilute solutions of a number of dyes, hæmatoporphyrin and chlorophyll, was interpreted in the same way

Since process 5 requires an activation energy, it is less predominant at room temperatures than.

(b) internal conversion (process 6) which leads to

$$A_2^* \rightarrow (A_2) \rightarrow A + A \qquad (6)$$

the overall self-quenching of fluorescence in solution[10] exhibited by several of the aromatic hydrocarbons listed in Table 1 In the vapour phase process 5 is dominant in the majority of cases investigated under the conditions of observation, however, a quantitative treatment[13] of the simultaneous self-quenching and delayed fluorescence observed in anthracene vapour has shown that processes 5 and 6 are mutually competitive, which suggests that photo-association is an essential step in the self-quenching mechanism A value of 7 6 kcal /mole obtained[13] for $E_5 - E_6$, the difference in activation energies of processes 5 and 6, provides a lower limit to the heat of photo-association in this case, and since the rate constant for process 6 is ~ 10^3 sec $^{-1}$ at 220° C (ref 13), the excited dimeric state of anthracene should have a lifetime of at least 10^{-3} sec with respect to internal conversion in solution at room temperature The remarkable duration of this electronically excited species should promote

(c) efficient energy transfer to an acceptor B (process 7)

$$A_2^* + B \rightarrow (A_2) + B^* \qquad (7)$$

which has been proposed[14] to account for the identity of the anthracene vapour fluorescence spectrum and the delayed fluorescence spectrum of phenanthrene vapour containing not more than 10^{-4} mm (about 10^{-8} mole/l) of anthracene If the lifetime of phenanthrene in its photo-associated state is $\geqslant 10^{-3}$ sec , this concentration of anthracene acceptor is sufficient to account for the effect observed, which provides an upper limit of 5 4 kcal /mole for the heat of formation of the phenanthrene dimer Furthermore, the efficiency of process 7 in this case is consistent with the conservation of overall spin angular momentum which is only possible if the photo-associated donor is in a singlet state The pyrene-sensitized delayed fluorescence of naphthacene vapour present in trace quantities requires a similar interpretation[8] since delayed fluorescence has not been observed from naphthacene vapour alone where self-quenching is extremely efficient[11] In this case the difference in energies of pyrene and naphthacene molecules in their lowest excited singlet states provides an upper limit of 15 2 kcal /mole for the heat of photo-association of pyrene

If these competing processes are acceptable criteria for the formation of an excited dimeric species by the collisional process 3, the failure of 9,10-diphenylanthracene to exhibit either delayed fluorescence in the vapour phase[8] or self-quenching in solution[15] suggests that the photo-association of this non-planar molecule is sterically hindered However, the observations listed in Table 1 indicate that the photo-association of planar aromatic molecules is of general occurrence, and, despite the absence of direct evidence in the majority of cases, it must be concluded that in fluid media the stable form of planar aromatic molecules in their excited singlet states is dimeric The term 'excimer' has been proposed[4] to distinguish this state from the excited dimer of certain dyes which is produced by absorption from a stable dimeric ground state[16] and which has the quite different properties[4] shown in Table 2 Excimer formation, like triplet state population, is not necessarily limited to aromatic systems

Table 2 PROPERTIES OF EXCIMER AND EXCITED DIMER

	Excimer	Excited dimer
Ground state	dissociated	stable at room temperature
Dimerization	follows act of light absorption	precedes act of light absorption
Radiative relaxation	forbidden	allowed*
Corresponding absorption	not observed	increases with concentration

* According to intensity of corresponding absorption (ref 16)

Although photo-association appears to be of general occurrence unless sterically hindered, the intermolecular binding forces will depend on the electronic properties of the molecules involved and may be of less general origin A resonance splitting of the two-fold degenerate electronic levels of identical molecules in a parallel sandwich configuration has been treated by Hoijtink[17], who concludes that the stable state is a singlet with an energy some tenths of an electron-volt below that of the corresponding state of the monomer, and that owing to its centre of symmetry the radiative relaxation to a dissociated ground state is orbitally forbidden, these conclusions are in qualitative agreement with the experimental observations although the symmetry restriction requires a strictly parallel configuration of the aromatic planes which is unlikely to persist for 1 msec in the vapour phase or even in solution at room temperature

An explanation of excimer emission in solution with $k_4 \sim 10^8$ sec $^{-1}$ and delayed fluorescence in the vapour where $k_5 \sim 10^3$ sec $^{-1}$ appears to require at least two states of the pyrene excimer between which interaction is weak or dependent on temperature Murrell has shown (in a private communication) that the charge-transfer state A^+A^- of pyrene, corresponding to an interplanar distance of $\leqslant 3\ 5$ Å, lies below the first excited singlet state of the monomer, in which case configuration interaction with the resonance state may be responsible for the exceptional radiative properties of this excimer in solution A third possibility is the doubly excited state suggested by Hoijtink (private communication) to explain the remarkable resistance to radiative relaxation exhibited by excimers in the vapour state, Colpa[18] has pointed out that a doubly excited dimeric singlet state correlates with two molecular triplet states, and since the lowest excited singlet energy of molecules such as anthracene and naphthacene is almost exactly twice that of the corresponding triplet-level, the doubly excited state could be populated by a diabatic process following the collision of molecules in the ground and excited singlet states.

STRUCTURE AND PROPERTIES OF THE FLAVOHÆMOPROTEIN, CYTOCHROME b_2 (L(+)-LACTATE DEHYDROGENASE OF BAKER'S YEAST) AND OF HÆMOPROTEIN, FLAVOPROTEIN AND APOPROTEIN DERIVATIVES

By PROF R K. MORTON

Department of Agricultural Chemistry, Waite Agricultural Research Institute,
University of Adelaide

CYTOCHROME b_2 was first observed in 1942 by Bach, Dixon and Keilin[1], and was partly purified by Bach, Dixon and Zerfas[2,3], who found that the cytochrome was closely associated with the lactate dehydrogenase of aerobic baker's yeast In 1954 Appleby and Morton[4,5] reported the purification and crystallization of cytochrome b_2 and showed that it was identical with yeast L(+)-lactate-cytochrome c reductase (L(+)-lactate dehydrogenase) The crystalline enzyme was found to be a flavo-

Table 1. Nomenclature of Derivatives of Cytochrome b_2*

Name	Non-protein groups	L(+)-Lactate-cytochrome *c* reductase activity	Principal absorption bands (mμ)	Other properties
Type I cytochrome b_2	DNA FMN† Protohæm	Active	α, 557, β, 528, γ, 423.5, u.v., 265	Crystalline, molecular weight, 172,000
Type II cytochrome b_2	FMN Protohæm	Active	α, 557, β, 528, γ, 423.5, u.v., 269.5	Crystalline
Type III hæmoprotein-550	DNA Ferro-porphyrin *c*	Inactive	α, 550, β, 521, γ, 415, u.v., 257	Crystalline, reduced by cytochrome *c* reductases, oxidized by cytochrome *c* oxidase
Type IV hæmoprotein-557	Protohæm	Inactive	α, 557, β, 528, γ, 423.5, u.v., 276	Poorly crystalline, slightly autoxidizable
Type V flavoprotein	DNA (?) FMN	Inactive	Oxidized, 445, 375, u.v., 266	
Type VI apoprotein	DNA	Inactive	u.v., 260 mμ	

* The full name for protein derivatives should include reference to the parent material—thus 'type III cytochrome b_2-hæmoprotein-550'.
† Riboflavin phosphate.

hæmoprotein since it contained equimolecular amounts of riboflavin phosphate and of protohæm as prosthetic groups[4,6,7]. In addition, the enzyme contained a constant proportion of a deoxyribonucleic acid (DNA)[8,9] of small molecular weight as estimated by end-group analysis[9].

The DNA-containing cytochrome b_2 is regarded as the naturally occurring form of the enzyme, and is now known as type I-cytochrome b_2 (ref. 10) (Table 1). The enzymic[4,5,11], chemical[4,7-9,11,12] and physico-chemical[4,8,11,13,14] properties of crystalline type I cytochrome b_2 have been described. The enzyme is homogeneous with respect to sedimentation as indicated by boundary analysis[15] of sedimentation patterns of the enzyme in lactate-pyrophosphate-ethylenediamine tetraacetate buffers, and by sedimentation patterns after treatment with 2.6 *M* and 5 *M* urea[13-15]. Only a single protein component has been detected by moving-boundary electrophoresis[4,8,14]. Although the possible existence of a flavoprotein and a separate hæmoprotein in crystalline type I cytochrome b_2 was recognized by Appleby and Morton[4], continued work since 1954 has produced no evidence for this hypothesis. Boeri *et al.*[16] used a non-crystalline preparation and confirmed the finding of Appleby and Morton[4] that cytochrome b_2 is a flavohæmoprotein identical with yeast L(+)-lactate-cytochrome *c* reductase.

Further information concerning the structure and properties of cytochrome b_2 has been obtained by modification of type I cytochrome b_2. A series of derivative proteins have been prepared, some in the crystalline state. Table 1 gives the nomenclature adopted for the various modified proteins so obtained. Both the hæmoprotein and flavoprotein derivatives are inactive as lactate-cytochrome *c* reductases, as is the apoprotein (the protein derivative free of both prosthetic groups). Lactate-cytochrome *c* reductase activity has been re-established by the re-combination of riboflavin phosphate with the hæmoprotein derivative and by the stepwise addition of protohæm and of riboflavin phosphate to the apoprotein, either alone is ineffective. The two prosthetic groups are attached at the active centre of the one protein, the presence of both groups is essential for enzymic reduction of cytochrome *c*. It is concluded that reduction of cytochrome *c* by the native enzyme involves intra-molecular electron transfer from the flavin to the hæm prosthetic group.

For these investigations, twice-crystallized type I cytochrome b_2 was the usual starting material. Unless otherwise specified, all solutions contained 0.1 m*M* ethylenediamine tetraacetate, and all work was carried out under anaerobic conditions at 0–2° C., with de-aerated solutions equilibrated with oxygen-free nitrogen. Solutions were usually prepared by dissolving crystals of type I cytochrome b_2 in 0.5 *M* sodium lactate–0.04 *M* sodium pyrophosphate–0.1 m*M* ethylenediamine tetraacetate, *p*H 6.8, the protein concentration was 15–25 mgm./ml. Enzymic activities were estimated at 25° C. and as described by Appleby and Morton[5], and by Morton and Shepley[10], rates being calculated from changes in optical density due to the enzyme during the first minute. Protein concentration was calculated from the optical density of the reduced form of the pigment[8] or by the method of Lowry *et al.*[17] Fluorescence was observed visually on irradiation with a 'Hanovia' lamp at about 360 mμ, or measured with an EEL fluorimeter.

Crystalline forms of type I cytochrome b_2. The ferrocytochrome is regularly obtained as crystals which appear as shallow bipyramids belonging to the tetragonal system[4,5]. Crystals have also been obtained by precipitation with acetone, according to the conditions, each of the crystalline forms shown in Fig. 1 may occur. The crystals shown in Fig. 1*B* appear to be macles (hemitropes), formed by co-crystallization of the protein and salt developing on a common crystal face. The ferricytochrome has also been obtained as tan-coloured bipyramids, in contrast to the pink-coloured crystals of the ferrocytochrome. The crystals of the oxidized enzyme give solutions which are burgundy red when concentrated and brown when dilute, the absorption spectrum of a concentrated solution shows a band rising from about 620 mμ to a maximum at 533 mμ, with a minimum at 510 mμ, and a distinctive shoulder at 563 mμ. The peak at 532–535 mμ and the shoulder at 563 mμ are seen as absorption bands in a micro-spectroscope.

The distinctive crystalline forms of type I cytochrome b_2 depend on the presence of the DNA, flavin and hæm group in the protein, dissociation of any one of these will either prevent crystallization under the conditions used or change the crystalline form obtained. By suitable treatments which destroy enzymic activity, but which leave the prosthetic groups intact on the protein, enzymically inactive crystals of cytochrome b_2 have been obtained.

Crystalline type II cytochrome b_2. The deoxyribonucleic acid of native cytochrome b_2 has a marked influence on the electrophoretic mobility, the sedimentation coefficient, and the dependence on concentration of the sedimentation coefficient of the enzyme[14,15]. However, removal of the deoxyribonucleic acid by salt-precipitation of the protein does not interfere with the dehydrogenase activities of the protein[8]. Crystallization of the resultant type II cytochrome b_2 as large bi-pyramidal prisms belonging to the hexagonal system has been described by Morton and Shepley[10]. Type II cytochrome b_2 has equimolecular

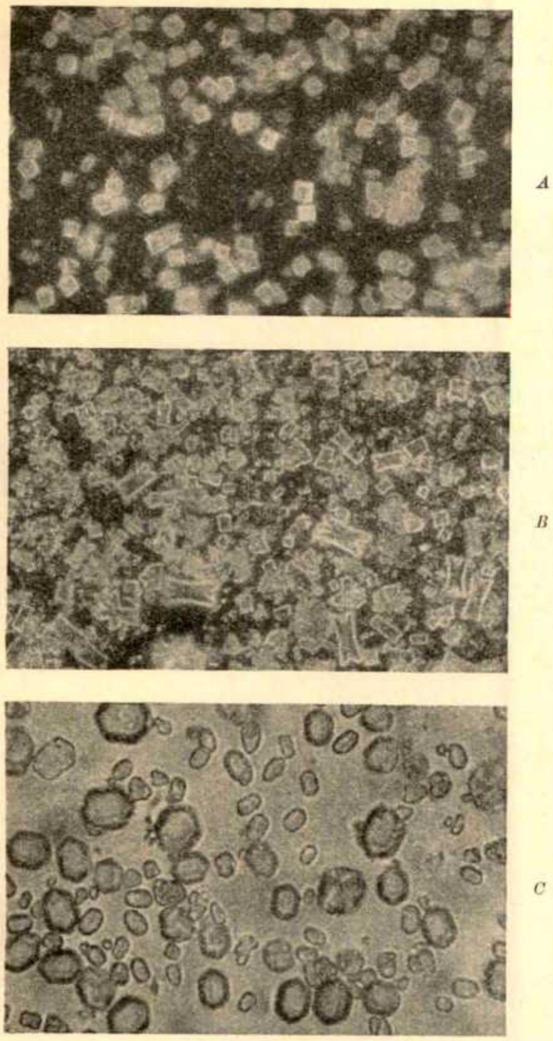

Fig. 1. Different crystalline forms of type I cytochrome b_2 obtained by acetone precipitation; the forms vary according to the conditions used for preparation. *A*, × 200; *B*, × 200; *C*, × 300

proportions of riboflavin phosphate and of protohæm and similar specific activities to type I cytochrome b_2 (refs. 10 and 11).

The occurrence of cytochrome b_2 as a crystalline protein, which may be obtained in a number of characteristic crystalline forms, each having equimolecular proportions of protohæm and of riboflavin phosphate, strongly supports the extensive physico-chemical evidence for the homogeneity of the protein; fortuitous association of a flavoprotein enzyme and of a separate hæmoprotein in cytochrome b_2 obtained by so many different purification and crystallization procedures becomes so improbable that this hypothesis may now be dismissed.

Cytochrome b$_2$ *- hæmoprotein - 550* (*type III hæmoprotein*). This is an enzymically inactive, flavin-free derivative of the enzyme. It was obtained from recrystallized type I cytochrome b_2 fortuitously, by acetone precipitation under conditions to be described elsewhere[18], as somewhat irregular crystalline plates.

The absorption spectrum of both the reduced and oxidized forms are remarkably similar to those of horse-heart and of yeast cytochrome *c*, but the spectra differ considerably in the ultra-violet region, largely due to the DNA-component of type III hæmoprotein. The extinction coefficients, expressed per mole of protein-bound hæm, are substantially the same for the α-, β- and γ-bands of the enzymically reduced cytochrome *c* and the type III hæmoprotein. The type III hæmoprotein derivative resembles cytochrome *c* in the following chemical properties: the pyridine hæmochromes are qualitatively identical for the α-, β- and γ-bands; the prosthetic group is not split by acid-acetone or acid-methylethylketone; treatment with silver sulphate in acetic acid causes distinctive changes in spectra, consistent with cleavage of thio-ether bonds, although the reaction products have not yet been identified. Like cytochrome *c* it is not autoxidizable at *p*H 7 and does not combine with carbon monoxide; it is reduced by ascorbic acid and by cytochrome b_2 (lactate-cytochrome *c* reductase); the reduced hæmoprotein is oxidized by cytochrome *c* oxidase from heart-muscle. However, whereas horse-heart cytochrome *c* has an isoelectric point of 10·2, type III hæmoprotein-550 has similar electrophoretic mobility to type I cytochrome b_2. It migrated very slowly in 12 hr. on electrophoresis at *p*H 6·8 in 0·3 M sodium lactate–0·05 M sodium pyrophosphate–0·1 mM ethylenediamine tetraacetate, *p*H 6·8, ionic strength 0·63, as a single component. The sedimentation coefficient was 3·4 Svedbergs (at 1·3 mgm. protein/ml.), and thus approximately half that of type I cytochrome b_2.

In view of the remarkable similarity to cytochrome *c*, including reduction by cytochrome *c*-linked dehydrogenases, and the available chemical evidence, it is tentatively concluded that cytochrome b_2-hæmoprotein-550 is a derivative of type I cytochrome b_2 containing at least one thio-ether bond from the protein to the hæm prosthetic group. It is likely that (*a*) reactive sulphydryl groups of cytochrome b_2 were exposed, possibly arising from cleavage of disulphide bonds in the original material; (*b*) these sulphydryl groups attacked the vinyl side-chains of the protohæm prosthetic group during acetone treatment of the protein, forming a thio-ether bond to the protein. This work will be described elsewhere[18], since it provides a possible model for physiological formation of cytochrome *c* from a protohæmoprotein precursor. The formation of type III hæmoprotein gives further support for the importance of highly reactive sulphydryl groups in cytochrome b_2[7,13,14]. Moreover, the similarity of the absorption spectra of cytochrome *c* and of type III hæmoprotein in the visible and near ultra-violet regions shows that similar amino-acid residues are co-ordinated with the iron atoms of the hæm residues in cytochrome *c* and in cytochrome b_2. Whereas cytochrome b_2 has two flavin and two hæm groups per molecule, and a molecular weight of 172,000 (refs. 14 and 19) hæmoprotein 550 appears to have one hæm group per molecule, and probably has a much lower molecular weight.

Cytochrome b$_2$ *- hæmoprotein - 557* (*type IV hæmoprotein*). This modification of type I cytochrome b_2 was obtained by removal of the flavin group of the enzyme by ammonium sulphate precipitation at *p*H 3·2. Loss of enzymic activity was proportional to the amount of riboflavin phosphate removed in the supernatant. The final product had about 0·02 times the amount of flavin in type I cytochrome b_2, and was correspondingly inactive with cytochrome *c*, ferricyanide, and dyes as acceptors for the dehydrogenase. The ferro-hæmoprotein has absorption maxima at 557, 528, 423·5 and 350 mμ; it does not combine significantly with carbon monoxide; and is only slightly autoxidizable, indicating a minimum of denaturation during the preparation. Rather poor crystals, which appeared as rectangular plates, were obtained by slow precipitation of this hæmoprotein with acetone. The sedimentation coefficient (1·3 mgm./ml.) was 7·94 Svedbergs; only a single protein component was detected on sedimentation. The prosthetic group is protohæm, as in cytochrome b_2. As shown here, enzymic activity of the enzymically inactive hæmoprotein is partly restored by recombination with riboflavin phosphate.

Cytochrome b_2-hæmoprotein-557 is probably closely related to a hæmoprotein which was crystallized by Okunuki and co-workers in 1957 [20]. The latter material, however, was highly autoxidizable; the effect of carbon monoxide was not reported. Although widely quoted as evidence for the existence of separate flavoprotein and hæmoprotein ('cytochrome b_2') moieties in L(+)-lactate-cytochrome *c* reductase of yeast, it is clear that the material obtained by Yamashita *et al.* was a derivative of native cytochrome b_2 obtained by denaturation of the enzyme during isolation[7,11].

Cytochrome b₂ *- flavoprotein (type V flavoprotein).* The lability of the flavin group of cytochrome b_2 creates considerable difficulty in selective removal of the hæm group without simultaneous depletion of riboflavin phosphate. However, it was found that the hæm group was quantitatively removed without extraction of the riboflavin phosphate by the following procedure. About 5 mgm. of freshly prepared crystals of type I cytochrome b_2 were dissolved in approx. 3 ml. of 0·1 *M* potassium cyanide at 0° C., and acetone pre-cooled to – 20° C. was slowly added to the solution at – 2° to – 5° C. until all the protein was precipitated. The yellow precipitate was washed with 60 per cent (v/v) acetone at – 15° C. and dissolved in about 2 ml. of 0·1 *M* sodium lactate, *p*H 7·5. Some insoluble protein was removed by centrifuging. The solution was dialysed against 0·1 *M* sodium lactate – 0·05 *M* sodium pyrophosphate – 0·1 m*M* ethylenediamine tetraacetate for 4 hr. Some insoluble protein was removed by centrifuging. Application of this procedure for removal of the prosthetic group of other hæmoproteins is being examined.

The flavoprotein derivative so obtained has 1 mole of riboflavin phosphate per 80,000 gm. as does native cytochrome b_2; however, the flavin group of the derivative, unlike that of native cytochrome b_2, is fully fluorescent. The absorption spectrum of the type V-flavoprotein shows maxima at 266, 375, and 445 mμ; there is a slight shoulder at 418 mμ, probably due to contaminant hæm material. These maxima correspond with those observed in the difference spectrum between native cytochrome b_2 and a preparation treated so that the hæm group was reduced but the flavin oxidized; a similar difference spectrum was found by Hasegawa and Ogura[21].

The type V flavoprotein wss enzymically inactive with lactate as substrate and with cytochrome *c*, ferricyanide, or 2 : 6-dichlorophenol indophenol as acceptors; enzymic activity was not restored by incubation at 0° C. with protohæmin. The material is readily denatured with simultaneous dissociation of the flavin group.

Cytochrome b₂ *- apoprotein (type VI - apoprotein).* Simultaneous removal of both the flavin and hæm prosthetic groups was accomplished by treatment of type I cytochrome b_2 crystals with acid-acetone at – 40 to – 60° C. The colourless apoprotein has a single absorption peak at about 260 mμ. Although there was considerable amount of denaturation, some of the protein was readily soluble in dilute lactate-pyrophosphate buffer. With this material, recombination of flavin and hæm groups partly re-established enzymic activity, but a fraction of the protein only soluble in more concentrated buffer was completely inactive.

Restoration of lactate dehydrogenase activity in hæmoprotein-557 and in apoprotein from cytochrome b₂. Table 2 shows that the inactive, type IV hæmoprotein-557 may be re-activated by incubating with riboflavin phosphate. The resultant protein catalyses reduction of cytochrome *c*, ferricyanide, 2 : 6-dichlorophenol indophenol and phenazine methosulphate. Whereas about 12 per cent of the ferricyanide reductase activity of type I cytochrome b_2 was recovered, addition of the flavin group restored only about 1 per cent of the cytochrome *c* reductase activity. Thus, as compared with reduction of ferricyanide, reduction of cytochrome *c* involves a more specific orientation of the two prosthetic groups.

Table 2. RESTORATION OF LACTATE DEHYDROGENASE ACTIVITY OF TYPE IV HÆMOPROTEIN-557

Acceptor	Hæmoprotein-557	Hæmoprotein-557 plus riboflavin phosphate
Cytochrome *c*	20	120
Ferricyanide	< 10	1,640
2 : 6-Dichlorophenol indophenol	7	90
2 : 6-Dichlorophenol indophenol plus phenazine methosulphate	10	140

The hæmoprotein solution was incubated with riboflavin phosphate (approx. 3 moles per 80,000 gm. of protein) at *p*H 7, and at 0° C., for about 2 hr. Activities were estimated as described by Morton and Shepley (ref. 10); they are given as μmoles of acceptor reduced per hr. per ml. of solution of hæmoprotein.

Further information concerning the functions of the two prosthetic groups was obtained from attempts to re-establish activity with a type VI apoprotein. The inactive material was incubated at *p*H 7·5 with either 1·5 moles of protohæmin per 80,000 gm. of protein or with 3 moles of riboflavin phosphate per 80,000 gm. of protein, or successively with each of these for 6–8 hr. at 0° C. At the end of this period (about 16 hr.), activities of the various materials, alone and in several combinations, were tested.

The apoprotein-hæmin and apoprotein-flavin incubates were inactive. Moreover, there was no reduction of any acceptor in the presence of lactate when portions of both the apoprotein-hæmin and the apoprotein-flavin preparations were added to the reaction mixtures. However, the preparation which had been incubated with hæmin for 6 hr. and afterwards with riboflavin phosphate showed a considerable activity with each acceptor. Fig. 2 shows the restoration of activity with cytochrome *c* as acceptor; similar results were obtained with ferricyanide and 2 : 6-dichlorophenol indophenol. Significantly, no activity was found in the preparation in which the addition of hæmin followed the addition of riboflavin phosphate. In a separate experiment, it was shown that some activity was recovered after incubation with both hæmin and riboflavin phosphate at the one time.

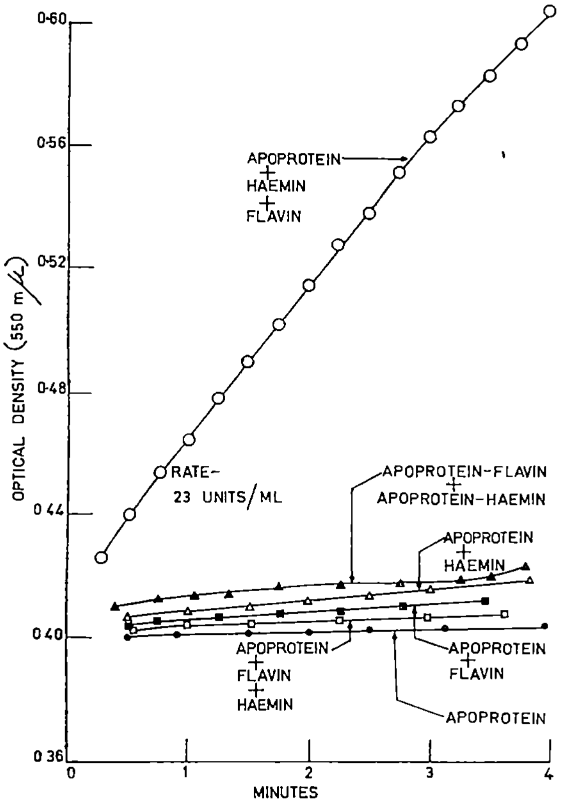

Fig 2 Restoration of lactate-cytochrome *c* reductase activity of type VI apoprotein by successive incubation with protohæm and riboflavin phosphate. Activity tests were carried out as described by Morton and Shepley (ref 10), approximately 5 μgm of protein were used in each test

The recombination of the apoprotein and hæmin forms a hæmoprotein with an absorption spectrum which closely resembles that of type IV hæmoprotein-557. The re-activated protein formed by the further addition of riboflavin phosphate differs from the native type I cytochrome b_2 in that it is strongly fluorescent, and only a portion of the added hæmin is reduced by lactate. This is consistent with the finding of about 1 per cent of the cytochrome *c* reductase activity of cytochrome b_2 in the recombined material. In view of the established lability of cytochrome b_2[3,7], and the rather drastic conditions needed for the removal of the hæm group from the enzyme, it is unlikely that recovery of activity can be further increased. Details of these and related investigations will be reported elsewhere[22].

Selective inhibition of lactate-cytochrome c *reductase activity of cytochrome* b₂. Of a number of compounds recently tested by Hallett and Morton[23], most (such as arsenite and *p*-chloromercuribenzoate) caused similar inhibition of enzymic reduction of ferricyanide and of cytochrome *c* catalysed by type I cytochrome b_2. However, amytal at about 2·6 mM concentration caused a substantial inhibition of reduction of cytochrome *c* but had no similar effect on reduction of ferricyanide. Although the possibility of combination of amytal with cytochrome *c* has not been eliminated, this seems most unlikely. This selective inhibition supports kinetic studies of Armstrong and Morton[14,15] showing that the reduction of ferricyanide and of cytochrome *c* involves different mechanisms.

Discussion

Warburg and Christian[24] in 1932 isolated the first flavoprotein enzyme, and these workers, and Theorell[25], showed that the flavin group could be removed under acid conditions with loss of enzymic activity, which was recovered by recombination of flavin with the apoprotein.

The acid-acetone treatment developed by Hill and Holden[26] for preparation of globin from hæmoglobin was used by Theorell[27] in 1940 to remove the hæm prosthetic group of peroxidase. Recombination of apoprotein and hæmin was accomplished after incubation at room temperature for some hours, with recovery of enzymic activity[27].

In the case of cytochrome b_2, an enzyme discovered in 1942 by Dixon[1–3], activity has now been shown to depend on the presence of both flavin and hæm prosthetic groups. Since apoprotein-hæmin material added with apoprotein-flavin material is inactive, arguments for a flavoprotein-hæmoprotein pair in cytochrome b_2 (ref 4) can be dismissed.

Kinetic[11], inhibitor[23], and reactivation[22] investigations are consistent and confirm that reduction of ferricyanide (an artificial acceptor) and of cytochrome *c* proceed through different pathways, as proposed in 1955[6]. However, enzymic activity with any acceptor depends on the presence of the two prosthetic groups, which so clearly interact, and not on either group alone.

Cytochrome b_2 of yeast mitochondria is a distinctive type of dehydrogenase, having two molecules of riboflavin phosphate and two molecules of protohæm per enzyme molecule, together, riboflavin phosphate and protohæm constitute the essential prosthetic group of this enzyme

RESOLUTION OF PATHOLOGICAL HUMAN GAMMA-GLOBULINS BY STARCH-GEL ELECTROPHORESIS

By J. P BINETTE and K SCHMID*

Massachusetts General Hospital, Boston 14, Mass.

THE heterogeneity of the 7S normal human γ-globulins has been demonstrated by several techniques, including electrophoresis, convection, chromatography and biological assays[1-7] On starch-gel electrophoresis employing the continuous buffer system of Smithies[8], the γ-globulins are known to migrate towards the cathode as a broad zone In the discontinuous buffer system described by Poulik[9] most of these globulins move in the opposite direction The γ-globulins of pathological human sera, analysed by the 'continuous' gel electrophoresis technique, have been shown to migrate essentially as a single zone located in different positions within the area of the normal γ-globulins[10,11]

We report here the resolution by starch-gel electrophoresis of the γ-globulins of certain pathological sera into several distinct bands

The principal results of this work are presented in Fig 1 The distribution of the γ-globulins of the five representative pathological sera differed significantly from one other In the continuous borate buffer system these globulins of four of the five specimens migrated towards the cathode like the normal γ-globulins. The first pattern (Fig 1*a*) shows the starch-gel electrophoretic analysis of the serum from a patient with cancer of the ovary and widespread metastasis The remarkable finding is that the γ-globulins separated into seven bands The next pattern (Fig. 1*b*) represents the gel electrophoresis of the serum of a patient with probable chronic myeloid leukæmia The γ-globulins resolved into three zones of which the middle one appeared to be further separated into four sub-bands The pattern of the serum of a patient with hypergamma-globulinæmia of four years duration but without clinically detectable disease is shown in Fig 1*c* The γ-globulin zone appeared very dense compared with that of normal serum (Fig. 1*N*) although their areas were about equal The γ-globulins of another patient with unknown diagnosis displayed a similar pattern with three narrow heavy bands superimposed The γ-globulins of a further patient (Fig 1*d*) moved as a single rather narrow band to the cathode side of the normal γ-globulin area Comparable findings have been reported earlier[10,11] The fifth specimen was obtained from a patient with chronic normochromic normocytic anæmia of sixteen years duration It was interesting to observe that the γ-globulins migrated towards the anode, that is, in the direction opposite to that of the movement of the normal γ-globulins, and exhibited a pattern (Fig 1*e*) characterized by a very intensely coloured band in the slow α_2 ($S\alpha_2$) region (It is worth mentioning that this patient is not unusually prone to infections and, therefore, must still have the benefit of antibody protection) In addition, there were three minor zones distributed almost equally between the slot of application and the major γ-globulin band mentioned

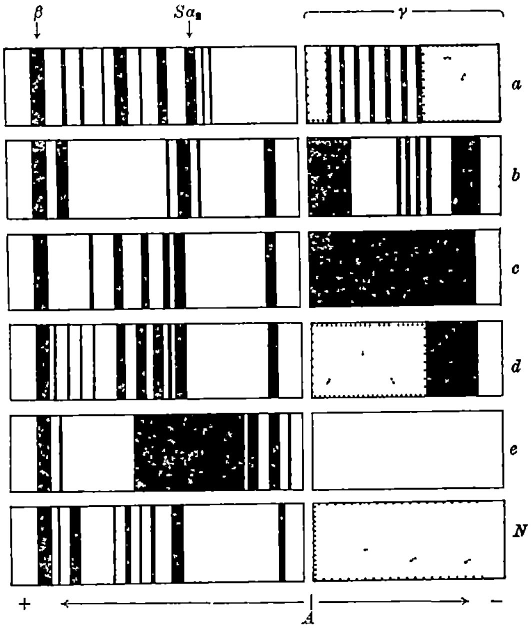

Fig 1 Starch-gel electrophoretic analysis of five pathological sera (*a–e*) For comparison the corresponding pattern of normal human serum (*N*) is included, and the positions of the γ- (γ) and slow α_2- ($S\alpha_2$) globulins and transferrin (β) are given The two arrows indicate the directions of movement of the proteins '*A*' points to the slots of application The starch-gel electrophoresis was performed in the cold room at 3° in *p*H 8 6 borate buffer at 20 m amp for 17 hr The part of the patterns that shows the transferrin–pre-albumin region is not reproduced

Use of the discontinuous system of buffers led to the following findings The γ-globulins of serum 1*a* entered the anodic side of the application slot and again separated into four bands which were located in the $S\alpha_2$ region It appeared that additional γ-globulin bands were present in the haptoglobin area Only traces of protein moved towards the cathode Under the same conditions normal γ-globulin (Cohn's Fraction II) formed a broad zone in the $S\alpha_2$-haptoglobin area and further bands in the post-albumin region[12] The γ-globulins of serum 1c displayed a pattern which was very similar to that observed in the continuous buffer system, except that a relatively smaller amount of protein seemed to be present, probably because the normal γ-globulins of this serum moved in the opposite direction The γ-globulins of patient 1*d* migrated as in borate buffer towards the cathode, but a separation took place which led to one minor band preceding and two following the main zone Moreover, additional lines were observed in the haptoglobin region The γ-globulins of patient 1*e* displayed a pattern which was essentially the same as the protein distribution observed in the continuous system Thus, judging from the behaviour of the γ-globulins of this limited series of sera, and as pointed out earlier by Poulik[13], the discontinuous buffer system leads to a higher resolu-

---

[*] Established investigator of the Helen Hay Whitney Foundation, New York

tion than that resulting from the continuous system Further, all γ-globulin bands obtained by the discontinuous system were located closer to the albumin zone as noted previously[13] Nevertheless, certain pathological γ-globulins (1*b*, *c*, *d*) still migrated towards the cathode

Paper electrophoresis at *p*H 8 6 in citrate barbiturate buffer of the sera investigated demonstrated in each case a significant increase of the proteins which migrated with mobilities corresponding to those of the γ-globulins The increase over the normal value was 23–34 relative per cent As judged by ultracentrifugal analysis the 7S-globulins of the same sera varied between 30 and 40 per cent The 19S-component appeared approximately normal in concentration Abnormal plasma proteins with sedimentation coefficients of 10 and 14S, respectively, were observed in one case (1*e*) only

The present starch-gel electrophoretic investigation on pathological γ-globulins demonstrates that this procedure offers an advantage over paper electrophoresis in that certain abnormal γ-globulins can be resolved into several bands This resolution seems to indicate that these pathological γ-globulins display a discontinuous spectrum with respect to apparent mobility in contrast to the continuous spectrum of the normal γ-globulins If the mobility of the 7S-γ-globulins may be related to the net charge of these molecules, then this observation can be interpreted to mean that certain pathological γ-globulins are synthesized in such a way that they carry relatively unlike electrostatic net charges

GAMMA-GLOBULIN AND ACQUIRED IMMUNITY TO HUMAN MALARIA

By Dr S COHEN

Department of Immunology, St Mary's Hospital Medical School, London, W 2

AND

Dr I A McGREGOR and S CARRINGTON

Medical Research Council Laboratories, The Gambia, West Africa

MALARIAL infection is followed by the development of immunity which is specific for the homologous parasite, but ineffective against heterologous strains and species[1–4] The epidemiological effects of acquired immunity in man are seen among the inhabitants of hyperendemic malarious regions who show a consistent pattern of susceptibility to infection Infants born in such regions are relatively resistant during the first three months of life and thereafter all children suffer severe and recurrent attacks of the disease Clinical malaria becomes comparatively infrequent in later childhood and among adults is rarely seen in acute form[5,6].

The response of phagocytic cells in malarial infection was shown in early histological work[7], and for many years resistance to the disease was considered to be exclusively cellular in nature In 1937, Coggeshall and Kumm[8] demonstrated the passive transfer of malarial immunity in rhesus monkeys and so established the presence of protective antibodies However, the therapeutic effect of large doses of immune serum was evident only against minimal numbers of parasites and has not been demonstrated convincingly in man The belief is therefore still prevalent that circulating antibodies play a relatively unimportant part in acquired malarial immunity[9]

Passive Transfer of Human Malarial Immunity

In this investigation the role of circulating antibody in malarial immunity has been studied in subjects living in The Gambia which is a hyperendemic area of West Africa The therapeutic effect of γ-globulin prepared from the serum of apparently immune adults has been tested in young African children suffering from severe clinical malaria with dense parasitæmia The γ-globulin prepared by chromatography on columns of diethylaminoethyl cellulose[10] was homogeneous on electrophoresis and in the ultracentrifuge appeared as a main peak with a sedimentation coefficient ($S^0_{20,W}$) = 6 78, an additional heavier component (10*S*) comprised less than 5 per cent of the total protein The remainder of the protein eluted from the columns (referred to here as γ-free serum) was shown by serological tests to contain about 70 mgm 7S γ-globulin and 20 mgm 19S γ-globulin/gm total protein

Twelve children aged 4 months–2½ years (weight 5 4–12 6 kgm.) admitted with a clinical diagnosis of malignant tertian malaria and an initial parasitæmia of 10,000–230,000/c mm received γ-globulin by intramuscular injection at intervals of 8–24 hr for 3 days The total dose was 1 2–2 5 gm /child which

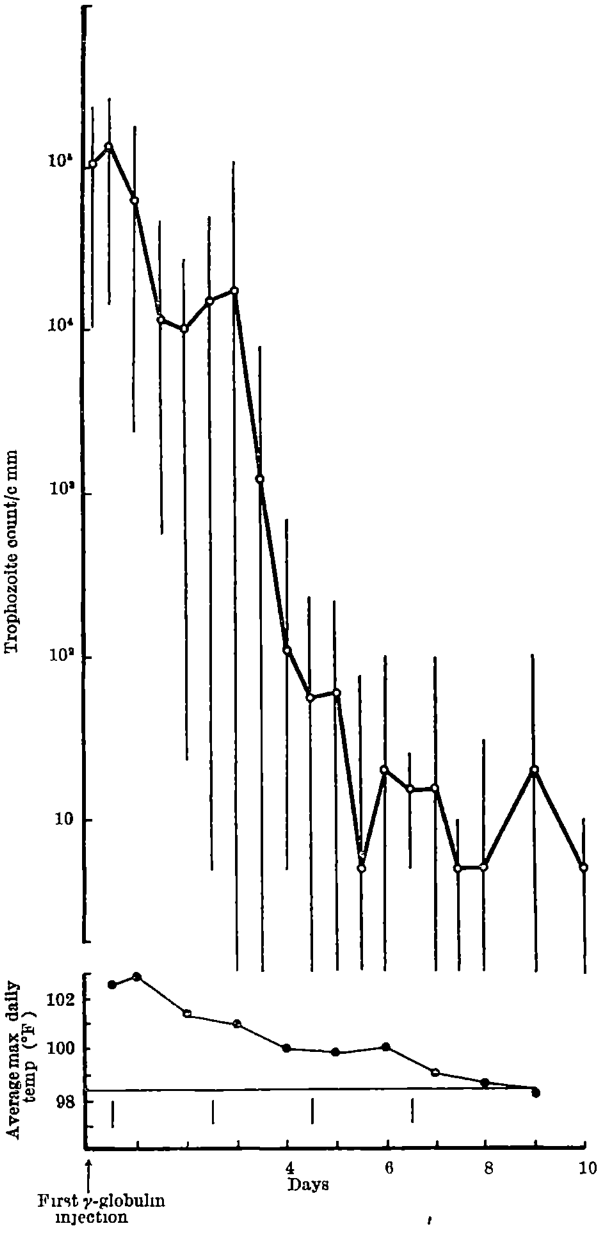

Fig 1 Trophozoite counts (mean and range shown on a logarithmic scale) and average maximum daily temperatures in 12 children with acute *Plasmodium falciparum* malaria treated with immune γ-globulin The time-scale refers to days after the first γ-globulin injection Vertical lines below indicate approximate times of expected schizogony

was equivalent to 10–20 per cent of the recipient's own γ-globulin

The infections were predominantly synchronous and γ-globulin therapy was usually started when the peripheral blood contained a high density of young ring forms Blood examinations were made at 12-hourly intervals and the course of parasitaemia is shown in Fig 1 By the fourth day after the inception of treatment parasite counts were always less than 1 per cent of the initial values, by the ninth day trophozoites were not detectable in 8 out of 12 cases and the maximum count was 80/c mm (Fig 1) The fall in parasitaemia was accompanied by progressive alleviation of clinical illness although temperatures did not usually return to normal before the seventh day (Fig 1) No alterations in parasite morphology have been observed during treatment; however, in malignant tertian infections only immature parasites are detectable in peripheral blood The immune γ-globulin appears to be effective both against *Plasmodium falciparum* and *P malariae* (Fig 2), but probably has no action against gametocytes (Fig 3)

Two children aged 2–3 years failed to respond to the injection of 1 2 gm γ-globulin They had been admitted with pneumonia and measles respectively,

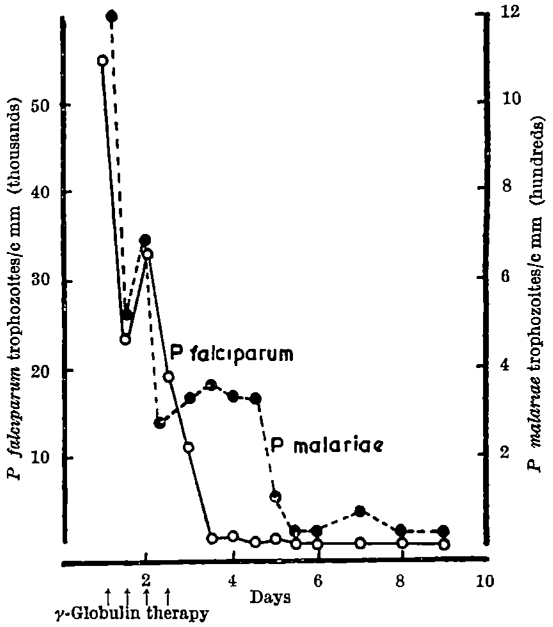

Fig 2 Trophozoite counts of *Plasmodium falciparum* and *P malariae* in a child with a mixed infection treated with immune γ-globulin, arrows show times of administration of γ-globulin by intra-muscular injection

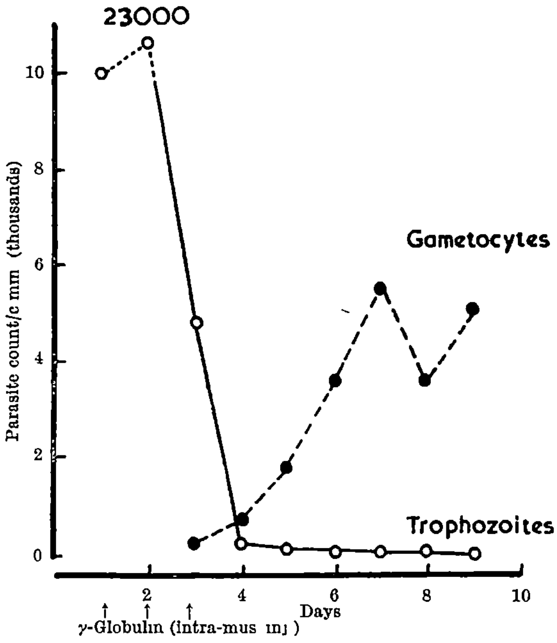

Fig 3 Trophozoite and gametocyte counts in a child with acute *Plasmodium falciparum* malaria treated with immune γ-globulin Arrows show time of administration of γ-globulin by intra-muscular injection

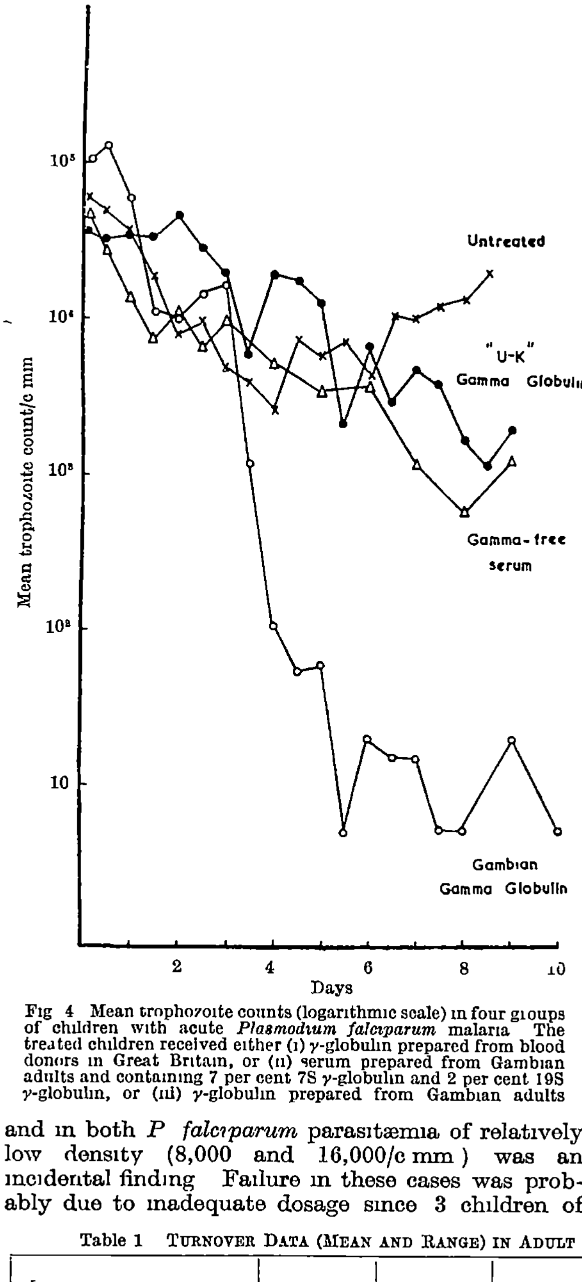

Fig 4 Mean trophozoite counts (logarithmic scale) in four groups of children with acute *Plasmodium falciparum* malaria The treated children received either (i) γ-globulin prepared from blood donors in Great Britain, or (ii) serum prepared from Gambian adults and containing 7 per cent 7S γ-globulin and 2 per cent 19S γ-globulin, or (iii) γ-globulin prepared from Gambian adults

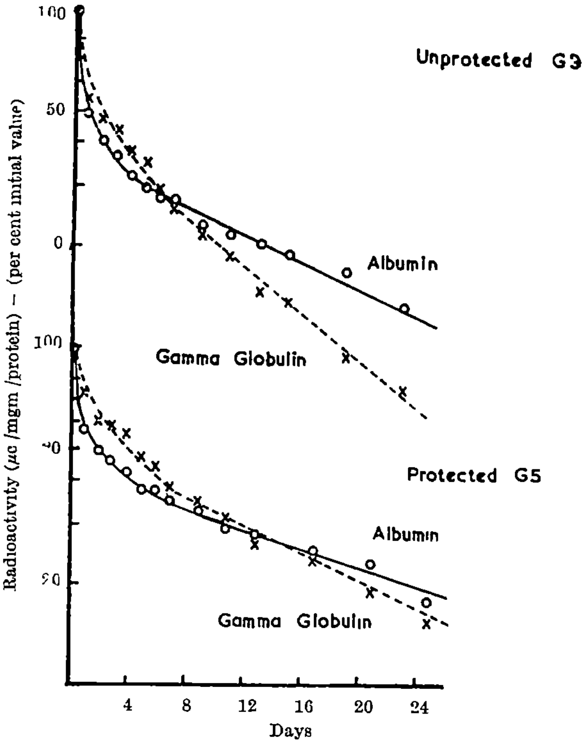

Fig 5 Plasma elimination of ^{131}I-albumin and ^{125}I-γ-globulin in an unprotected adult Gambian and in a similar subject who had received 'Pyrimethamine' (25 mgm /week) for 6 years

and in both *P falciparum* parasitæmia of relatively low density (8,000 and 16,000/c mm) was an incidental finding Failure in these cases was probably due to inadequate dosage since 3 children of comparable weight (10–12 kgm) responded to the injection of 1 8–2 5 gm γ-globulin

In further experiments, 7 children with acute *P falciparum* malaria received the γ-free fraction of Gambian serum (0 8–1 4 gm) A single batch was used in all experiments and no child has developed signs of serum hepatitis In addition, 4 children received γ-globulin prepared from the sera of blood donors in Great Britain (Lister Institute, Elstree, Herts) and 2 were kept under observation without anti-malarial therapy Trophozoite counts usually decreased in all these children However, the response was irregular, and between the fourth and tenth days the mean trophozoite counts were considerably greater than those observed after treatment with adult African γ-globulin (Fig 4)

γ-Globulin Synthesis in Relation to Malarial Infection

The distribution and turnover of separate plasma protein fractions can be measured simultaneously by using two isotopes of iodine (iodine-131 and iodine-125) having different γ-emission spectra[11] Using this method, rates of albumin and γ-globulin synthesis have been measured in apparently healthy Gambian adults exposed to malarial infection but not showing detectable parasitæmia Similar studies were carried out on 5 Gambian adults who had received an anti-malarial prophylactic weekly for 4–5 years (Fig 5) and also on 4 West African medical students who had suffered from malaria in childhood, but had been resident in England for 3–10 years The experimental procedure has previously been described[11,12], results were analysed according to the method of Matthews[13]

The rate of albumin synthesis was similar in the three groups of Africans and within the range for healthy Europeans On the other hand, the rate of γ-globulin synthesis in unprotected Gambians was about 7 times that observed in Europeans, protection by anti-malarial therapy considerably reduced the rate of γ-globulin synthesis (Table 1 and Fig 6) The rapid turnover of γ-globulin in unprotected adults cannot be attributed to the selective catabolism of isotopically labelled malarial antibody since γ-globulins prepared from European and adult Gambian donors have identical elimination-rates (Fig 7) Considerably less γ-globulin was synthesized by an unprotected subject who was three months pregnant at the time of study (Table 1), this finding is of interest in relation to the increased susceptibility to malarial infection described in pregnant women living in hyperendemic areas[14,15]

West Africans resident for some years in the United Kingdom synthesized less γ-globulin than Gambian subjects maintained on anti-malarial therapy (Fig 6), this difference must be attributed to environmental factors other than malarial infection After several years in Great Britain, West Africans continue to synthesize γ-globulin at almost twice the rate observed in healthy Europeans, this may be due to environmental influences of early life or to genetically determined differences in γ-globulin metabolism.

Mechanism of Acquired Malarial Immunity

The preparation of γ-globulin from pooled sera of apparently hyperimmune donors and the use of susceptible children as recipients likely to have been exposed to homologous parasite strains, have provided optimum conditions for demonstrating the potency of naturally occurring malarial antibodies active against *Plasmodium falciparum* and probably also against *P malariae* The results show that the mechanism of acquired malarial immunity is basically similar to that observed with many other infections, being primarily dependent on the presence of protective antibodies which are associated with 7S γ-globulin The response to immune γ-globulin

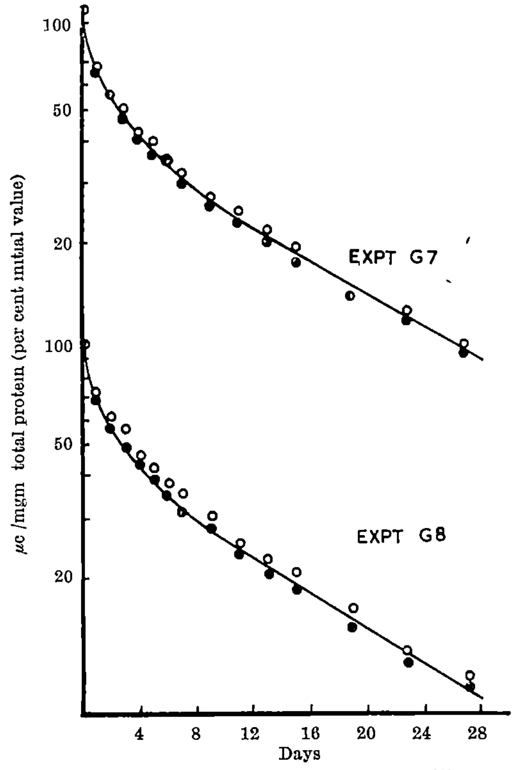

Fig 7 Comparison in two unprotected African adults of the plasma elimination of γ-globulin prepared from European and Gambian donors and labelled with iodine-125 and iodine-131 respectively. ●, European γ-globulin, O, Gambian γ-globulin

considered in relationship to the cycle of parasite development as well as the absence of morphological changes in the parasites of peripheral blood, suggest that antibody acts either on mature intracellular forms or on merozoites liberated from red blood cells Protection is of limited duration and a treated subject was again susceptible three months after receiving γ-globulin Other fractions of immune serum including 19S γ-globulin did not appear to have a protective effect nor did the γ-globulin of European blood donors

These findings support the hypothesis that the relative resistance of infants born in hyperendemic areas is due to passive transfer of protective antibodies from the mother This process may, however, be rendered relatively ineffective by partial loss of malarial immunity during pregnancy[14,15], which appears to be associated with a reduction in the rate of γ-globulin synthesis Other factors, such as selective vector biting[16], deficiency of *p*-aminobenzoic acid in milk-fed infants[17,18] and the presence of a high proportion of fœtal hæmoglobin in circulating red cells[19] may contribute to the suppression of malarial infection during early life

In areas of hyperendemic malaria, immunity is established only after long exposure to intense infection This slow response is probably attributable both to the inherently poor antigenicity of the parasite and to the serological diversity of naturally occurring plasmodia Acquired immunity is associated with hypergammaglobulinæmia[20,21] and with a striking increase in the rate of γ-globulin synthesis Protection of Gambian adults against malaria over a period of several years reduced the average daily synthesis of γ-globulin by 3 5 gm , which is more than the total daily production in healthy Europeans Since plasmodial infection leads to the production of complement-fixing antibodies[22] and precipitins[23], neither of which is species specific, it is likely that a considerable part of the γ-globulin synthesized in response to malaria is not protective antibody

We wish to thank Sir Charles Harington, whose interest led to the initiation of this work, and Prof R R Porter for much helpful discussion We are grateful to Dr D Harling for clinical supervision of patients, Dr W d'A Maycock for supplies of U K γ-globulin and Miss Margaret Polley for serological estimations of 19*S* γ-globulin One of us (S C) is in receipt of a Medical Research Council grant

MOISTURE EXPANSION RELATIONSHIPS FOR A FIRED KAOLINITE-HYDROUS MICA-QUARTZ CLAY

By Dr W. F. COLE

Commonwealth Scientific and Industrial Research Organization, Division of Building Research, Victoria, Australia

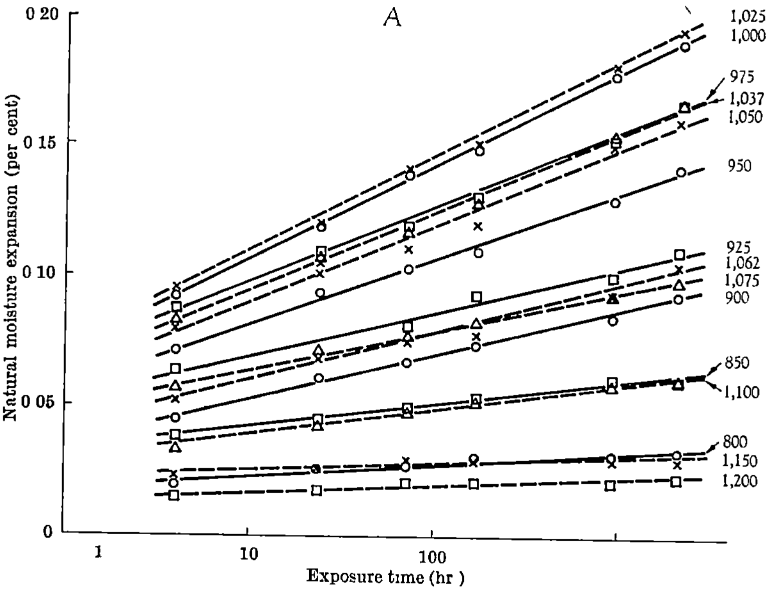
IN carrying out a detailed study of the moisture expansion characteristics of a clay containing 30 per cent kaolinite (poorly organized), 30 per cent hydrous mica (poorly organized) of the following approximate composition

$$[Si_{6\ 81}Al_{1\ 20}]\ [Al_{2\ 42}Fe_{1\ 16}Mg_{0\ 04}]$$
$$[Ca_{0\ 30}K_{0\ 25}Na_{0\ 15}H_3O_{1\ 42}]\ O_{20}(OH)_4$$

35 per cent quartz, 2 per cent hæmatite, and 1 per cent anatase, I have established relationships that might be found useful in interpreting the results from other clays and clay products

The curves of moisture expansion versus firing temperature for specimens exposed to air for 90 days, and for specimens autoclaved at 220 lb /sq in for 2, 8, 30 and 200 hr (measurements beginning from the same datum, specimens removed from the muffle at 300° C and cooled for 2 hr in a dry desiccator before initial measurement) show that the autoclave expansion curves parallel the natural expansion curve and that at a firing temperature of about 1,000° C all have a maximum in expansion If, however autoclave expansion is plotted directly against natural expansion (Fig 1), non-linear relationships exist over the firing range 950–1,200° C for all periods of autoclaving, and the points below and above 1 000° C separate into two curves for 30 and 200 hr of autoclaving (Linear relationships exist if autoclave expansion is plotted against the log of natural expansion) The non-linear relationship expresses the fact that for this clay the ratio of autoclave expansion to natural expansion varies widely with firing temperature, and implies that there must be several reactive components produced over the range of firing temperature covered by the specimens Mineralogical analysis has established that these reactive components are amorphous matter, glass, and anhydrous clay minerals Amorphous matter, which is responsible for the coincident moisture expansion peak at about 1,000° C in autoclaved and naturally exposed specimens, is equally reactive to water vapour in the air or to steam under pressure, but anhydrous clay minerals and glass are far more active to steam than to water vapour in the air Thus, for fired clay samples containing varying amounts of amorphous matter, anhydrous clay minerals, and glass, non-linear relationships must arise between autoclave expansion and natural expansion Furthermore, the nature of the anhydrous clay minerals and of the glass will determine whether the autoclave and natural moisture expansion peaks occur at the same temperature

It is well known that both natural moisture expansion[1,2] and autoclave moisture expansion[2-5] increase rapidly at first but in the later stages the increases are much slower The interesting feature of the new results is that a plot of natural expansion against logarithm of time (Fig 2*A*) is linear for all firing temperatures from 800 to 1,200° C and exposure times from 4 hr to 90 days A plot of the autoclave expansions against the log of the time of autoclaving (Fig 2*B*) shows also that a linear relationship exists for specimens fired at 1,000–1,150° C for autoclave times for 2–200 hr Similar relationships can be found from the data in the literature[2], if plots are made against log time rather than against time However, data on other clays from the Division[6] suggest that at times longer than those investigated here the logarithmic relationship breaks down and that the complete curve of expansion against logarithm of time is frequently *S*-shaped Consequently caution is needed in using the log-time or any other time relationship in predicting future values of moisture expansion from known results



Weight measurements made at the same time as expansion measurements show that as the temperature of the natural moisture expansion peak is approached from low firing temperatures, progressively less water is required to produce unit expansion, but that at temperatures beyond that of the moisture expansion peak the same weight of water produces the same amount of expansion The same is true for specimens expanded in the autoclave Furthermore, the amounts of water per unit expansion for specimens fired above the temperature of the moisture expansion peak are much the same for the natural (1 52 per cent increase in weight for a 1 per cent increase in length) and autoclave (1 92 per cent increase in weight for a 1 per cent increase in length) expansion, that is, the moisture absorbed in the two processes must be held in the same way However, there is a small amount of

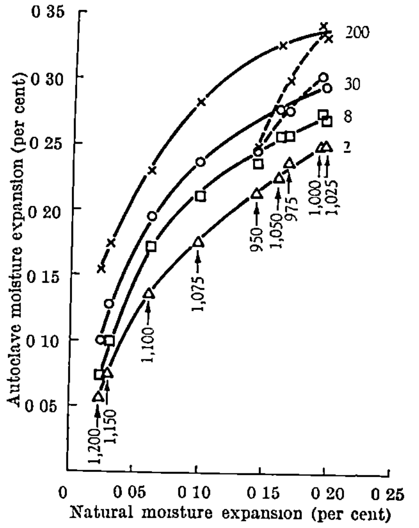


Fig 1 Autoclave moisture expansion on a dry basis after 2 8, 30 and 200 hr of autoclaving versus natural expansion after 90 days of exposure for specimens fired at 950–1,200° C The results for specimens autoclaved for 30 and 200 hr after being fired at 950, 975 and 1,000° C form separate curves which are shown by dotted lines

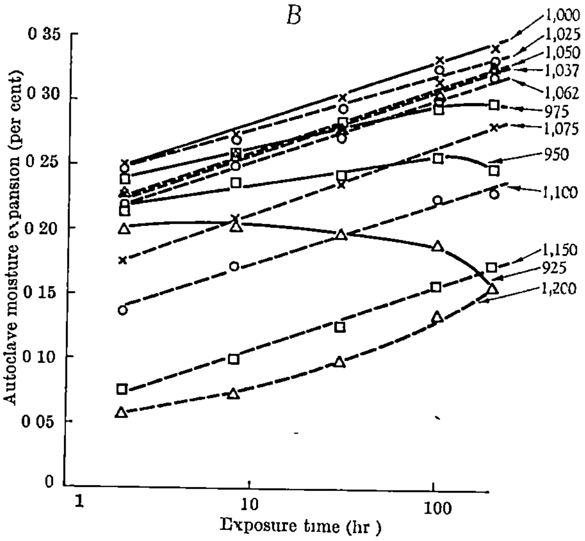

Fig 2 *A* Natural moisture expansion for specimens fired at 800–1,200° C plotted against the logarithm of time of standing in air Data for temperatures of 1,000° C or less are represented by full lines, data for other temperature by dotted lines
B Autoclave moisture expansion after drying at 110° C for specimens fired at 925–1,200° C plotted against the logarithm of the time of autoclaving Data for temperatures of 1,000° C or less are represented by full lines, data for other temperatures by dotted lines

water taken up in the autoclave which must be presumed to cause no expansion at all.

When specimens were desorbed up to a temperature of 500° C by re-heating, they lost weight and contracted, but at about this temperature those that were low-fired (600–900° C) showed an expansion with loss in weight which was not reversed until much higher temperatures of re-heating were reached. The magnitude of the expansion depended on the original temperature of firing and was only zero at a firing temperature of 950° C, that is, when the anhydrous mica was destroyed. Thus the expansion can be associated with the dehydration of the mica mineral regenerated from the anhydrous form by water sorbed after firing.

VISUAL EFFECTS OF NON-REDUNDANT STIMULATION

By PROF. D. M. MacKAY

Department of Communication, University College of North Staffordshire, Keele

OPTICAL fields modulated randomly with respect to space and time ('visual noise') appear to offer a powerful new tool for the investigation of visual perceptual processes. In earlier work[1,2] I have described the use of such 'non-redundant' stimuli to shock-excite the visual system during the inspection of regular spatially repetitive patterns, so as to reveal the 'complementary image' that is generated in the visual system by such patterns. The present article is intended as an interim report on a wider range of new visual phenomena revealed by the same technique. It is not concerned with exposure to random fields as a form of 'sensory deprivation', which has interesting effects in a different category[3].

A typical source of 'visual noise' is offered by a de-tuned television receiver with high gain. Most readers will be familiar with the 'snowstorm' effect thus produced on the screen. An alternative, which gives greater flexibility[4] is to make up a ciné film-loop from successive samples of a random distribution of white (or black) spots. (Photographs of sandpaper, or sprinkled confetti, are remarkably adequate.) With any such source, the following effects may readily be observed.

(1) *Discontinuity between foveal and peripheral fields.* The normal impression first created on inspection of visual noise is that of a homogeneous field of 'particles' in violent agitation. Individual 'particles' can be followed for a second or more in pseudo-Brownian motion. On prolonged inspection, however (especially if monocular), the foveal area of the field is clearly distinguishable from the remainder. Its motion is more coherent, as of a liquid boiling up from a restricted central source, and its average amplitude of pulsation is greater than that of the peripheral field. As the gaze is directed to different regions of the random stimulus, the 'boiling' foveal area can be clearly identified by the fact that it travels with the eye.

(2) *Monocular versus binocular viewing.* Considerable theoretical interest attaches to the contrast between monocular and binocular excitation. Most subjects spontaneously report that the monocular field appears the more densely populated, and scintillates more rapidly. With two eyes the field is seen as less 'sparkling', the motion more 'oily', the 'particles' fewer and more persistent. On most theories of binocular fusion it would not have been expected that the simultaneous and identical excitation of corresponding retinal areas should reduce the apparent density and frequency of what is perceived.

(3) *Effect of intensity.* One is led to ask whether simply halving or doubling the intensity of stimulation could produce the same effect as changing from binocular to monocular viewing or vice versa. But in fact rather the opposite is the case. At weak intensities the field appears much more 'oily' and is traversed by wriggling, interlocking snake-like shadow-patterns that may each extend over much of its area. At the normal intensity of a television screen, however, a change by a factor of 2 (or more) makes little difference. Binocular fusion here involves clearly more than the central summation of retinal impulses from 'corresponding points'. This is in line with the discovery by Jung[5] and others of separate cortical representations of each retina (in the cat).

(4) *Steady illumination in one eye.* It might be suggested that the occlusion of one eye causes centrifugal feedback, to both retinæ, which enhances the sensitivity of the unoccluded eye. As a partial test of this hypothesis the unused eye can be flooded with uniform illumination adjustable in brightness above or below the average level of the random source. The effect, however, is negligible, and not at all comparable with that of using both eyes to view the source.

(5) *The 'frame-adhesion' effect.* One of the most pleasing effects occurs when a portion of the random field is 'framed' within a movable contour such as the outline of a loop of wire. When the wire frame is moved and followed with the eye, the whole assemblage of 'Brownian particles' within it (and those immediately outside) are unmistakably seen to move with it. If the motion of the frame is rapid and oscillatory, the particles show a kind of inertia, lagging behind and swirling just as if immersed in a fluid.

When, however, a stationary object such as a finger-tip is placed within the framed area, practically the whole is suddenly stabilized, 'adhering' to the finger-tip. If the finger in turn is moved, it appears to be 'pursued' by a swarm of particles.

That the interactions concerned are central, rather than retinal, can be seen by presenting the noise to one eye and the frame to the other, when the effects are much the same, apart from a somewhat more noticeable time-lag in the coupling between frame and noise field.

(6) *Complementary images* As already reported[1] the effects of superimposing random noise on spatially repetitive patterns are especially striking When a source of noise is viewed through a transparency such as Fig 1, the otherwise chaotic disposition of the 'particles' is at once organized into one or several superimposed geometrical figures (the 'complementary image' (ref 1)) the principal directions of which run at right angles to the lines of the repetitive pattern A similar but transient reorganization' is seen if the random source is viewed alone, immediately after inspection of the repetitive pattern

The phenomenon is extremely tolerant of the optical definition of the random source Even with a thin sheet of paper between the pattern and the television screen, the complementary image is clearly visible An impression of a typical figure complementary to the stimulus of Fig 1 is shown in Fig 2 If the stimulus figure is a 'grid' formed by superposing sets of parallel lines at right angles, the complementary image lines run diagonally

The complementary figures so generated are generally seen in motion With Fig 1, for example, the subject typically reports two or more superimposed 'rosettes' of the type of Fig 2, which may be seen as contra-rotating, or all rotating clockwise or anticlockwise, more or less at will If Fig 1 is itself rotated, the complementary image rotates in the opposite direction

When Fig 3 is used, a petalloid radial complementary image is seen, with strong radial streaming along the petals In addition, however, there is a slow and steady rotation of the noise field, with an angular velocity, varying with the radius, of approximately one radian a second This turns out to be a quite distinct phenomenon, not dependent on spatial repetitiveness , for if visual noise is viewed through even a single annular aperture, it is still seen to rotate in each direction alternately

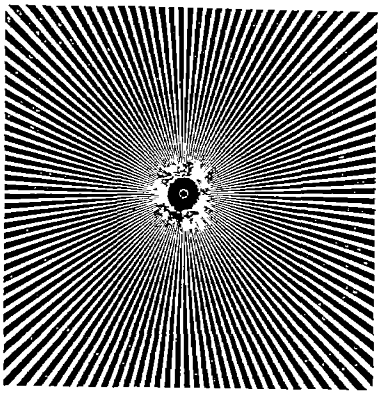

Fig 1

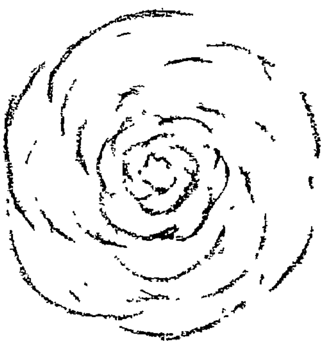

Fig 2

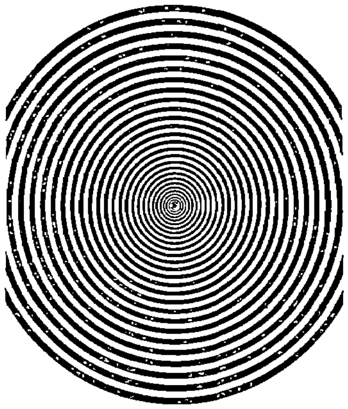

Fig 3

(7) *Implications* It is not my purpose here to advance interpretations of the phenomena described, on which we are working at present , but if they demonstrate anything clearly, it would seem to be the strong synthetic element in perception, which is present even when 'associations' in the usual sense might be expected to be absent What is seen under excitation by random noise bears only an approximate relation to the stimulus Instead, even against a blank background, it seems to be a fairly strongly structured synthetic 'imitation'—that is, a distribution of activity matched presumably in respect of certain statistical features, but sufficiently well structured for changes in its position to be readily attributable and easily perceived (Exp 5) With a background of a regularly periodic nature, the structure seen bears still less resemblance to that of the stimulus

The foregoing are only samples of the new data revealed by this way of 'shock-exciting' the visual system, which will be discussed more fully elsewhere The present article is intended mainly to direct attention to the power and potential value of this class of stimulus In communication engineering, random noise is often used as a 'neutral' test-signal to reveal the characteristic modes of response (resonances and the like) of an information-system In the study of the visual system it seems clear from the foregoing examples that visual 'noise' offers a tool with a corresponding ability to uncover some characteristic modes of response of perceptual mechanisms Formally, it can be regarded as the neutral member of a family of stimuli at the extremes of which are stroboscopic illumination (spatially uniform, temporally periodic) and our parallel-line patterns (temporally uniform, spatially periodic) At each of these extremes characteristic responses are also evoked[1,6], and it can scarcely be doubted that all three classes of phenomenon have something to contribute to our theorizing about perceptual processes

LETTERS TO THE EDITORS

ASTROPHYSICS

Presence and Correlation of Fine Structure in Jovian Decametric Radiation

JUPITER's non-thermal emission in the decameter region of the spectrum takes the form of sporadic radio noise storms having durations ranging from minutes to several hours[1]. Observers agree that the storms show fine structure, in part composed of bursts which typically have durations ranging from several tenths of a second to several seconds. However, there has not been agreement as to the presence of still finer structure or the intrinsic origin of any of the fine structure.

In 1956 Kraus[2] and Gallet[3] reported very short bursts having durations of tens of m sec or less, which they associated with Jupiter, but other observers[4-7] have been unable to confirm this. As for the origin of fine structure, radio sources of angular size much greater than Jupiter often show pronounced ionospheric scintillation with components occasionally as short as several seconds[8,9], the Jupiter source must be expected to show at least similar effects. Recordings made by Gardner and Shain[4] on three nights in 1956, using receivers spaced 25 km east–west, indicated little correlation of the noise fine structure over this base-line, the lack of correlation suggesting that ionospheric irregularities might account for much if not all of the burst structure. On the other hand, a spaced-receiver observation by us in 1958 (ref 10), while confirming the existence of considerable amplitude distortion, showed 80 per cent correlation in the time of arrival of bursts at stations separated by as much as 30 miles east–west. Florida–Chile observations in 1960 by A. G. Smith and Carr[11] also indicated partial correlation over a very long base-line, suggesting the reality of some intrinsic fine structure.

To resolve these questions a new series of base-line correlation observations was initiated by us in March 1961. Four identical crystal-controlled total-power receivers working at 22 200 Mc./s with 6 kc./s band-width were fed with identical antennas. The locations chosen were the Yale Observatory's Bethany Observing Station (central site), Hendrie Hall at New Haven (15 km south of Bethany), Van Vleck Observatory at Middletown (30 km east of Bethany), and Pomfret School (100 km east of Bethany). The audio outputs of the receivers were transmitted to Bethany on telephone lines. During Jupiter storms all four channels plus timing marks were recorded on a high-speed photographic recorder with a time constant of 30 msec. Records obtained on 19 nights up to August 1 exhibited various degrees of correlation, including 6 nights on which correlation was essentially perfect, without amplitude distortion. Correlation tended to improve through the Jupiter observing season from March onwards, suggesting that the phase with respect to Jovian opposition (July) or to the terrestrial season (summer) may be significant.

A small portion of a storm with correlated events (July 18) is reproduced in Fig. 1 (the New Haven receiver was not functioning during this run). Storms with similar portions of closely correlated events were observed on June 5 and July 11, 20, 27, and 30. No form of ionospheric effect is known that preserves its correlation over 100 km., accordingly we conclude that fine structure such as that of Fig. 1 is characteristic either of the source at Jupiter or of the interplanetary medium, but that this intrinsic structure is often largely obliterated by local ionospheric effects.

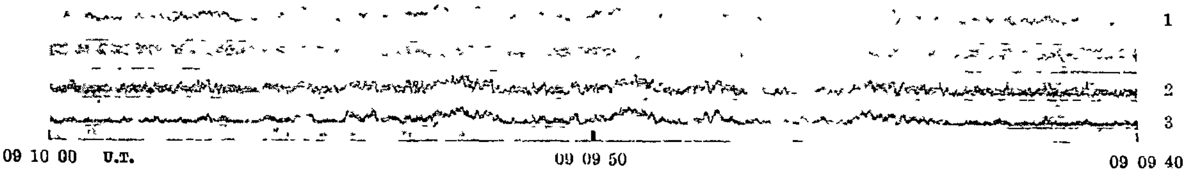

Fig. 1. A 20-sec portion of the high-speed recording of the Jupiter storm of July 18, 1961, showing close correlation of fine-structure events received at Middletown (3) and Pomfret (2) stations separated by 30 and 100 km. respectively from the Bethany Station (1)

During this observing season we noted the presence of numerous correlated fine-structure components having durations of hundredths rather than tenths of seconds. In comparison, our observations during 1960 showed no events having durations less than 0.1 sec. We must regard this extreme fine structure as real, in view of its correlation over long base-line and association with Jupiter storms (not present before or after). Thus the occasional existence of Jupiter bursts of extremely short duration as reported by Kraus and Gallet seems to be confirmed.

The co-operation and assistance particularly of E. Milone of Yale Observatory, Dr. F. Zabriskie of Van Vleck Observatory, J. McCullough of Pomfret School, and financial support from the National Science Foundation are gratefully acknowledged.

GEOPHYSICS

Confirmation of Outer Atmospheric Asymmetry postulated to explain the False Zodiacal Light

IN 1952 and afterwards[1-3], I suggested that the false zodiacal light—an early morning pyramid of light above the western horizon, resembling the zodiacal light which at that time would be on the opposite side of the sky—might be explained if Earth's gaseous tail were driven off mainly from the western twilight rim of the globe I can now point to some recent findings that support this idea[4,5]

A terrestrial gaseous tail has been repeatedly postulated (by Lomonosov in 1753, Houzeau in 1888, Evershed in 1902, Astapovich[6], Fesenkov[6], Divari[6], and many others) to explain the counterglow or gegenschein, an antisolar luminosity with a variable brightness and a gaseous emission spectrum (Karimov[6], Tikhov), which Soviet parallax measurements place at an apparent distance of ~ 20 Earth radii The gases forming such a tail could only be of atmospheric origin, presumably solar radiation pressure carries off atoms or molecules thermally expelled in high trajectories from the underlying denser atmosphere I pictured "the solar heating steadily unwinding a ribbon of gas from the upper atmosphere into the ecliptic plane" (ref 2, p xviii)

The false zodiacal light, observed and named by Divari and Fesenkov in 1946 (ref 6, p 22) but previously described by Sykes[7] and by Schmid[7], is presumably a luminosity in the lower part of the tail, below the counterglow The counterglow luminescence is thought to be excited by solar corpuscular emission in the region beyond the terrestrial magnetosphere (Astapovich[6]) To-day one may suspect that the nearer luminosity of the false zodiacal light is connected with the van Allen radiation, though other theories are possible[1,2,6]

Most remarkable is the asymmetry of the false zodiacal light it is seen in the western sky as a post-midnight opening-out of the counterglow ellipse, but it is never seen in the eastern sky If the gaseous tail itself is asymmetric, the reasons could be that (*a*) the rotation of Earth assists the solar radiation pressure at the evening twilight rim of Earth, but opposes it at the morning twilight rim, (*b*) at the evening twilight rim the atmosphere has been heated by the Sun, so that the supply of thermally accelerated exospheric particles, that is, the density of the exterior atmosphere, would here be significantly greater than on the morning rim (ref 2, p xvi)

Point (*b*) is now confirmed by the exospheric densities calculated from the orbital behaviour of artificial satellites Beginning at ~ 200 km height above the terrestrial ellipsoid, there is a minimum of density at 6 hr true local time and a maximum at 14 hr The difference between maximum and minimum steadily increases with altitude, and at 1,700 km, according to the model used by Romer[5], it exceeds two orders of magnitude At 18 hr the pressure remains high, at 700 km height the supply of gas particles is ~ 7 5 times greater on the evening rim than on the morning rim of Earth (ref 4, Fig 4), at 1,700 km it is ~ 12 times greater (ref 5, Fig 2)

The exterior atmosphere is chiefly maintained by solar energy absorbed and stored at lower (*F*-layer) levels This explains the lag of the density maximum toward the afternoon and the continuing higher density in the evening

The false zodiacal light, seen only in the west, must not be confused with the zodiacal twilight[8,9]—the atmospheric component of the ordinary zodiacal light—which according to Divari's specific finding appears with equal intensity on the western and eastern horizons Moreover the zodiacal twilight is concentrated toward the horizon, while the false zodiacal light, opening out from the counterglow (Divari[6], Fig 10), is strong at higher angles of elevation

It is also obvious that the false zodiacal light, extending from the counterglow, is unrelated to the cosmic dust-cloud component of the ordinary zodiacal light Aside from the nearness, the variability and the emission spectrum of the counterglow as demonstrated by the Soviet authors, there is Roach and Rees's demonstration[10] that the counterglow and the cosmic zodiacal light lie in slightly different planes The former is, as expected, in the ecliptic, while the cosmic dust cloud is symmetrical with a plane through the Sun determined mainly by Jupiter's gravitation[11] (Long-lasting confusion has been caused by the reports of those who profess themselves unable to find the slightest asymmetry or variability of the zodiacal light with respect to the ecliptic These reports may be dismissed as pointless, because there is no imaginable reason why the zodiacal dust cloud around the Sun should lie precisely in the ecliptic, which is merely the orbital plane of the Earth)

BIOPHYSICS

Extendability of Tendons undergoing Contraction-Relaxation

EQUILIBRIUM melting of tendons[1] and collagenous tissues[2] follows the theoretical behaviour expected for a first-order phase transition Thus, the ordered crystalline regions of polypeptide chains disintegrate into randomly oriented coils of the amorphous phase Rat-tail tendons subjected to melting by lyotropic agents undergo rapid contraction followed by relaxation to rupture, and these physical events are easily measured characteristics of the melting process Stress-strain curves of thermally shrunk tendons have been shown to obey equilibrium elastic theory for amorphous polymers[3], for example, stress is proportional to $(\alpha - \alpha^{-2})$, where α is the strain This communication deals, however, with a kinetic analysis of melting of rat-tail tendons in concentrated aqueous urea at *p*H 7 0 and 37° C

When the velocity of length-time observations (Fig. 1) was analysed kinetically, equation 1 was found to agree with the data The terms involved are dL/dt, the velocity of change of length at any time (t), $(dL/dt)_c$, the initial velocity of contraction, $(dL/dt)_r$, the terminal velocity of relaxation, and K_{cr}, the specific rate-constant

$$\text{Log}\,[dL/dt - (dL/dt)_r] = \log\,[(dL/dt)_c - (dL/dt)_r] - K_{cr}t \quad (1)$$

Temperature had a pronounced influence on the rate process, but it systematically followed equation 2

$$\text{Log}\,K_{cr} = A + B/T \quad (2)$$

The resistance to disruption of ageing tendons in 10 M urea solution, furthermore, increased according to equation 3

$$\text{Log (time-to-break)} = C + D(\text{age, or weight of animal}) \quad (3)$$

Generally, it is believed that the attack on collagen by urea breaks stabilizing hydrogen bonds[4] A complication in the selectiveness of this protein–urea interaction is that a condensation can occur between free amino groups of the protein with a slight amount of ammonium cyanate which exists in equilibrium with aqueous urea[5] This should not, however, interfere with hydrogen bond rupture, in fact it could promote it by assisting to liberate one conjugor (amine side-chains of lysine or hydroxylysine) from a previously existing hydrogen bond with those groups It has also been shown that aqueous urea condenses with long hydrocarbon side-chains to form 'adduct' compounds[6] Since collagen in tendons has few such long hydrocarbon side-chains, it does not appear that adduction of urea presents any great complication

Accepting that action of urea results in rupture of secondary, tertiary, and higher-order —OH stabilizing bridges[4], we investigated next how this depolymerization influenced tendon elasticity To answer this question experiments were conducted in which the momentary extension of a tendon was measured by adding and removing a weight. A change in length ($\Delta L'$), illustrated in Fig 1, was determined periodically and superimposed on the contraction–relaxation sequence Fig 2 shows a plot of strain $(1 + \Delta L'/L)$ as a function of contraction–relaxation time

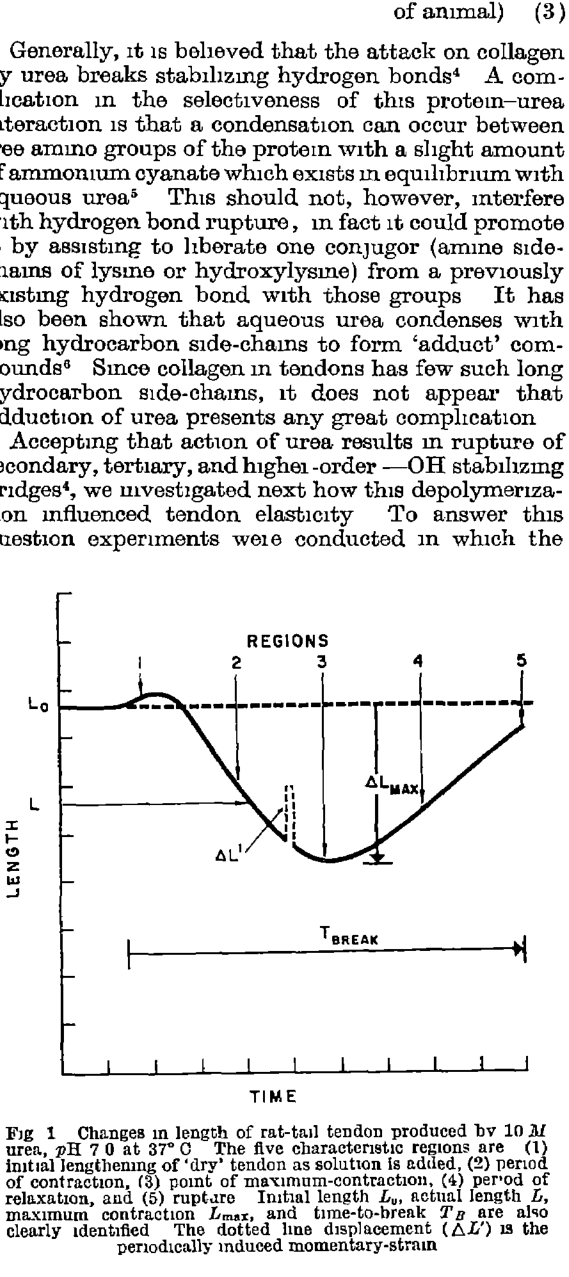

Fig 1 Changes in length of rat-tail tendon produced by 10 M urea, pH 7 0 at 37° C The five characteristic regions are (1) initial lengthening of 'dry' tendon as solution is added, (2) period of contraction, (3) point of maximum-contraction, (4) period of relaxation, and (5) rupture Initial length L_0, actual length L, maximum contraction L_{max}, and time-to-break T_B are also clearly identified The dotted line displacement ($\Delta L'$) is the periodically induced momentary-strain

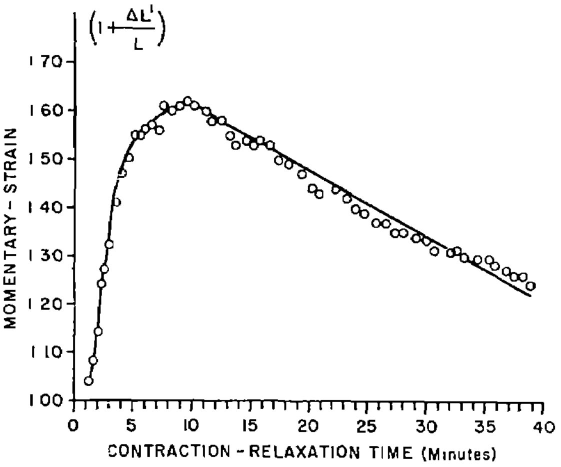

Fig 2 Dependence of momentary-strain $\left(1 + \frac{\Delta L'}{L}\right)$ on time of contraction–relaxation

Figs 1 and 2 reveal that a tendon becomes more easily extendable as a result of the action of urea which also produces shortening and re-extension Maximum extendability occurs near the point of maximum contraction, and it decreases with subsequent lengthening of the tendon It is obvious, therefore, that extendability and contraction–relaxation are inversely related

The change of strain with time $\frac{d}{dt}(\Delta L'/L)$ was evaluated and plotted as a function of time Numerous graphs of these data suggested that there was a semi-logarithmic relationship between velocity of strain and time A final graph was made of the difference between velocity of strain at time (t) and that constant velocity of strain which characterized the relaxation period A linear relationship was observed with this function, and equation 4 was derived on the basis of these numerical analyses

$$\text{Log}\left[\frac{d}{dt}(\Delta L'/L) - \frac{d}{dt}(\Delta L'/L)_r\right] = \log\left[\frac{d}{dt}(\Delta L'/L)_c - \frac{d}{dt}(\Delta L'/L)_r\right] - K'_{cr}t \quad (4)$$

These measurements of the rate of increased tendon extendability during contraction support the interpretation that the latter reflects a crystalline/amorphous phase transition, or melting It is not clear, however, why extendability and re-extension are inversely related because the tendon is continuing to degrade to the point of rupture A maximum degree of shortening would appear to be theoretically possible but this may not be realized due to possible independence of $(dL/dt)_c$ and $(dL/dt)_r$ Consideration of factors responsible for incomplete shortening and relaxation might lead to a better understanding of the kinetic mechanism of contraction–relaxation Finally, this could give a more precise explanation of effects of ageing on rate of tissue dissolution such as shown by equation 3

METALLURGY

New Ternary *R*-Phases with Silicon

THE *R*-phase was first found[1] in the chromium–molybdenum–cobalt ternary system. Its crystal structure has been determined by Shoemaker *et al* [2] Additional *R*-phases were later found in the molybdenum–manganese–cobalt and molybdenum–manganese–iron ternary systems[3], as well as in the titanium–manganese binary system[4] Recently, in the investigation of several ternary systems with silicon a number of new *R*-phases have been identified Table 1 gives the approximate composition and the lattice parameters of these new *R*-phases

Table 1 COMPOSITION (APPROXIMATELY) AND LATTICE PARAMFTERS OF NEW *R*-PHASES

Alloy	Annealing temperature (° C)	*c* (Å)	*a* (Å)	*c*/*a*
$Ti_2Mn_{79}Si_{19}$	1,000	19 23	10 87	1 77
$Nb_5Mn_{79}Si_{16}$	1,000	19 28	10 89	1 77
$Ta_5Mn_{79}Si_{16}$	1,000	19 19	10 86	1 77
$Mo_3Mn_{78}Si_{19}$	1,000	19 18	10 85	1 77
$W_3Mn_{78}Si_{19}$	1,000	19 22	10 86	1 77
$V_{37}Fe_{41}Si_{22}$	1,100	19 23	10 79	1 78
$V_{45}Co_{40}Si_{15}$	1,100	19 14	10 78	1 78
$V_{45}Ni_{40}Si_{15}$	1,100	19 10	10 82	1 77

It is interesting to note that in all alloys as yet known to consist of the *R*-phase one of the component elements has a relatively large co-ordination number 12 atomic radius in relation to that of the others For example, in all the *R*-phases listed in Table 1, the ratio of the co-ordination number 12 radii of the two transition elements lies between 1 07 and 1 12 In the case of the ternary *R*-phases with manganese and silicon the concentration of the element with the large atomic radius needed in order to stabilize the *R*-phase may be quite small, for example, 2 *a*/*o* titanium, 5 *a*/*o* niobium or tantalum, 3 *a*/*o* molybdenum or tungsten However, the amount of vanadium required in the ternary systems with iron, cobalt or nickel and silicon is very much larger

It has now been established that the unidentified phases previously designated as I, III and V co-existing with the σ-phase in the vanadium–iron–silicon, vanadium–cobalt–silicon and vanadium–nickel–silicon systems[5] are identical with the corresponding *R*-phases listed above Previously unidentified phases II and IV also co-existing with the σ-phase in the vanadium–iron–silicon and vanadium–cobalt–silicon systems have now been identified as having the α-Mn structure An α-Mn phase also occurs in the vanadium–nickel–silicon system Details of these phase relations will be published

α-Manganese Phases containing Technetium-99

THE existence of α-manganese phases in the zirconium–technetium, niobium–technetium and molybdenum–technetium systems was recently reported by V B Compton *et al* [1] During the course of our investigation of alloy phases involving technetium-99 with transition metals, α-manganese phases were found in the binary systems scandium–technetium, titanium–technetium, hafnium–technetium and tantalum–technetium Pertinent information is given in Table 1 The alloys were made by arc-melting transition metals of high purity with technetium-99 X-ray data were obtained from specimens in the as-cast condition with a powder camera of 114 6 mm diameter using filtered copper radiation

Table 1 LATTICE PARAMETERS OF SEVERAL α-MANGANESF PHASES CONTAINING TECHNETIUM-99

System	Alloy composition, atomic per cent	X-ray data a_0 (Å)
Sc–Tc	87 5 Tc, 12 5 Sc	9 509 ± 0 001
Ti–Tc	87 5 Tc, 12 5 Ti	9 579 ± 0 001
Hf–Tc	87 5 Tc, 12 5 Hf	9 603 ± 0 001
Ta–Tc	83 3 Tc, 16 7 Ta	9 565 ± 0 001

Crystal structure and lattice dimensions of technetium-99 have already been reported by R C L Mooney[2], using a microgram specimen He found a hexagonal close-packed structure with $a_0 = 2\ 735 \pm 0\ 001$ Å, $c_0 = 4\ 388 \pm 0\ 001$ Å, $c/a = 1\ 604$ In the present investigation lattice dimensions of technetium-99 were obtained from an annealed needle of high-purity technetium-metal The dimensions are as follows $a_0 = 2\ 743 \pm 0\ 001$ Å, $c_0 = 4\ 400 \pm 0\ 001$ Å, and $c/a = 1\ 604$ Since Mooney reported a slight impurity in his mixed sample, the lattice parameters reported here are probably more accurate

A Cold Crucible for High-Temperature Melting Processes

Exploratory research in the solid-state field has resulted in the development of a new melting technique for the processing of silicon. Although this method has been associated primarily with the purification of silicon and its growth as single crystals, it has important applications in the more general field of metallurgy.

In our earlier work[1], a container was made from a silver tube by pressing a longitudinal dent into its surface for most of the length. This silver 'boat' was internally water-cooled and contained a silicon bar in the depression. When power was applied to a short radio-frequency coil surrounding a small part of the boat, a narrow molten zone was formed in the bar. This zone was traversed along the bar to zone-refine the silicon and leave only the impurity boron, which does not segregate appreciably in silicon. The silver boat acts as a radio-frequency transformer, and current is induced into the silicon bar from the silver underneath it, as well as from the primary coil above it. The liquid silicon does not wet the cold silver surface; it should be emphasized, however, that melting is complete, without any skin or shell of solid silicon.

The results of pinch effect caused by mutually opposing electric currents can be observed following changes in the power setting or movements of the coil. Partial levitation of the melt can be obtained with suitably designed coils, particularly at a frequency of 500 kc./s. or lower; but at frequencies of 2 Mc./s. and above, these magnetic effects are very much reduced.

Another form of horizontal boat which has certain advantages in special cases can be made by using several straight parallel tubes mounted in a semicircle and closely spaced, so that the melt is confined in the boat by its surface tension.

The growth of silicon single crystals has been accomplished in the past by pulling from silica crucibles or by means of a crucible-free method (see, for example, ref. 2). The methods suffer from some disadvantages; in the former method, oxygen is introduced into the growing crystals due to chemical reaction between molten silicon and silica; in the latter procedure the density of dislocations tends to be high, and the diameter of the crystal is limited in size. Some attempts were made to grow single crystals horizontally in the silver boat, but these failed mainly on account of the large temperature gradient at the solid/liquid growing interface.

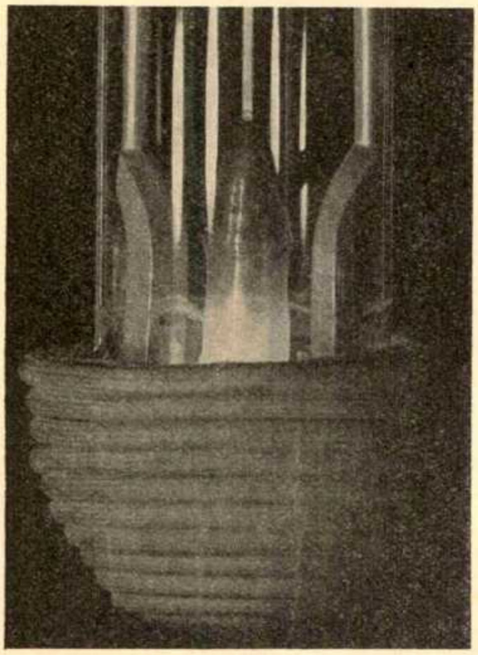

Fig. 1. A silicon single crystal grown from a cooled silver crucible

In order to obtain a more favourable thermal symmetry and a correct temperature distribution for the growth of single crystals, several novel types of crucible[3] have been designed. In one particular form (Fig. 1) a number of tapered and water-cooled silver tubes is arranged vertically, and curved inward at the bottom to join at their narrow ends and form a basket. This crucible is water-cooled internally, and mounted inside a radio-frequency primary coil which has the shape of an upturned skep. Power is induced through the spaces between the tubes, and also by induction due to the current which flows circumferentially in each tube. The tubes are placed sufficiently close together to prevent the melt, when formed, from escaping. Again it is important to note that melting is complete, and that no thin skin of silicon remains as in 'skull melting'.

Single crystals of silicon which are oxygen-free and dislocation-free have been grown by the Czochralski method from crucibles of this and similar types, using silicon which was obtained by the thermal decomposition of pure silane gas[4]. Life-times up to 1 msec. have been measured and resistivities greater than 1,000 ohm cm. have been preserved. Electrical and radiochemical tests have not detected the presence of silver in these crystals.

The cold-metal crucible has been also successfully used as a non-contaminating container for the melting and processing of such materials as ferrites and allied oxides, rare earth metals, molybdenum, titanium, uranium and boron; it is not restricted to high-temperature melting applications only.

We wish to acknowledge the work of Mr. F. J. Raymond, who is a co-inventor, and also other assistance given by colleagues of Standard Telecommunications Laboratories, Ltd., who are associated with this project. RADIOCHEMISTRY

Organic Extraction from Fused Uranium Chlorides

Fused plutonium and uranium chlorides may be a good nuclear fuel for a fast breeder reactor[1–4]. The aim of the present work is to investigate some chemical properties of fused chloride components, in particular, the presence of dissociated or associated or non-ionic molecules, and the possibility of using the liquid salt–liquid organic extraction. Some recent results concerning the extraction processes with fused

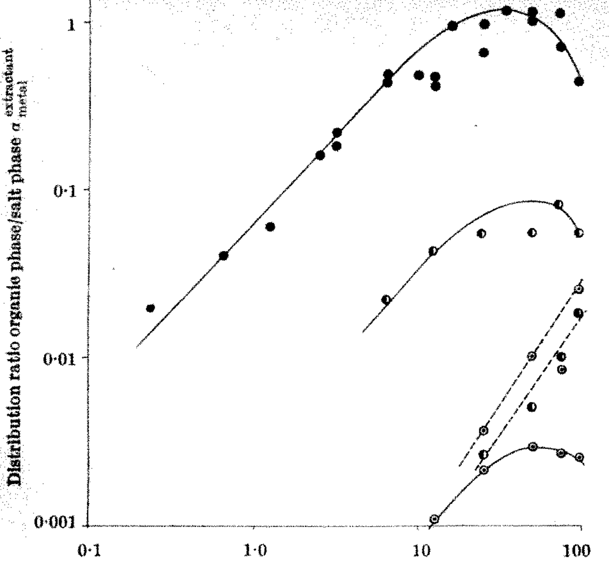

Fig. 1. ●, Uranium; ◐, copper; ⊙, potassium ——, TOA; - - -, TBP

salts are presented in ref. 5. In the present investigation the salt phase contains: diluent (nuclear non-active): eutectic mixture of KCl–CuCl, 1 : 2 molar ratio, and fissionable material: uranium tetrachloride (prepared by the reaction, uranium dioxide + carbon tetrachloride at 450° C.) with a concentration of uranium tetrachloride of 1·5 per cent w/w. The salts were dried under vacuum by heating and fusing in the presence of dry hydrochloric acid and dry argon, at a temperature of 180° C. The organic phase contains: diphenyl as diluent and one of the following extractants: tri-*n*-octylamine (TOA), tri-*n*-butylphosphate (TBP), di-*n*-butylphosphoric acid (HDBP); dried in vacuum by heating. All components of fused salts were used as labelled atoms: copper-64, potassium-42, chlorine-36, uranium enriched, registered by suitable radiometry α, β, γ. The extraction process was carried out in a small volume, 1·6 ml., in 180° C., for 30 min. (15 min. with shaking): after separation of both phases (using different solidification temperature) they are dissolved: salt phase in nitric acid solution, organic phase in toluene or benzene. All operations were performed in glove boxes with dried atmosphere. The distribution ratio $\alpha^{\text{extractant}}_{\text{metal}}$ for each metal is measured as ratio of total radioactivity of organic phase to salt phase (the volume ratio of the two phases is approximately 1). The results are shown in Fig. 1.

The experimental distribution ratios are as follows:

uranium: $\alpha^{\text{TBP}}_{\text{U}} \geqslant \alpha^{\text{HDBP}}_{\text{U}} \geqslant \alpha^{\text{TOA}}_{\text{U}}$

copper: $\alpha^{\text{TOA}}_{\text{Cu}} \gg \alpha^{\text{TBP}}_{\text{Cu}} > \alpha^{\text{HDBP}}_{\text{Cu}}$

potassium: $\alpha^{\text{TBP}}_{\text{K}} > \alpha^{\text{TOA}}_{\text{K}}$

TOA: $\alpha^{\text{TOA}}_{\text{U}} \gg \alpha^{\text{TOA}}_{\text{Cu}} \gg \alpha^{\text{TOA}}_{\text{K}}$

TBP: $\alpha^{\text{TBP}}_{\text{U}} \gg \alpha^{\text{TBP}}_{\text{K}} > \alpha^{\text{TBP}}_{\text{Cu}}$

From these results, it may be concluded that: in fused chlorides there are cations K^+ and Cu^+; non-ionic molecules, CuCl, Cu_2Cl_2 and potassium chloride; anions, $Cu_2Cl_3^-$, UCl_5^-.

For the CuCl–TOA extraction system, with a small concentration of TOA: $0·1\ M \leqslant$ concentration TOA $\leqslant 0·3\ M$, the ratio of molar concentration, copper/TOA in the organic phase is about 1 : 3, which corresponds to the formula $[TOACu^+]\ [Cu_2Cl_3^-]$. It also seems that for uranium tetrachloride–TOA extraction the extractable species is an ion-pair, namely, $[TOACu^+]\ [UCl_5^-]$.

A Simple Microdiffusion Technique for the Radioiodination of Proteins

A NUMBER of methods for the radioiodination of proteins and amino-acids have been described[1,2]. Some have relied on transfer of elemental iodine from an oxidizing medium by extraction with an organic solvent ; in others oxidation of iodide to iodine has been effected in the presence of the material to be iodinated with the associated risk of damage to the latter by the oxidizing reagent in the mixture.

Many of these techniques are somewhat cumbersome; moreover, some are such that little confidence can be felt either in the purity and integrity of the product or in the safety of the experimenter.

Faced with the task of labelling insulin with iodine-131 at high specific activity (~ 100 mc./mgm.) we have used Conway's microdiffusion technique[3], using in the first instance No. 2*a* diffusion units and more recently modified cells of smaller (~ 1 cm.). diameter. The technique has also been successfully applied to the radioiodination of beta- and gamma-globulins, albumin and tyrosine.

The material to be iodinated, dissolved in 0·2 *M* borate buffer (*p*H 8·0), is placed in the central chamber of the unit ; radioiodine diluted with the desired amount of inactive carrier is placed in the outer compartment together with an appropriate volume of acidified dichromate. Diffusion of iodine vapour into the central compartment is largely complete in a matter of 2 hr. (80–90 per cent is a typical recovery in most cases) although the exposure may be terminated at any desired time by addition of excess alkali to the outer chamber. Adequate distribution of iodine through the protein solution is effected either by agitation of the unit or by use of a small magnetic stirrer in the central compartment.

The maximum permissible volume of the oxidizing mixture is critically dependent on the weight of carrier iodine available for transfer. Where μgm. quantities of protein are to be iodinated, adequate transfer-rates of the μgm. amounts of iodine usually desired in these circumstances can only be obtained using oxidizing mixture volumes of a few microlitres. This places a lower limit on the amounts of protein of less than 5 μgm. which may conveniently be used, and hence indirectly on the specific activities which may be obtained with tolerable starting amounts of iodine-131. Nevertheless, specific activities of the order of 100 mc./mgm. insulin can readily be achieved using about 3–5 mc. iodine-131.

Radiochemical purity of the iodinated protein has been checked by electrophoresis and, in the case of insulin, by chromatography in a secondary butanol/

acetic acid solvent system[4]. No loss of biological activity of the iodinated insulin was observed using the rat epididymal fat pad bioassay technique.

Overall recovery of radioactivity in the final product has been of the order of 25 per cent. Though this implies considerable wastage of iodine-131, it has been felt that the advantages in this method of the mildest possible oxidative environment for the protein and the minimal radiation damage to which the latter is exposed compared with other techniques merit its application in many circumstances.

CHEMISTRY

Pyrolysis and Gas Chromatography for the Detection of the Benzene Ring in Organic Compounds

In a systematic investigation concerning the correlation between structure and pyrolysis products, it was found that pyrolysis of compounds eluted from gas chromatographic columns could be used for the detection of the benzene ring when present in organic compounds.

A conventional gas chromatograph was used in the experiments. The top of the column was provided with a heated quartz tube filled with 'Chromosorb' (about 2 gm.). Silicon oil was used as stationary phase.

The quartz tube was connected to a short thick-walled glass capillary with silicone rubber tubing. The capillary was closed with a serum-cap and the carrier gas was led into the column through a side tube just behind the serum-cap. The quartz pyrolysis tube was surrounded by a small furnace of which the temperature was measured with a thermocouple between the walls of the furnace and the pyrolysis tube. The compound under investigation was injected through the serum-cap in the usual way on to the hot 'Chromosorb'. Of liquid compounds 1 µl. was injected. Of solid compounds 5–10 µl. of a solution of the compound in methanol was used.

Some 100 different aromatic compounds containing a benzene ring were tested, and experiments with benzyl alcohol, benzylbenzoate and benzyl phenylacetate are shown in Fig. 1 as characteristic examples. It is seen that two peaks are present in the chromatograms. One peak was identified by infra-red spectroscopy as benzene, the other as toluene. This behaviour is characteristic for compounds that contain the benzene ring and a side-chain or groups such as —OCH_3 or —$OOCH_3$. The formation of toluene in these cases may be explained on the basis of free radical mechanism in which methyl radicals are formed from the —OCH_3 and —$OOCH_3$ groups respectively. This is made evident by the following experiment. When a saturated solution of benzoic acid in methanol is pyrolysed a small toluene peak is observed following a large benzene peak. When, however, a saturated solution of benzoic acid in chloroform instead of methanol is pyrolysed no toluene peak is found. A small peak with the correct retention time of chlorobenzene now appears next to benzene. For the compounds tested the ratio of the peak areas is a typical constant for the compound which is pyrolysed when the experimental conditions are kept identical (Table 1).

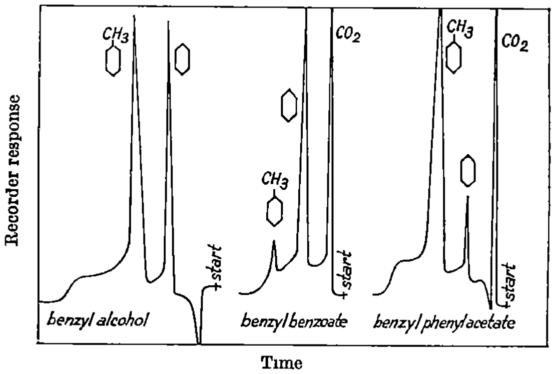

Fig. 1. Chromatograms of pyrolysis products of benzyl alcohol, benzyl benzoate and benzyl phenylacetate

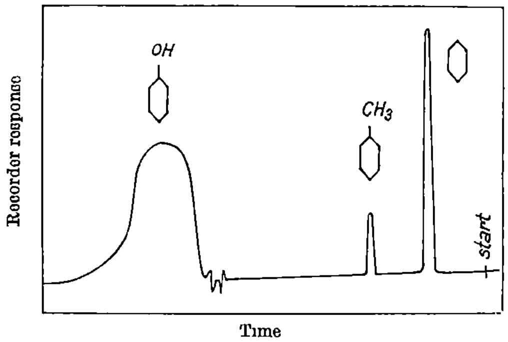

Fig. 2. Chromatogram of the pyrolysis products of anisole

The result of the pyrolysis of anisole is shown in Fig. 2. The formation of phenols was always observed in the pyrolysis of compounds containing the C_6H_5O-group such as salicylic acid (pyrolysed in methanol solution), *p*-cresylacetate, anisole and others.

The formation of benzene and simple benzene derivatives on pyrolysis of aromatic compounds was thus found to be a very general reaction for these compounds. Although it is known that benzene can be synthesized from simple aliphatic compounds by pyrolysis, no benzene peaks were observed when aliphatic compounds were tested under normal conditions. Aromatization clearly is negligible under the conditions used.

During the experiments recorded here separate series of tests on minute amounts of simpler organic

Table 1. Ratio of Peak Areas at Pyrolysis Temperature 550° C.

Compound	Area of toluene peak / Area of benzene peak
Toluene	7·5
Toluene	6·9
Toluene	7·9
Benzyl alcohol	1·7
Benzyl alcohol	1·7
Benzyl alcohol	1·8
Benzyl phenylacetate	5·4
Benzyl phenylacetate	4·9
Benzyl benzoate	*c.* 0·12
Benzyl benzoate	*c.* 0·12
Anisole	*c.* 0·127
Dioctyl phthalate	*c.* 0·08

compounds such as aliphatic alcohols, amines, acids and esters were pyrolysed and analysed in the way described From all these compounds characteristic chromatograms of the pyrolysis products were obtained which made it possible to differentiate between compound groups, individual members of homologous series and between isomers such as normal- and iso-alcohols

It is believed that a valuable technique for identification of the small amounts of material eluting from gas chromatographic columns can be based on this method of pyrolysis

The method does not seem to be restricted to volatile compounds[1]

A Coating with Antifouling Properties from the Reaction between Cuprous Oxide and Sodium Silicate

Films prepared from dispersions of zinc dust in sodium silica media of a high silica ratio of about Na_2O $SiO_2/1$ 3 8 by weight (Pass, A , and Meason, M J F , private communication) have been reported to become substantially insoluble in water within a few hours without the aid of curing agents previously needed to produce satisfactory air-drying zinc silicate paints[1] The mechanism of the formation of these films is only partially understood, and in the course of work undertaken to elucidate it, changes in viscosity occurring when zinc and other pigments are dispersed in silicate media are being examined

Various pigments were dispersed in aqueous solutions containing 16 6 per cent of sodium silicate having an Na_2O SiO_2 ratio of 1 · 3 55 by weight, and the changes in viscosity of the dispersions with time were measured at a shear-rate of 54 sec $^{-1}$ using a Couette co-axial cylinder type viscometer

Fig 1 shows curves which illustrate the viscosity/time relationships characteristic of the two main groups of pigments which were studied Dispersions of non-reactive pigments such as talc, micaceous hæmatite, titanium dioxide and iron oxide decrease in viscosity with time due to an improvement in dispersion brought about by the action of the viscometer Films produced from these dispersions will only become insoluble in water on long exposure in air or by the application of heat or curing agents In contrast, the viscosity of dispersions of some other pigments including zinc dust, cuprous oxide and mercuric oxide increases gradually with time evidently because the pigments react with or cause a reaction in the medium Of particular interest was the indication that, as with zinc, films of cuprous oxide in sodium silicate media of a high silica ratio might cure unaided at room temperature and this has been confirmed by experiment

The proportion of cuprous oxide in the dispersion and the Na_2O SiO_2 ratio in the medium can be varied over quite a wide range, and the film will still become insoluble in water within, at most, an overnight drying period Methyl cellulose, bentonite, micronized mica and similar viscosity control agents can be included to improve the application and film-forming properties of the dispersion A typical composition having satisfactory film forming and curing properties is made by dispersing 225 parts by weight of cuprous oxide and one part of methyl cellulose in 140 parts of an aqueous solution containing 18 6 per cent of sodium silicate having an Na_2O SiO_2 ratio of 1 3 8

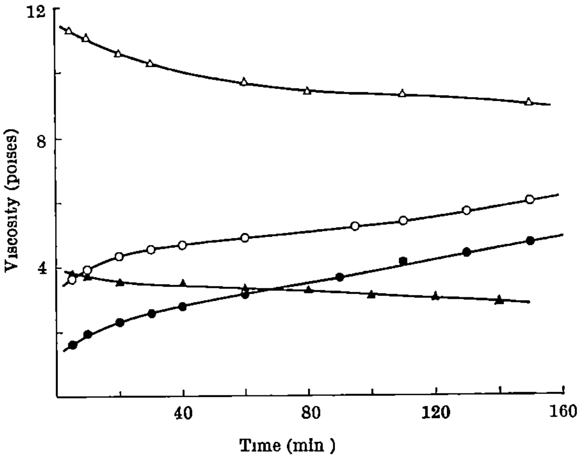

Fig 1 Viscosity at constant shear-rate as a function of time △, Talc, ○, cuprous oxide, ●, zinc dust, ▲, micaceous hæmatite The quantities of pigment added to 120 ml of sodium silicate solution were 56 gm , 225 gm , 450 gm and 300 gm respectively

Films of this composition and of variants of it have shown no fouling during a period of 95 weeks immersion in Sydney Harbour, Australia The most abundant macrofouling organisms recorded at this severe exposure site are *Balanus* (*Balanus*) *amphitrite* var *cirratus* Darwin, *Bugula avicularia* L , *Bugula neritina* L , *Hydroides norvegica* Gunnerus, *Spirorbis* sp , *Watersipora cucullata* (Busk), *Conopeum reticulum* (Linne), *Mytilus planulatus* Lamarck and *Crassostrea commercialis* Iredale and Roughley, and settlement of at least three of these species took place on inert control panels during each month of the immersion period (ref 2 and Wisely, B , private communication) The average fouling-free life of 46 commercial paints immersed along with the silicate compositions was 26 weeks (Laurie, H A , private communication)

There are indications that the inclusion of zinc dust up to the extent of about 10 per cent of the cuprous oxide content of such dispersions may prolong the fouling-free life of the film by depressing the solution-rate of the copper in the early stages of immersion

We thank the Department of the Navy, Australia, for the use of its immersion facilities in Sydney Harbour and Mr. H A Laurie for the periodic examination of panels The work forms part of a programme sponsored by the Department of the Navy, and this communication is published by permission of the Chief Scientist, Department of Supply, Australian Defence Scientific Service, Melbourne, Victoria, Australia

Evolution of Hydrocarbons from Impure Titanium Getters

When titanium getters are heated and evaporated in vacuum hydrocarbons are formed from carbon and hydrogen impurities in the metal[1] The evolution of hydrocarbon gases from two grades of titanium has been investigated in this laboratory with an 'Omegatron' mass spectrometer and found to be related to the partial pressure of hydrogen in the system and the carbon impurity in the getter

Two grades of titanium were used having the following chemical analyses and termed here grade *A* 0 055 per cent carbon, 0 0065 per cent hydrogen and grade *B* 0 007 per cent carbon, 0 016 per cent hydrogen Getter filaments were made by twisting together a titanium wire of 1 mm diameter and 5 cm long with three tungsten wires each of 0 5 mm diameter The getter filaments were mounted within glass cylinders (8 5 cm diam × 8 cm high) inside the stainless steel vessel of a bakeable high-vacuum plant The vessel was exhausted by a diffusion pump charged with silicone 704 and fitted with a liquid-nitrogen trap All the vacuum seals were made with metal gaskets and after baking the system an ultimate pressure of 10^{-8} torr was obtained To raise the partial pressures of the gases evolved by the getter, and thereby aid their detection by the 'Omegatron' spectrometer, the speed of pumping the vessel was limited to 10 l /sec by a diaphragm in the mouth of the liquid-nitrogen trap

When either grade of titanium was evaporated in high vacuum the principal hydrocarbon gas formed had a mass of 15 (CH_3) However, when the titanium was volatilized in hydrogen at a pressure of 10^{-7}–10^{-6} torr (nitrogen equivalent) the predominant hydrocarbon formed had a mass of 16 corresponding to the saturated compound of methane Subsequent experiments were then made with hydrogen leaked into the vessel during pre-heating of the getter, evaporation of titanium and after film deposition Mass spectra were recorded of the atmosphere in the system during each of these three stages A typical experiment was completed in a total time of 70 min with a pre-heating time of 40 min and an evaporation time of 15 min

To ensure that impurities in the tungsten heater did not influence the experiments bare tungsten filaments were heated in the same manner as titanium-loaded filaments, and the resulting mass spectra

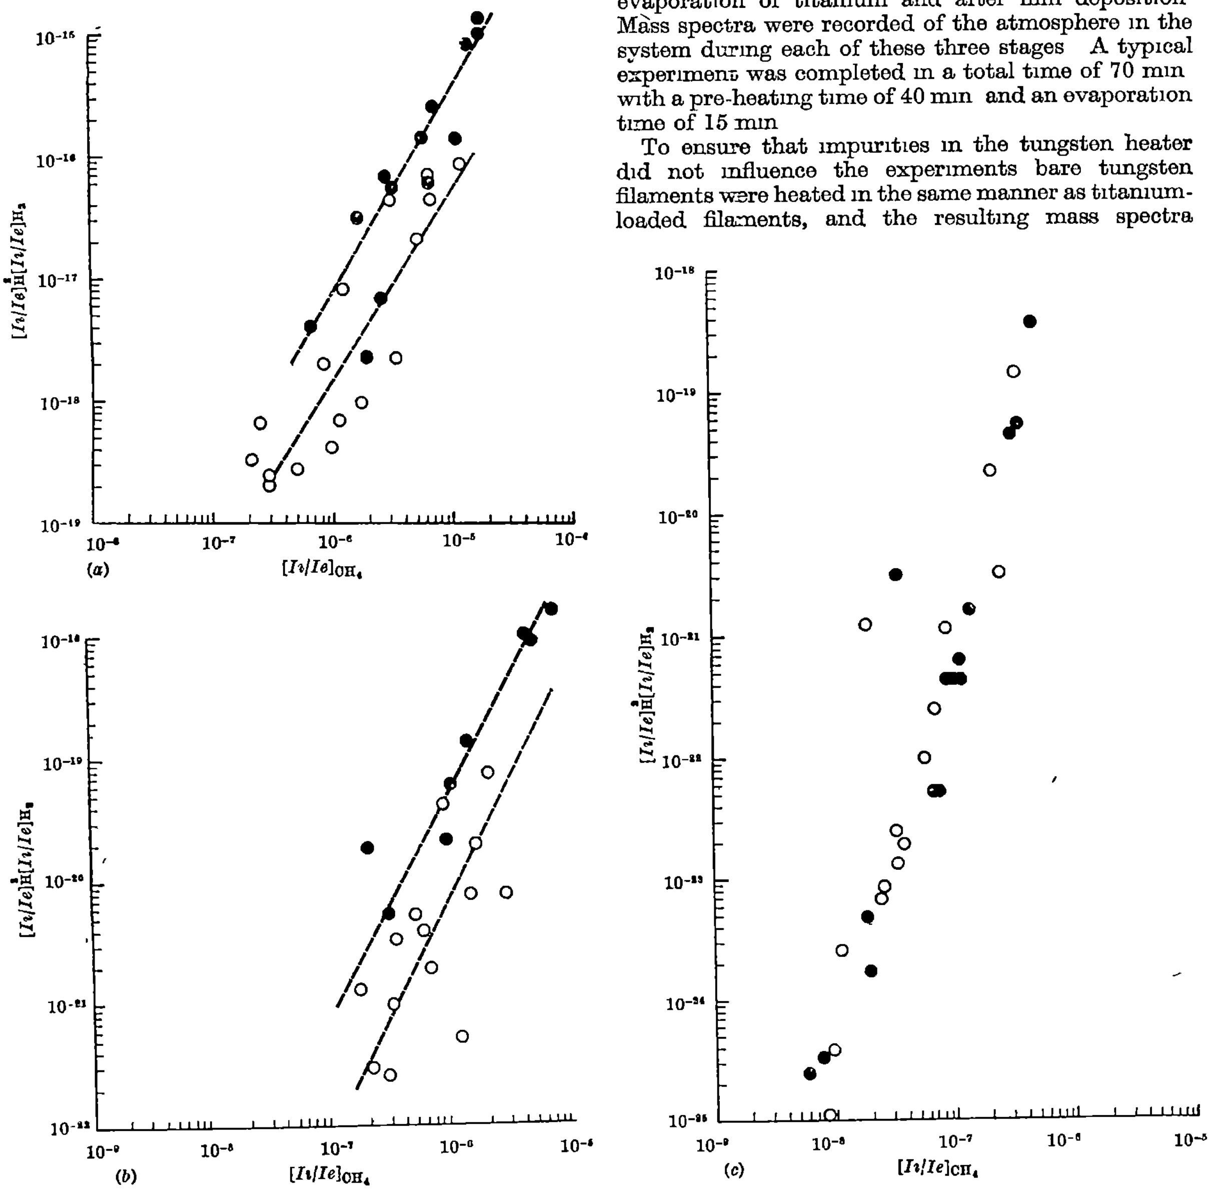

Fig 1 *a* ○, Type *A*, before evaporation, ●, type *B*, before evaporation *b* ○ Type *A*, during evaporation, ● type *B*, during evaporation *c* ○, type *A*, after evaporation, ●, type *B*, after evaporation $[I_i/I_e]$ is the ratio of ion to electron current showed that negligible amounts of hydrocarbon gas were evolved.

To find the relation between the partial pressures of hydrogen and hydrocarbon gas in the titanium experiments, the peak heights of atomic hydrogen, diatomic hydrogen and methane in the mass spectra were measured. Corrections were made to the measured values for variations in rate of evaporation during film growth and for changes in hydrogen concentration during the recording of the mass-spectra. The hydrocarbon evolution during the pre-heating and evaporation of the getter indicated that it followed the law of mass action if one assumed a simple equation of the kind $C + 2H + H_2 \rightleftharpoons CH_4$. Thus by plotting methane concentration $[CH_4]$ as a function of $[H^2][H_2]$, Figs. 1*a* and 1*b* were obtained for the pre-heating and evaporation stages respectively and empirical lines drawn through the points showed an approximately linear relation between $[CH_4]$ and $[H^2][H_2]$. The plotted values are divided into two groups in each graph, dependent on the carbon content of the getter metal. The partial pressure of hydrocarbon gas measured during the post-evaporation stage (Fig. 1*c*) did not show a dependence on the carbon impurity in the titanium. Also, the curve following the values in Fig. 1*c* departs more markedly from a linear relation between $[CH_4]$ and $[H^2][H_2]$ and the mass action law is not considered to apply.

During pre-heating the reversible chemical reaction between carbon and hydrogen must occur at the surface of the hot titanium. However, when evaporation begins it is uncertain whether the reaction can still proceed at the high filament temperature ($\geqslant$ 1,625° C.). It is possible that the reversible reaction now occurs at the surface of the condensing titanium film. At the pressure of operation ($\simeq 3 \times 10^{-7}$ torr) hydrogen molecules strike the titanium film at a rate of $4·5 \times 10^{14}$ molecules sec.$^{-1}$ cm.$^{-2}$ and rough calculations of the rates of arrival of titanium atoms give values between 1·5 and $5·0 \times 10^{15}$ atoms sec.$^{-1}$ cm.$^{-2}$. Thus the ratio of impinging titanium atoms to hydrogen molecules varies from 3 : 1 to 10 : 1. The heat released at the surface by the condensing titanium and the heat radiation from the getter filament may both be responsible for a reversible reaction at the getter surface.

Although there are many aspects of the foregoing work which are unsatisfactory, for example, the sole consideration of methane production ignoring other hydrocarbon species, it does show that metal film getters will only be completely effective in the sorption of hydrogen if they are prepared free from carbon.

Acknowledgments are made to Mr. Elwell, Division chief analyst of Imperial Chemicals Industry, Metals Division, and to Mr. Webb, chief analyst of Johnson Matthey, for their kind assistance in the chemical analysis of the titanium used in these experiments. Detection of Carboxyl Groups in Conjugation with the Porphyrin Ring System

THE band positions in the visible region of a porphyrin spectrum are influenced by the electrophilic nature of the substituents conjugated with the porphyrin ring system, the more electrophilic the substituent the farther the absorption maxima lie towards longer wave-lengths. Thus, when a reagent reacts specifically with a particular group to produce a derivative which has significantly different electrophilic characteristics, a corresponding change in the spectrum is observed, and this change indicates the presence of the group in question. For example, porphyrins with carbonyl groups conjugated with the ring system react with hydroxylamine to produce oximes which have their absorption maxima at wave-lengths shorter than those of the original carbonyl compounds. Such a spectroscopic change indicates the presence of a carbonyl group in conjugation with the tetrapyrrolic ring system. Methods of this type, which require only a trace of material, have played an important part in the structural determination of naturally occurring porphyrins.

My recent work has required a similar procedure for the detection of a carboxyl group in conjugation with the porphyrin ring system. It has been argued that since the position of the absorption maxima of porphyrins is dependent on the electrophilic nature of their substituents, the visible spectrum of a carboxylic acid, when in conjugation with a tetrapyrrolic ring system, should be different from that of its anion. Since the spectra of porphyrins in alkaline solution are often ill-defined, it has been found advantageous to carry out the present investigation on a series of pyridine hæmochromes (ferrous complexes of porphyrins, co-ordinated through iron to pyridine). These derivatives have well-defined two-banded spectra in alkaline media, and the position of the longer wave-length band (α-band) is particularly sensitive to changes in the electrophilic nature of the particular substituent conjugated with the porphyrin ring system. However, hæmochromes are stable only in alkaline solutions, and to provide a spectrum which would approximate that of the un-ionized acid, the methyl ester was used instead of the free acid, which under the alkaline conditions would be ionized.

The pyridine hæmochromes have been prepared by dissolving the porphyrin iron complex in pyridine 0·1 *N* sodium hydroxide (1 : 1) and reducing the mixture with sodium dithionite. Table 1 records the α-band position of pyridine hæmochromes derived from porphyrins containing a conjugated carboxylic acid group and compares them with values obtained from the corresponding methyl esters. A difference of more than 10 mμ between these values is observed, which provides a reliable diagnostic test for the presence of a carboxylic group in conjugation with the tetrapyrrolic ring system.

Table 1

Compound	α-Band of pyridine hæmochrome (mμ)	
	Acid	Ester
2-Carboxyl-deuteroporphyrin *	549	563
2-Carboxyl-4-vinyl-deuteroporphyrin *	555	567
2,4-Dicarboxyl-deuteroporphyrin *	554	567
4-Acrylic acid-deuteroporphyrin (ref. 2)	561	572
Rhodoporphyrin (ref. 3)	553	566
Porphyrin *a* acid (ref. 4)	560	572

* These compounds were prepared by oxidation of the corresponding formyl porphyrin, using Jones's reagent (ref. 5).

Fischer and Orth[1] quote a value of 563 mμ for the α-band of a hæmochrome derived from rhodoporphyrin In view of the values reported here their result appears anomalous and seems to approximate that of the ester rather than of the acid

Examination of Side-Chain Interactions in Poly-L-Tryptophan

WHILE hypochromism has been examined quantitatively by Tinoco[1] for polynucleotides and Imahori and Tanaka[2] have reported decreased extinction of the peptide absorption band at 1900 Å in poly-L-glutamic acid in the helical conformation, it was of interest to examine interactions of the aromatic side-chains of poly-L-tryptophan The results of absorption and fluorescence studies of the polyamino-acid compared with a suitable model for the monomer are discussed in this communication

Poly-L-tryptophan, having an average molecular weight of 17,800, was supplied by Dr Michael Sela Acetyltryptophan is commercially available and tryptophan ethyl ester was prepared by a modification of the method of Brenner and Huber[3] Solvents were distilled prior to use except for dimethylformamide, which was 'Spectroquality' reagent purchased from Matheson, Coleman and Bell Absorption spectra were taken with a Cary recording spectrophotometer model 14, and intensities of emitted light were measured with the Aminco-Bowman fluorometer with the monochrometers set at constant excitation and emission wave-lengths

The limited solubility of polytryptophan did not permit examination over a wide range of solvent polarities In this work the solvents used were dimethylformamide, dimethyl sulphoxide and *n*-butylamine/water (9 1 by vol) Poly-L-tryptophan absorption obeys Beer's law in these solvents over the twenty-fold range of concentration studied The absorption maxima and their extinction coefficients are shown in Table 1 together with the results of Hurd and Bauer[4] for polytryptophan (average molecular weight 4,000) in ethanol

The total areas under the absorption curves as a measure of the oscillator strength, *f*, were determined after extrapolation below 2600 Å , where accurate measurements were not obtainable because of solvent absorption The *f*'s are very nearly the same for acetyl- and poly-tryptophan in the solvents used in this investigation Similarly, temperature variation between 25° C and 80° C had no exclusive effect on the absorption spectrum of the monomer or polymer

Table 1 ABSORPTION MAXIMA AND EXTINCTION COEFFICIENTS OF *N*-ACETYL- AND POLY-TRYPTOPHAN

Solvent	*N*-Acetyltryptophan		Poly-L-tryptophan	
	λ_{max} (Å)	$\varepsilon \times 10^{-3}$*	λ_{max} (Å)	$\varepsilon \times 10^{-3}$
Dimethylformamide	2830 2910	5 99 5 35	2830 2910	5 84 5 13
Dimethyl sulphoxide	2835 2910	5 68 5 16	2835 2910	5 74 5 15
n-Butylamine/water (9 1 by volume)	2840 2915	5 58 5 07	2840 2915	5 43 5 10
Ethanol	2825 (ref 5) 2905	5 62 4 90	2820 2905	5 49† 4 68

* These values are the average of 10–15 determinations and are ± 0 05

† Values from Hurd and Bauer (ref 4) for polytryptophan, the average molecular weight of which is 4,000

Although there are no significant differences between the absorption properties of acetyl- and poly-tryptophan, tryptophan–tryptophan interactions may be detected more readily by the fluorescence properties of the aromatic amino-acid side-chain Emission intensities in the 3400 Å region were measured for solutions having optical densities of 0 050–0 250 at the absorption maximum In all solvents, the polymer was consistently 35–45 per cent less fluorescent than either acetyltryptophan or tryptophan ethyl ester in the same solvent. The decreased fluorescence of the polymer may be a reflexion of quenching as a consequence of the high local concentration of the aromatic groups.

The absence of hypo- or hyper-chromic effects in the absorption of polytryptophan suggests that either the transition moments of the freely rotating aromatic side-chains are not oriented or interactions between identical transitions cannot be detected by absorption studies The present work also indicates that the high quantum yield of some tryptophan-containing proteins is not explicable in terms of tryptophan stacking as has been suggested[6] Borrowing from or lending energy to other groups in the protein may account for unusual fluorescent properties of some albumins as recently reported by Weber[7]

Absence of Correlation between Odour and Molecular Vibration

IN 1928 Dyson[1] proposed a relationship between odour and molecular vibration This hypothesis was worked out in more detail by Wright[2–6], who correlated the odour of a compound with its low-frequency vibrations (below 800 cm $^{-1}$)

Wright postulates that odour-perception is caused by the interaction between the odorous molecule and a pigment molecule present in the olfactory cell. The former is attached to the latter by "forces of adsorption, or something of the sort"[5] The pigment molecule is permanently in an excited electronic state and can only fall back to its electronic ground-state if the relevant selection rule is relaxed by a perturbation due to the odorous molecule in "a process akin to Fermi-resonance"[6]. This perturbation is thus assumed to occur only if the odorous molecule and the receptor molecule have one or more identical vibration frequencies The electronic transition then triggers an electrical process in the cell membrane Leaving the electronic transition and its selection rules out of discussion in this communication, we will now examine the vibrational interactions more closely

It is easily seen that no correlation can be found between the vibrations of a free molecule and its odour if the molecule forms a complex with the receptor molecule, as the vibrational frequencies of the complex are never the same as those of the constituent parts As a consequence any molecule attached to the pigment molecule would give rise to odour-perception if the mechanism proposed by Wright applies

A second possibility exists in very weak interactions, which, for example, give rise to coupling of vibrations of molecules in crystals As the perturbation is weak, it is very questionable, however, whether it can change the selection rule for the electronic transition The strongest objection to this vibrational coupling lies in the odours of hydrogen sulphide and deuterium sulphide There are no grounds to believe that these compounds behave differently from all other substances From the fact that the vibrational (and also rotational) frequencies of hydrogen sulphide and deuterium sulphide are completely different, it follows that there should be a distinct difference between the odours of these two compounds

In an experiment similar to that described by Wright as inconclusive, the odours of hydrogen sulphide, deuterium oxide and deuterium sulphide were compared The fundamental frequencies[7] of hydrogen sulphide, deuterium oxide and deuterium sulphide are listed in Table 1 As an influence of molecular rotations cannot be excluded, the rotational constants[8,9] are also given

Table 1 THE FUNDAMENTAL FREQUENCIES AND ROTATIONAL CONSTANTS IN CM^{-1} OF DEUTERIUM SULPHIDE (D_2S), DEUTERIUM OXIDE (D_2O) AND HYDROGEN SULPHIDE (H_2S)

	D_2S	D_2O	H_2S
ν_2	934	1 179	1,290
ν_1	1,892	2,666	2,611
ν_3	1 999	2,789	2,684
A	5 47	15 38	10 39
B	4 49	7 25	9 04
C	2 44	4 83	4 72

Judged from the vibrational frequencies, the odours of hydrogen sulphide and deuterium sulphide should be quite different, deuterium oxide should have an odour falling between that of hydrogen sulphide and deuterium sulphide The rotational constants also indicate that the odours of hydrogen sulphide and deuterium sulphide would be different if molecular rotations play a part.

The odour of deuterium sulphide was tested in the following way Deuterium sulphide was synthesized by adding anhydrous aluminium chloride to a solution of sodium sulphide in pure deuterium oxide The trace of gas (the smell of which was near the threshold of detection) was kept in a stoppered bottle which was opened only long enough for each person to recognize the odour. As the deuterium in deuterium sulphide exchanges very rapidly, especially when in contact with the mucous membrane of the nose, this membrane was thoroughly 'deuterated' immediately before each experiment by spraying deuterium oxide into the nose, especially in the region of the olfactory epithelium Recognition of the odour of *p*-dichlorobenzene before and after deuteration showed that this treatment does not affect the observer's sense of smell. The four observers all agreed on the following

(1) Deuterium oxide is odourless (2) Deuterium sulphide cannot be distinguished from hydrogen sulphide (3) The intensity of the smell of deuterium sulphide is independent of the precautions taken to ensure that no hydrogen–deuterium exchange takes place This proves that the actual odour of deuterium sulphide was smelt and not that of traces of hydrogen sulphide which may have been present

This experiment thus seems to indicate that odour-perception is not linked with the vibrations of the free molecules

If relaxation of the selection rules for an electronic transition is assumed to trigger the nerve impulse, it is very plausible that the formation of a weak complex with the accompanying redistribution of charge in the participating substances is the first step in the process of odour-perception It is clear that there are other less-complicated processes, such as induction effects, which are able to trigger nerve impulses after complex-formation Unfortunately little is known at present about the pigment molecules in the olfactory cells. It seems fruitful, however, to investigate the possibility of correlations between odour and molecular properties such as electron distribution.

Large-Scale Polymer Column Fractionation

THE gradient elution method for polymer fractionation was introduced by Williams[1-3] To fractionate larger amounts of polymer, a scaled-up apparatus was necessary Previous experience in column design in this laboratory advised against an increase in the dimensions of a single column to avoid difficulties in temperature control and channelling. Consequently, an apparatus was built with six parallel columns, each 1 m in length and 2 5 cm in inside diameter A sketch of the multicolumn unit is shown in Fig 1 The upper ends of the aluminium columns are welded to the bottom of a common solvent-mixing container The metal container is 7 litres in capacity and is fitted with a heater, regulator, stirrer, and sight glass The solvent mixture is heated to the proper temperature for the desired column temperature gradient The lower ends of the columns are connected to a common outlet and immersed in a water thermostat The temperature gradient along the insulated columns is found to be nearly linear, as measured by four evenly spaced thermocouples The apparatus is charged and operated similarly to single columns previously described[1-3] Two ganged 'Minipumps' (Milton Roy Company, Philadelphia, Pennsylvania), each with an adjustable 12–120 ml /hr pumping capacity, regulate the rate of withdrawal of polymer solution from the common outlet The pumps also replenish the solvent at the head of the column at the same rate, thus establishing the solvent gradient and degree of fractionation The evaporation of the solvent for recovery of fractions is done automatically, *in situ*, using a rotary vacuum evaporator, fitted with a nitrogen inlet, vacuum line, and water-bath. A low evaporation temperature coupled with the nitrogen ensures polymer stability

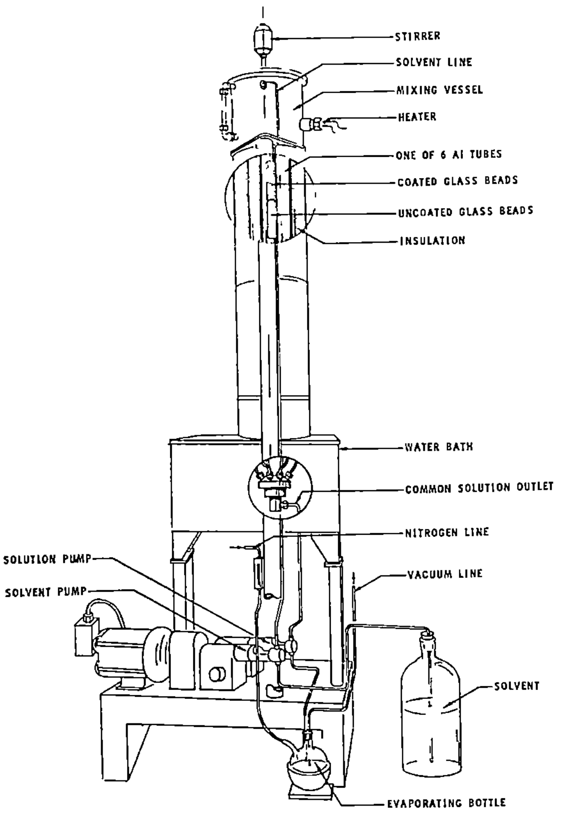

Fig 1. Multi-column unit

As an example of apparatus performance, Table 1 gives results on the fractionation of 34 gm. of 'Vistanex *LM–MS*', a commercial polyisobutylene The columns were packed with glass beads, average diameter 0 1 mm The non-solvent employed was acetone, the solvent benzene The temperature decrease down the column was from 50° to 28° C At a throughput of 80 ml /hr , the fractionation required eight days Polymer recovery was 95 per cent The molecular weights were determined by viscosity measurements in carbon tetrachloride at 30° C and evaluated according to the relation given by Fox and Flory[4] Table 1 shows good fractionation in light of the low degree of original inhomogeneity. for the unfractionated polymer, $M_w/M_n = 2\ 6$ As the apparatus requires little attention after starting up, fractionations require appreciably less effort than conventional precipitation methods and no more time than single-column operation Successful fractionations have been made with sample sizes of 30–50 gm , depending on polymer molecular weight and type

Table 1 Large-scale Fractionation Data for Polyisobutylene

BIOCHEMISTRY

Determination of the Biological Availability of Methionine and Cystine

There is no adequate method to determine the biological availability of the sulphur-containing amino-acids in the chick, but Schweigert and Guthneck[1] have described a technique for the rat A method has therefore been developed for the bio-assay of methionine using White Leghorn chicks at 11–18 days of age it can readily be modified to determine methionine plus cystine in terms of methionine equivalence By difference an indication can be obtained of available cystine The basal ration contains (per cent) 48 6 maize starch, 35 extracted soybean meal, 5 dried whey, 5 beef tallow, 6 mineral and vitamin mixture[2], 0 2 choline chloride and 0 2 glycine All supplements to this ration replace part of the maize starch Where test materials are calculated to contribute less 'metabolizable' energy than starch additional tallow is included to correct for the difference

It was first established that methionine was the only amino-acid limiting growth and food utilization This was accomplished by supplementing the diet with all other amino-acids singly and in various groups all in the presence of sufficient methionine to correct the known deficiency In no case was any growth improvement observed, but it was shown that part of the methionine deficiency could be satisfied by L-cystine A standard supplement of 0 4 per cent L-cystine was therefore included in all diets to eliminate the effect of any cystine in test proteins When the methionine deficiency was corrected, chick growth was limited only by the protein-level of the diet A relatively low protein-level was chosen since this tends to maximize the response to methionine supplements when these are expressed as a proportion of the protein

In the presence of excess L-cystine the growth response to additions of methionine is essentially linear on a logarithmic dose basis within the range of 0 01–0 1 per cent of the diet. Similarly, in the absence of added cystine the linear range is approximately 0 04–0 2 per cent (Fig 1) These are the potential ranges for the bio-assay of methionine and methionine plus cystine respectively.

In order to satisfy the requirements for a bio-assay procedure it has been established that chick growth is a function only of the methionine or cystine content, that a constant growth response is obtained on repeated assay and that a linear and parallel response is obtained on the inclusion of graded amounts of standard and test materials in the diet Using this technique, assays of biologically available methionine and cystine have been made on several

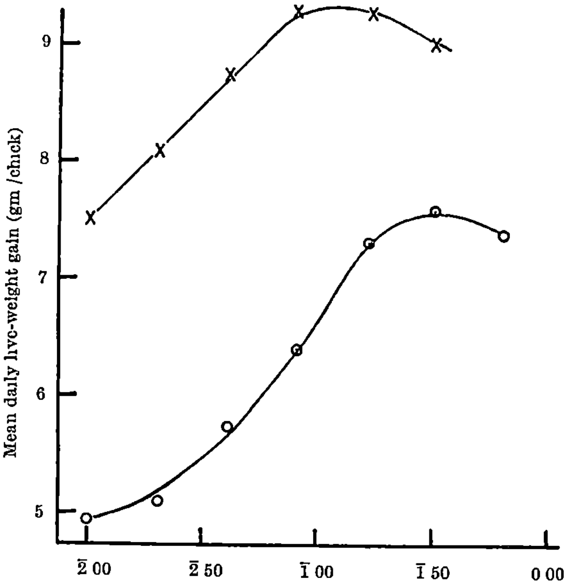

Fig. 1. Growth response of male White Leghorn chicks to graded supplements of DL-methionine. O, DL-methionine; ×, DL-methionine plus 0.4 per cent L-cystine

soybean samples (Table 1). The second experiment quoted refers to three extracted soybean meals obtained from the samples examined for protein quality in animal feeding-stuffs by the Agricultural Research Council. The values for both available methionine and cystine are uniformly high in relation to chemical determinations. These samples had received varying heat treatments but none was shown to exhibit more than slight urease activity. On the other hand, a somewhat lower availability of these amino-acids was found in C-1 assay protein. This agrees with the observations of Turk *et al.*[3] and Ousterhout *et al.*[4] and also with our preliminary results, which suggest low availability of cystine in 'underheated' soybean meal samples (high urease activity).

Table 1. ASSAYS OF AVAILABLE METHIONINE AND METHIONINE PLUS CYSTINE (BASED ON LIVE-WEIGHT DATA)

In all cases cystine is expressed as methionine equivalence. Chemical determinations by a Moore and Stein technique. The fiducial limits are quoted at 5 per cent level of probability. All values expressed as gm./16 gm. nitrogen

	Methionine Assay	Methionine Fiducial limits	Methionine + cystine Assay	Methionine + cystine Fiducial limits	Cystine (by difference)
Experiment 1					
C-1 assay protein (soybean, 14.1% N)	0.97	1.22 0.74	1.68	2.14 1.36	0.71
Chemically determined	1.39		—		1.02
Availability (per cent)	70		—		69
Experiment 2					
Soybean 22 (8.01% N)	1.61	2.11 1.23	3.30	4.27 2.62	1.69
Soybean 23 (8.24% N)	1.74	2.30 1.33	3.16	4.08 2.51	1.42
Soybean 24 (7.81% N)	1.44	1.89 1.09	2.97	3.81 2.36	1.53
Mean of three samples	1.60		3.14		1.54
Chemically determined	1.78		—		1.80
Availability (per cent)	90		—		86

Table 2. EFFECTS OF L-GLUTAMIC ACID AND AN AMINO-ACID MIXTURE ON THE RESPONSE TO GRADED SUPPLEMENTS OF DL-METHIONINE

Amino-acids added so that the total nitrogen is approximately equal to that of test proteins. Fiducial limits at 5 per cent probability

	Relative potency* per unit DL-methionine: In presence of 0.4 per cent L-cystine	Fiducial limits	In absence of cystine	Fiducial limits
Methionine + L-glutamic acid	0.98	1.23 0.78	0.92	1.12 0.75
Methionine + amino-acid mixture	0.92	1.16 0.74	1.01	1.23 0.83

* Computed according to Finney (ref. 6).

In view of the observations of Fisher *et al.*[5] it was considered necessary to examine the possible effect of additional amino-acid inclusion on the response to standard supplements (Table 2). Neither supplements of L-glutamic acid nor a complete amino-acid mixture[5] significantly modified the growth pattern. This shows that under the conditions of this experiment alteration of amino-nitrogen or essential amino-acid status did not alter the response to methionine supplements.

Thanks are due to the Agricultural Research Council for financial support and to J. G. Rowell, Agricultural Research Council Statistics Group, Cambridge, for assistance with statistical computations.

Cation Toxicity and the Stability of Transition-Metal Complexes

DESPITE the many important contributions that have been made to the literature during the past century, no completely satisfactory theory of cation toxicity has been formulated. Blake[1] first concluded that there was a correlation between degree of toxicity and atomic weight (hence 'heavy-metal' poisons). Matthews[2] and Jones[3] later pointed out a relationship between metal ion toxicity and the 'solution pressure' (standard electrode potential) of the corresponding metals. Seifriz[4] considered various other chemical properties of the ions in his attempt to find a satisfactory chemical explanation for the relative toxicity of cations. Shaw[5-7], basing his arguments on results obtained with enzymes, postulated that metal ions killed aquatic organisms by combining with an essential group (probably —SH) on a key enzyme. Correlation with metal sulphide insolubility was demonstrated. An attempt was also made[6] to relate the relative inhibitory efficiency of bivalent metal ions toward the enzyme urease with metal complex stability. At that time (early 1953), however, the field of co-ordination chemistry had not reached a stage of sufficient maturity for such a comparison to be successfully made. The explosive growth that has occurred during the past decade in our knowledge of the chemistry of co-ordination compounds necessitates a re-examination of the intriguing possibility that there exists a relationship between metal complex stability and the toxicity of metal ions to living organisms.

In their classic paper, Irving and Williams[8] collected and critically examined available data on

Table 1 TOXICITY OF TRANSITION-METAL IONS

Organism or enzyme	Ref	Toxicity* of Mn(II)	Fe(II)	Co(II)	Ni(II)	Cu(II)	Zn(II)
Daphnia magna	14	3.4	4.0	4.6	5.3	6.8	6.0
Urease	12	2.5	4.1$_9$	4.2$_3$	4.5	6.5	5.7
Stickleback	15	3.1	—	3.8	4.9	6.6	5.3
Guppy	7	2.2	—	3.3	4.7	6.5	5.7
Tadpole	7	2.1	—	4.0	4.1	6.5	5.0
Polycelis nigra	3	1.9	—	2.8	3.1	5.2	3.3
Diastase	16	0.79	—	2.0	3.0	3.9	1.8
Paramecium	17	1.0	—	1.2	1.2$_{[illegible]}$	2.7	0.90
Fundulus eggs	2	0.30	1.0	1.1	1.2	4.2	0.60

* Toxicities are reported on a *pI** scale (refs 5–7) that is, as the negative logarithm of the reported metal-ion concentration necessary to produce the particular level of biological response (LD_{50}, etc) arbitrarily established by the researcher *pI* values for enzymes have been discussed elsewhere (refs 5 and 12)

the stability of complexes formed by bivalent ions of the first transition series The Irving–Williams or 'natural' order. Mn(II) < Fe(II) < Co(II) < Ni(II) < Cu(II) > Zn(II) was found to hold for the stability of nearly all complexes irrespective of the nature of the ligand Theoretical justification for this important finding has been presented[8-10] The relevance of the Irving–Williams order to biological processes in general has been eloquently emphasized by Williams[10,11] Most of the examples used by him to illustrate his thesis were based on work on enzymes requiring metal ions and on metal-ion-catalysed reactions of model systems Work on the applicability of the Irving–Williams order to the inhibition of enzymes by metal ions are not numerous, but recent work[12] has demonstrated that metal ions in the absence of phosphate buffer inhibit urease in the order Mn(II) < Fe(II) < Co(II) < Ni(II) < Cu(II) > Zn(II) Since it seems reasonable to assume[6,7,13] that metal ions are toxic to living organisms because they combine with some ligand (probably itself part of an enzyme) necessary for life, one might naïvely expect the toxicity of transition-metal ions to follow a sequence similar to the Irving–Williams order. A more sophisticated view, however, would lead one to expect that complications involving competition of the host of ligands present in living systems for the metal ions might completely obscure such a simple relation[11]. This sophisticated view does not seem to be correct (Table 1), and the amazing fact is that all the data obtained throughout the years from the many different laboratories where work on the toxicity of metal ions to aquatic organisms has been done follows the toxicity sequence Mn(II) < Fe(II) < Co(II) < Ni(II) < Cu(II) > Zn(II) The relationship holds also for urease, diastase, and other enzymes (Table 1) In media containing concentrated phosphate or other ligands with strong affinity for metal ions the sequence may, of course, be broken

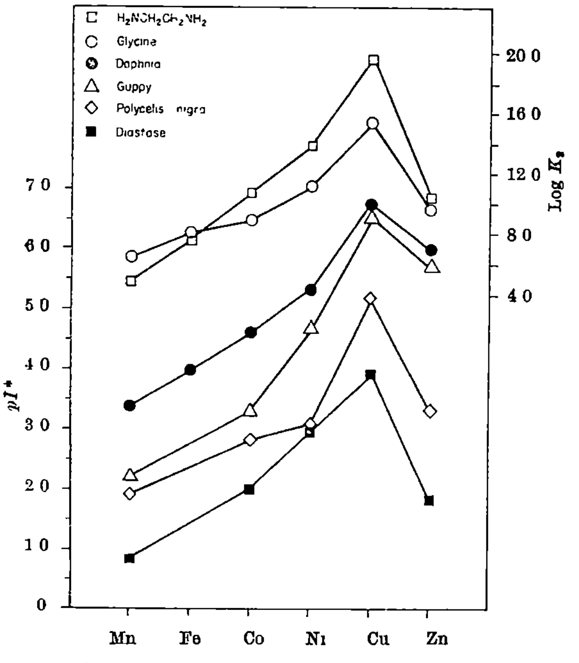

Fig 1 Correlation of transition-metal complex stability (ref 11) (two upper curves, right ordinate) with transition-metal ion toxicity (lower curves, left ordinate) Toxicities in *pI** units were obtained from Table 1

A comparison of toxicity with complex stability[11] is shown in Fig 1

The results of this investigation (Table 1, Fig. 1) establish the toxicity sequence proposed by me Mn(II) < Fe(II) < Co(II) < Ni(II) < Cu(II) > Zn(II) as one that is of very general significance in aquatic biology and one that is also firmly based on the principles of co-ordination chemistry

A Simplified Culture Medium for the Production of Collagenase

PRESENT methods for the production of *Clostridium histolyticum* collagenase depend chiefly on growth of the organism in complex culture media[1,2] It is the purpose of this communication to describe a relatively simple, partially defined medium for the production of large quantities of highly active fermentation broths of *Cl. histolyticum* collagenase The medium described appeared to facilitate the isolation and purification of collagenases which were essentially free of non-specific proteinases[3]

The organism used in these experiments was *Cl histolyticum* 47Q–5 obtained from the Army Medical Service Graduate School, Washington, D C A metabolically constant source of collagenase was prepared by pre-treating the organism in the following manner A 24-hr. culture was injected intragluteally into Swiss mice through five serial passages Isolation (muscle exudate) was accomplished and growth continued in a seed medium of composition casein hydrolysate, enzymatic (General Biochemicals, Chagrin Falls, Ohio), 16 gm , sodium succinate 5 gm , sodium pantothenate, 0.1 mgm ; pyridoxamine, 0·2 mgm.; nicotinamide, 0·8 mgm., uracil, 1·5 mgm., riboflavin, 10 μgm., biotin, 0·1 μgm., vitamin B_{12}, 63·0 μgm., and distilled water to 1,000 ml. (*p*H 7·6). Stock cultures of *Cl. histolyticum* were maintained in 'Pyrex' tubes (25 × 200 mm.) containing 40 ml. of this medium to which 1 gm. of dry, fat-free bovine heart was added. The stock cultures were transferred at monthly intervals and were refrigerated in the interim. The culture medium used in the production of collagenase consisted of the following constituents in 1 l. of medium. Solution 1, casein hydrolysate (enzymatic), 40 gm., sodium succinate, 1·25 gm.; sodium thioglycollate, 1·0 gm., $Na_2HPO_4.12H_2O$, 5·8 gm., KH_2PO_4, 0·48 gm., gelatin, 2·0 gm. Solution 2 (stock vitamin preparation), calcium pantothenate, 1·0 mgm., pyridoxamine, 2·0 mgm.; riboflavin, 0·1 mgm., nicotinamide, 8·0 mgm., uracil, 15·0 mgm., biotin, 10·0 μgm., vitamin B_{12}, 63·0 μgm. Solution 3, dextrose (50 per cent), 5·0 ml. After preparation of solution 1, the incomplete medium was adjusted to *p*H 7·6 with 5 *N* sodium hydroxide. Solution 2 was then added and the combined medium was then placed in an autoclave for 15 min. at 15 lb./sq. in. After cooling, Seitz-filtered glucose (solution 3) was added aseptically. 9-l. 'Pyrex' carboys containing 6·5 l. of medium were used. The inoculum was prepared in 500 ml. of broth of the same composition as that being used to produce collagenase. The maximum yield of enzyme was obtained after 48 hr. incubation at 24–25° C. The bacterial cells were removed by filtration through 'Hyflo Super Cel' and the *p*H of the filtered broth adjusted to 7·5–7·6 with 5 *N* sodium hydroxide. Collagenase activity was measured by hydrolysis of undenatured Achilles tendon collagen as described in ref. 3. One collagenase unit was defined as the amount of activity catalysing the solubilization of 1 mgm. of 40–60 mesh collagen under standard conditions. It was found that the foregoing relatively simple procedure provided broths with collagenase activity that averaged 107 units of enzyme a ml. The average yield of purified preparations of collagenase expressed as collagenase *A* was 140 mgm./l. of fermentation beer.

Crystallization of Deuterated Ribonuclease

WE have prepared deuterated bovine pancreatic ribonuclease (Armour, lot 381–059) by the procedures of Hermans and Scheraga[1]. Both RNaseH_{20} (all but 20 exchangeable H's exchanged) and RNase all-deuterated crystallized from 55 per cent (v/v) aqueous 2-methyl-2,4-pentanediol (deuterated solvent) in form II[2]. The intensities of the X-ray reflexions along the principal axes were identical within experimental precision to those of non-deuterated crystals out to $2\theta = 60°$ (1·5 Å resolution), at higher angles RNase gives poor reflexions. The lattice constants were identical to those of undeuterated crystals within the normal variation (± 0·05 Å and ± 0·03°). The small differences between deuterium bonds and hydrogen bonds do not change the structure of RNase within the limits observable by X-ray diffraction. Detectable changes might be produced in the case of a crystallizable protein with a transition temperature near room temperature instead of the high transition temperature (61° C.) of RNase[3].

The deuterated crystals were prepared by Miss Sylvia Scapa and Mrs. H. R. Bello; diffraction patterns were taken by Miss E. De Jarnette.

Properties of Xanthine Dehydrogenase in the Silkworm, *Bombyx mori* L.

THE enzyme which catalyses the oxidation of purine derivatives xanthine and hypoxanthine to uric acid has been demonstrated in several insects[1–5]. In the silkworm, *Bombyx mori*, it functions as a dehydrogenase. This inference is based on the fact that the formation of uric acid and oxygen consumption of the fat body homogenates show marked increases only when methylene blue is present as a hydrogen carrier[6,7]. The inference seems to be justifiable from the work of Remy *et al.*[8] using chicken liver. To gain further knowledge of the nature of xanthine dehydrogenase in the silkworm, it will be desirable to use the highly purified enzyme as in milk[9,10] and liver[11] oxidase preparations.

The present report deals with preliminary work on the properties of the xanthine dehydrogenase in the silkworm. The enzyme was prepared from the fat body according to the methods of Kielley with a few modifications (Hayashi, unpublished). The enzyme activity was determined from oxygen consumption and uric acid formation by a method similar to that described in the previous paper using crude tissue homogenates of silkworm larvæ, with methylene blue as a hydrogen carrier between xanthine dehydrogenase and molecular oxygen[7].

Purified preparations of the silkworm enzyme are yellowish-brown in colour. The enzyme has two absorption bands with maxima at 360 and 405–410 mμ, the latter disappearing when reduced by hydrosulphite. The absorption spectrum of the silkworm enzyme is similar to that of the chicken liver enzyme[8] and aldehyde oxidase[12]. The difference spectrum was not conspicuously characteristic of flavin and is probably a compound of flavin plus an unknown group.

In recent work it has been reported that xanthine oxidative enzyme from some animal tissues contains iron, molybdenum and flavin as the prosthetic groups. The mammalian liver xanthine oxidase of Kielley[11] has an Fe : Mo : flavin ratio of 4 : 1 : 1 and the chicken liver xanthine dehydrogenase of Remy *et al.*[8] has a ratio of 8 : 1 : 1. From the purified preparation of xanthine dehydrogenase from silkworm fat body, it was determined that the ratio is 9 : 1 : 1, thereby showing closer resemblance to the latter rather than the former prosthetic group.

Milk[10] and chicken liver[8] enzyme are capable of oxidizing a number of oxypurines and aldehydes as well as reduced diphosphopyridine nucleotide (DPNH), but slowly with pterines. The silkworm xanthine dehydrogenase oxidized xanthine, hypoxanthine, guanine, adenine, aldehydes, 2-amino-4-hydroxypteridine and xanthopterin, while the oxidation of DPNH by the enzyme proceeded faster only when cytochrome *c* was added as an electron acceptor. In these substrates 2-amino-4-hydroxypteridine and xanthopterin were oxidized faster than the purines such as hypoxanthine and xanthine.

A wide variety of electron acceptors has been used in the enzyme system. Methylene blue, tetrazolium salts, indophenol, diphosphopyridine nucleotide (DPN), cytochrome *c*, flavin adenine dinucleotide (FAD), and sodium pyruvate have been shown to be acceptors. The enzyme activity of the reaction systems mentioned showed its maximum rate with methylene blue; DPN and FAD showed the same rate.

The activity of the silkworm enzyme has a wide *p*H range of 6–11 with a maximum velocity at *p*H 8·4. A number of substances have been found to be possible inhibitors of silkworm enzyme. Among them the more effective inhibitors are potassium cyanide and *o*-iodobenzoic acid, whereas xanthine oxidase inhibitors such as ascorbic acid, *p*-aminophenol, hydroxylamine, quinine, and antimycin *A* were not recognized as inhibitors.

As shown from the results stated above, the property of the xanthine enzyme system in silkworm fat body is not similar to that of mammalian liver enzyme but bears a striking likeness to chicken liver enzyme except in the case of substrate specificity. From this, it is inferred that the properties of xanthine oxidative enzymes vary from source to source.

I thank Prof. K. Hasegawa and Dr. K. Muramatsu for valuable advice and help throughout this work.

Conversion of 2-^{14}C-Pteroyl-L-Monoglutamic Acid into Isoxanthopterin in *Drosophila melanogaster*

2-^{14}C-Pteroyl-L-monoglutamic acid (0·5 mc. per millimole, 1 mgm.) was incorporated into banana food medium (100 gm.), and adult flies of *Drosophila melanogaster* (Oregon, wild-type) were allowed to feed and lay eggs on this medium. Larvæ (six days old) were removed from this medium, transferred to moist filter paper and allowed to pupate. Pupæ (100; 86 mgm.; not less than 48 hr., not more than 56 hr. pupation) were crushed with sand and 0·5 *N* aqueous ammonia solution (0·5 ml.) and heated on a steam-bath (10 min.). Solids were centrifuged off and supernatant liquid spotted on Whatman 3 *MM* paper. The solids were washed again with 0·5 *N* aqueous ammonia solution (0·4 ml.), centrifuged off and supernatant liquid added to the first spot. The paper area was cut out and radioactivity measured by immersion in a solution of 0·3 per cent diphenyloxazole in toluene (2 ml.) and counting with a 'Panax' scintillation counter (background, 1·096 counts/sec.; background + sample, 1·357 counts/sec.; sample, 0·26 count/sec.; standard error, ± 0·035 count/sec.). The radioactive area of the paper was chromatographed on 3 *MM* paper with propanol/5 per cent aqueous acetic acid (2 : 1 vol. by vol.) as developing solvent. To improve spot resolution, the paper was developed three times. On viewing in 365-mμ light, a bright purple fluorescent area was seen. This was cut out and chromatographed on 3 *MM* paper with butanol/acetic acid/water (4 : 1 : 5 vol. by vol.) (triple development). After air-drying, the paper was viewed in 365 mμ light and the fluorescent spots of isoxanthopterin (purple) and 2-amino-4-hydroxypteridine-6-carboxylic acid (bright blue) cut out. The acid spot was measured for radioactivity (background, 0·65 count/sec.; background + sample, 1·10 counts/sec.; sample, 0·45 count/sec.; standard error, 0·033 count/sec.). The isoxanthopterin spot was further purified by chromatography on 3 *MM* paper with *tert.*-butanol/pyridine/water (50 : 15 : 35 vol. by vol.). The isoxanthopterin spot was measured for radioactivity (background, 0·65 count/sec.; background + sample, 0·76 count/sec.; sample, 0·11 count/sec.: standard error, 0·030 count/sec.).

The counting efficiencies of the isoxanthopterin spot and the original paper area (after development) were measured by adding known weights of 2-^{14}C-pteroyl-L-monoglutamic acid and determining the radioactivity of the paper areas. The counting efficiency of the isoxanthopterin spot was about 12·1 per cent and that of the original paper area about 6·7 per cent. The isoxanthopterin therefore represented about 20 per cent of the radioactivity present in the sample, the remainder being accounted for by the 2-amino-4-hydroxypteridine-6-carboxylic acid.

The pterin isoxanthopterin is widely distributed in Nature. It has been suggested that it is the end-product of the catabolism of folic acid (pteroyl-L-monoglutamic acid), being formed by the following steps[1,2]:

$$\text{pteroyl-L-monoglutamic acid} \xrightarrow[\text{(2) hydrolysis}]{\text{(1) dehydrogenation}}$$

$$\text{2-amino-4-hydroxypteridine-6-aldehyde} \xrightarrow[\text{oxidase}]{\text{xanthine}}$$

$$\text{2-amino-4-hydroxypteridine-6-carboxylic acid}$$

$$\xrightarrow{\text{decarboxylation}} \text{2-amino-4-hydroxypteridine}$$

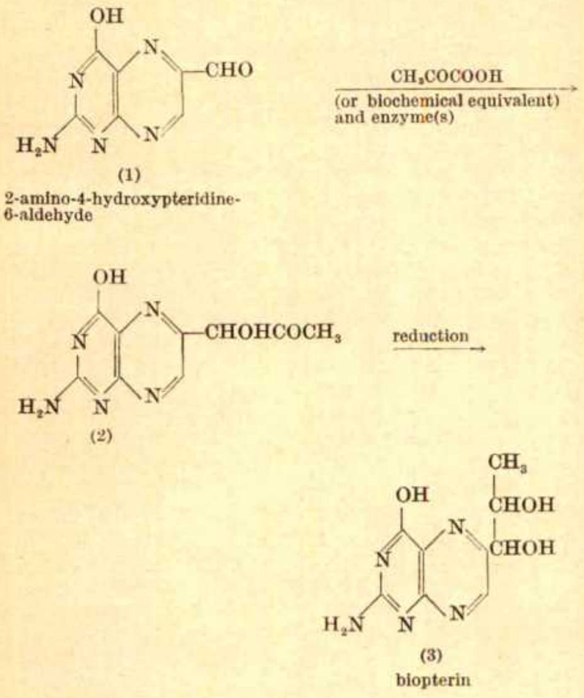
$$\xrightarrow[\text{oxidase}]{\text{xanthine}} \text{isoxanthopterin}$$

Isoxanthopterin can be readily isolated from the pupæ of *D. melanogaster*, and it has been shown that 6,7-^{14}C-2-amino-4-hydroxypteridine is converted only into radioactive isoxanthopterin in pupæ[3]. Work with mutants of *D. melanogaster*, which do not produce isoxanthopterin but instead accumulate large amounts of 2-amino-4-hydroxypteridine and biopterin, shows that this failure to produce isoxanthopterin is due to deficiency of the enzyme xanthine oxidase[3].

D. melanogaster larvæ and pupæ can synthesize folic acid in limited amount but require to be supplied with folic acid for their normal growth[4].

The experimental results establish that some of this supplied folic acid is converted into isoxanthopterin by the pupæ.

D. melanogaster mutants that do not form isoxanthopterin accumulate 2-amino-4-hydroxypteridine and biopterin. The latter is not formed from the former[3]. If the biogenetic scheme suggested is correct, then if xanthine oxidase is lacking, large amounts of 2-amino-4-hydroxypteridine-6-aldehyde should be formed. This could be converted to biopterin by the following steps:



OH
N
N
CHO
H₂N
N
N
(1)
2-amino-4-hydroxypteridine-6-aldehyde
CH₃COCOOH
(or biochemical equivalent) and enzyme(s)
OH
CHOHCOCH₃
H₂N
(2)
reduction
CH₃
CHOH
CHOH
(3)
biopterin

Analogies for the first step have been recorded. The enzymatic condensation of pyruvic acid with acetaldehyde and propionaldehyde yields acetoin and methyl acetoin[5]. Ultra-violet irradiation of pyruvic acid and benzaldehyde gives benzacetoin[6]. Benzacetoin is formed from benzaldehyde in alcoholic fermentation[7].

In accord with this prediction, mutants of *D. melanogaster* lacking xanthine oxidase accumulate biopterin as well as 2-amino-4-hydroxypteridine.

I am grateful to Prof. F. Weygand for a gift of 2-^{14}C-pteroyl-L-monoglutamic acid, to Dr. A. H. Ward for assistance with the radioactivity measurements and to Dr. M. Hollingsworth for the *Drosophila* stock.

PHYSIOLOGY

Soluble Collagen in Bone

CONSIDERABLE efforts have been made, so far, to investigate the physico-chemical as well as the biochemical nature of soft tissue collagen such as skin and tendon, especially. In refs. 1–3 it is suggested that the soluble collagen is the precursor of collagen. However, only scanty information has been provided in regard to the important role of bone collagen in the formation of bone[4]. Trials in refs. 5 and 6 have not been successful in proving the existence of soluble collagen.

To clarify the mechanism of ossification, we carried out experiments on the extraction and refinement of bone collagen. The first problem of the extraction of bone collagen is to eliminate the bone mineral which occupies the major part of bone. Some attempts have been made to solve this problem and de-calcification by dilute acids has been found to be most suitable. We took special care to prevent a loss of soluble collagen, since it might be missed in the process of demineralization; this enabled us to prove that the soluble collagen was obtainable also from bone.

Cortical bone of fresh bovine femur was pulverized with dry ice to obtain 100–200 mesh powder after complete removal of attached soft tissues and de-fatting with ether, then freed from remaining soft tissues by flotation[7]. This sample was stored at − 20° C. As for de-calcification, bone powder thus prepared was suspended in 0·1 *N* hydrochloric acid and dialysed at 4° C. in cellulose tubing, average pore radius 24 Å. (Visking Co.), against a flow of 0·1 *N* hydro-

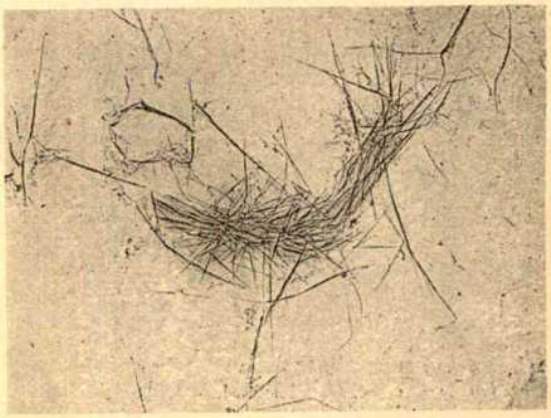

Fig. 1. Reconstituted fibres obtained from the soluble fraction of cortical bone (bovine femur) show a needle-like shape under the microscope. (× 300)

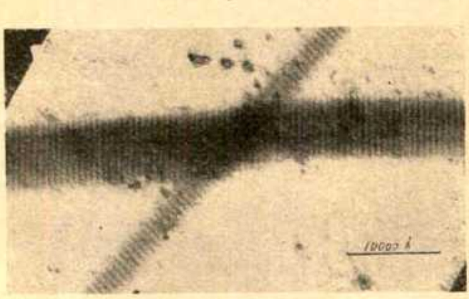

Fig. 2. Electron-micrograph of the reconstituted fibrils (*p*H 5·5, McIlvaine buffer) obtained from the soluble fraction of cortical bone (bovine femur). This shows the characteristic periods of 640 Å.; fixed with phosphotungstic acid, shadowed with palladium–platinum

chloric acid (10 l./day). After completion of demineralization (about 2 weeks), the non-dialysable portion of the extract in the tubes was separated from the residue by centrifugation (3,600g for 10 min.), sealed in the tubes and dialysed again at 4° C. by renewing the distilled water (10 l./day for 4 days).

Precipitate which appeared during dialysis was dissolved in McIlvaine buffer (7.1 vol. of 0.2 M sodium phosphate aq. : 12.9 vol. of 0.1 M citric acid aq., pH 3.8) after centrifugation (3,600g for 10 min.) and the supernatant was dialysed at 4° C. against McIlvaine buffer (11.6 vol. of 0.2 M sodium phosphate aq. : 8.4 vol. of 0.1 M citric acid aq., pH 5.5–5.6) containing 2 per cent sodium chloride followed by concentration with 50 per cent gum arabic.

A crystal of sodium chloride was added occasionally to promote the formation of fibre. As shown in Fig. 1, fibres showed a needle-shape under the microscope. They were rinsed with water repeatedly before fixation with 1 per cent phosphotungstate, washed again and suspended in water, then placed on grids and desiccated with calcium chloride. Thus, the electron-microscopical observation revealed the characteristic pattern of collagen with a 640-Å periodicity. This collagen fibre subjected to a repetition of this process gave the typical pattern of reconstituted collagen fibre with 640-Å periodicity (Fig. 2).

In addition, the amino-acid content of this reconstituted collagen was similar to that of so-called bone collagen, and it seems probable that the collagen fibre described is identical with collagen also from its contents of proline and glycine.

Flow of Blood in the Forearm of Persons acclimatized to Heat

IT is known, from experiments performed in climatic rooms in temperate countries, that the flow of blood in the forearm increases when people are exposed to heat, and that the magnitude of this increase diminishes progressively if the exposure to heat is repeated on successive days[1,2]. At the end of these experiments, however, the flow of blood in the forearm was always higher during the exposure to heat than it was before the experimental subjects were first exposed to heat. It cannot, therefore, be decided from these observations whether the flow of blood in the forearms of people who are fully acclimatized to heat, by long residence in a hot environment, are higher or lower than those of people who are not acclimatized to heat. An investigation into the flow of blood in the forearms of indigenous peoples of a hot, humid climate would provide information on the effects of long-term acclimatization to heat, but no measurements of blood-flow in tropical subjects appear to have been made until now.

In order to supply these data, the flow of blood in the forearms has been measured, by venous occlusion plethysmography in twenty-one male Asian subjects living in Singapore. The subjects were fifteen Chinese, four Indians and two Malays; their average age was 23.1 yr. (*S.D.* = ±3.8) and their mean body-weight was 57.7 kgm. (*S.D.* = ±7.9). All subjects had been born in Singapore, and they were therefore 'naturally' acclimatized to heat[3]. They were tested at the environmental temperatures of Singapore (mean dry-bulb temperature, 28.3 ± 1.1° C., mean wet-bulb temperature, 25.2 ± 0.7° C.) and they wore their normal clothing[4]. Each subject lay on his back for 90 min. before any measurements were made. Blood-flows were measured in four sets of five flows; each set lasted 2.5 min. and was separated from the next set of readings by a time interval of 15 min. The mean blood-flow for any one subject therefore represented the average of twenty flows taken over a period of approximately 1 hr.

The mean blood-flow in the forearms of the twenty-one subjects was 2.70 ml./100 ml. forearm/min., with a standard deviation of ±0.88 ml. There was some evidence that the flows of blood in the forearms of these subjects were not greatly altered by enclosure of the arm in a water-filled plethysmograph. Thus, during the hour in which blood-flows were measured, there were only random variations in the flow readings. Progressive cooling or warming of the forearm might have been expected to result in trends in the blood-flows over a period of 1 hr. The temperature of the water in the plethysmograph was 35.0° C.; the skin temperature of the forearm when it was in the plethysmograph must have been close to 35° C. In a similar group of subjects to that taking part in the present investigation, at a room temperature of 29.6° C., the mean skin temperature of the forearm when it was exposed to air was 34.88° C. (ref. 4). The skin temperature of the forearm while measurements of blood-flow were being made could not therefore have been very different from that before the arm was inserted into the plethysmograph.

From these considerations it seems reasonable to assume that the figure of 2.70 ml./100 ml./min. may be accepted as an estimate of the rate of blood-flow through the forearms of young men, at rest, in a hot, humid climate. This figure is of the same order of magnitude as flow-rates of 2.6–3.1 ml./100 ml./min., which have been reported for the clothed forearms of people at normal room temperatures (18.5°–20.0° C.) in England[5] and in North America[6]. The forearms of young men in Singapore are habitually bare; the skin temperatures of their forearms are, however, higher than those of the clothed forearms of people in England and North America[4]. For this reason, it might be expected that the flows of blood in the forearms of the subjects in Singapore would be greater than those of people in temperate countries. The experiments reported here have not provided any evidence to support this. It is possible that the relatively low values for blood-flow in the forearms of the Singapore subjects may be related to the fact that people acclimatized to heat in Singapore have low mean arterial blood pressures[7].

It is important to stress that these conclusions apply only to men who are at rest and who are not visibly sweating. Increased activity or the onset of sweating might result in a greatly increased bloodflow through the forearms of these subjects but evidence for this is, at present, lacking

New Indirect Fick Procedure for the Determination of Cardiac Output

THE indirect Fick method for determining cardiac output, which requires neither catheterization nor arterial puncture, would be the method of choice but for one serious drawback, namely, the difficulty of obtaining a reliable value for the carbon dioxide tension in (oxygenated) venous blood It is now generally recognized that, when the breath is held, no equilibrium between alveolar and mixed venous P_{CO_2} is attained in the 15–20 sec. before recirculation intervenes It has been proposed to plot the increase in pressure of alveolar carbon dioxide, P_{CO_2}, while the breath is held, and to compute the mean value of venous P_{CO_2} by means of extrapolation[1] Since alveolar P_{CO_2} cannot be measured while the breath is held, this method requires the determination of alveolar P_{CO_2} at the end of a number of successive periods of holding the breath of different lengths. This results in considerable scatter of the experimental points and, thus, in an appreciable degree of uncertainty regarding the value for alveolar P_{CO_2}

It was shown earlier[2] that, in the case of re-breathing in a bag initially filled with pure oxygen or with an oxygen – carbon dioxide mixture, the alveolar carbon dioxide tension after the *n*th breathing cycle, p_n, is given by an inhomogeneous linear second-order difference equation with constant coefficients

$$p_n = a + bp_{n-1} + cp_{n-2}$$

and that the second exponential, which is a function of the tidal volume/dead space ratio, becomes negligible after the first or second breathing cycle From then on, the process is a simple exponential one This means that, after the first few breaths, the p_n vs. p_{n-1} plot is a straight line

$$p_n = a + bp_{n-1}$$

or, if p_1 be the initial value of p

$$p_n = a(1 + b + b^2 - - - - - - b^{n-2}) + b^{n-1}p_1$$

The sum of the series in brackets being $(b^{n-1}-1)/(b-1)$, we have

$$p_n = \frac{ab^{n-1} - 1}{b - 1} + b^{n-1}p_1$$

For $n \rightarrow \infty$, a positive finite end value (p_∞) will be approached if $0 < b < 1$

This value is given by:

$$p_\infty = a\frac{0 - 1}{b - 1} = \frac{a}{1 - b}$$

Whether the asymptotic value is higher or lower than the initial value depends on the numerical values of a, b, and p_1

For p_2 to be higher than p_1 (also $p_3 > p_2$, etc.) we have

$$p_2 > p_1 \rightarrow a + bp_1 > p_1$$

or, since $bp_1 + (1-b)p_1 = p_1$, the condition can be written as:

$$a > p_1(1 - b)$$

Similarly, $p_n < p_{n-1}$ if $a < p_1(1-b)$

The first case corresponds to that in which the initial partial pressure of carbon dioxide in the bag is less than the true mean value of venous P_{CO_2}, and the second to that in which it exceeds this value The procedure is extremely simple At the end of a normal expiration, the subject is connected, by means of a three-way tap, to a 1-litre bag filled with an oxygen-rich oxygen–carbon dioxide mixture and re-breathes for a period not exceeding 15–16 sec At the end of each expiration, the concentration of carbon dioxide (per cent) in the bag is measured with the aid of a fast carbon dioxide analyser Scatter is minimized by having the subject re-breathe at a fixed tidal volume and at a fixed frequency (checked by metronome)

The p_n versus p_{n-1} plot is drawn, and if, after the first few points, a straight line is obtained, its slope and intercept of y (that is, b and a, respectively) are determined by the method of least squares, and p_∞ is calculated

Under certain conditions, such as unequal ventilation, etc, no straight line is obtained. In those cases the method is not applicable. The procedure is illustrated by Figs 1, 2 and 3. Fig 1 shows the record obtained with an infra-red analyser; the percentages of carbon dioxide after successive breathing cycles are plotted against time in Fig 2; the corresponding p_n versus p_{n-1} plot is shown in Fig 3 From the values for a and b (0 856 and 1·071 (760−47/100) = 7 636, respectively), p is found to be 52 30 mm mercury.

Values obtained with this method possess a high degree of reproducibility, as has been found in our laboratory and at the Lovelace Foundation Cardiac

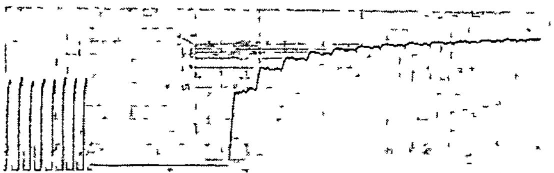

Fig 1 Record obtained from an infra-red analyser Concentration of carbon dioxide in bag at the end of successive expirations

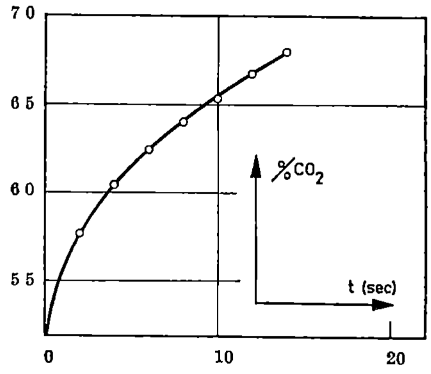

Fig 2

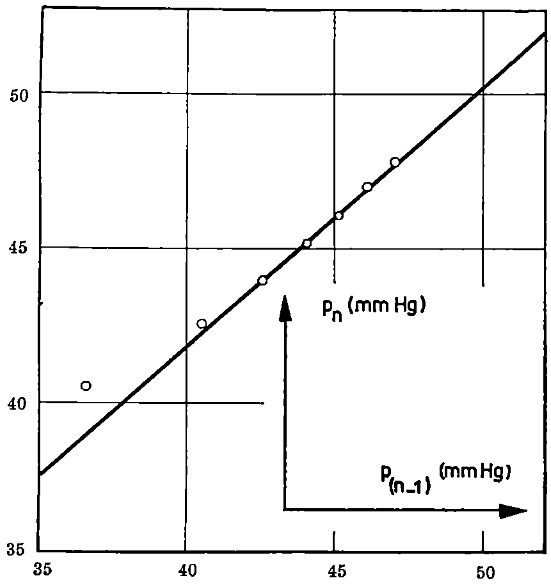

Fig 3

output values of resting normal subjects lie, as a rule, between 5 and 6 litres/min. At the time of writing, Dr. Mostyn (University of Alberta, Canada) is engaged in a series of experiments where the values for cardiac output obtained by the method described are compared with those found by the direct Fick method

A full report, including discussion of errors, will be published shortly in the *Acta physiol et pharmacol neerlandica*

Œstrus-inducing Activity of Testosterone in the Ewe

On the basis of results obtained with testosterone administered, together with pregnant mare serum gonadotrophin, to anœstrous ewes Cole[1] suggested that androgen may be responsible for the induction of œstrous behaviour in the sheep Robinson[2], however, has shown that œstrogen given following a period of progesterone priming will induce both behavioural and vaginal œstrus in spayed ewes, and it is probable that normal cyclic œstrous behaviour is due to an interaction of these two hormones In the course of work on the interaction of several steroid hormones on behavioural and vaginal œstrus in spayed ewes, a preliminary trial showed that a single dose of testosterone or of testosterone propionate resulted in mating behaviour in a number of animals Consequently, a factorial design test, using 72 spayed ewes, was conducted to examine this phenomenon and to define the nature of the apparent œstrous response The variables introduced (with $n = 12$) were priming treatment (no progesterone or 10 mgm per day for 12 days)[3], and dose of androgen (1 0, 3 2 or 10 0 mgm). The androgen was testosterone propionate Sexual receptivity of the ewes was determined using 8 intact rams fitted with 'Sire-sine' harnesses and crayons[4] and the vaginal response was determined by smears taken for four days following injection of androgen[5] Results are presented in Table 1.

Table 1 BEHAVIOURAL AND VAGINAL RESPONSE TO TESTOSTERONE PROPIONATE ADMINISTERED TO 72 EWES WITH OR WITHOUT PROGESTERONE PRETREATMENT

	Dose of testosterone propionate (mgm)	Treated with progesterone	Not treated with progesterone	Total
Behavioural response (n = 12)	1 0	6	4	10
	3 2	10	11	21
	10 0	12	12	24
	Total	28	27	55
Vaginal response (n = 12)	1 0	1	—	1
	3 2	1	1	2
	10 0	—	—	—
	Total	2	1	3

Full sexual receptivity was induced by testosterone propionate and the response appeared unaffected by previous administration of progesterone, and so differed markedly from that to œstrogen[3]. The dose response effect ($P < 0\ 001$) had the following form

$$y = 42\ 8\,x + 41\ 6$$

where $\sin^2 y$ = proportion of ewes responding, and $x = \log_{10}$ dose androgen, expressed as free testosterone (mgm). The median effective dose was 1 20 mgm , which suggests an œstrus-inducing activity comparable to that of œstriol[6]

Vaginal smears from only 3 ewes showed evidence of epithelial cornification and desquamation characteristic of œstrogen activity Only one of these ewes demonstrated behavioural œstrus, suggesting that these apparent responses were artefacts On the day of service, vaginal smears consisted of thin watery mucus with leucocytes and spermatozoa On the 3 succeeding days there was massive leucocytic invasion, and many smears consisted entirely of thin mucus and leucocytes with some cellular debris This is in marked contrast to the picture when behavioural œstrus is induced with œstrogen, where smears 2 and 3 days after service consist almost entirely of desquamated cornified cells, and leucocytes are almost absent[3,5]

The effect of testosterone in inducing behavioural œstrus in this test appears to have been one direct on the central nervous system It does not appear to have been a precursor for œstrogen, in which case the vaginal smears would have presented evidence of œstrogen activity It is well established that libido in women is due largely to androgen, presumably of adrenal origin[7], and the presence and production of androgens in ovarian tissue have been demonstrated[8] Cole, Hart and Miller[1] observed that some ewes treated with pregnant mare serum gonadotrophin and 100 mgm of testosterone exhibited homosexual activity The median effective dose of testosterone, as assessed from our test, is only about 1 per cent of the dose administered by these workers No abnormal behaviour was observed at our dose-rates

Œstrus has two distinct components—anatomical and psychic—and these can now be differentiated in the ewe Œstrogen, alone, commonly will induce vaginal œstrus without behavioural œstrus[3,5] Œstrogen, following a period of progesterone influence, will induce both vaginal and behavioural œstrus[2,3]. Testosterone will induce behavioural œstrus minus vaginal œstrus

Three conclusions may be drawn

(1) Œstrous behaviour may be attributed to direct action on the central nervous system of an appropriate hormone, and not to the conditioning of peripheral receptors in the uterus[2] or in the vagina

(2) The pattern of the behavioural response to gonadal hormone is determined by the sex of the recipient rather than by the nature of the hormone administered

(3) It is not suggested that androgens normally are responsible for cyclic œstrous behaviour in the sheep It is well established that œstrogen, in association with progesterone, has that role It is clear, however, that the terms 'œstrogenic' and 'androgenic', in their commonly accepted context, are largely meaningless when applied to behavioural responses

This project forms part of a programme on the physiology of reproduction in the sheep financed by the Australian Sheep and Wool Research Committee Testosterone propionate was kindly donated by G D. Searle and Co , Chicago, and progesterone by Fawns and McAllan Pty , Ltd , Melbourne

IMMUNOLOGY

Transfer of Immediate (Anaphylactic) Hypersensitivity by Homologous Bone Marrow or Spleen Cells

It has been repeatedly shown that lymph node cells from immunized donors transferred to irradiated recipients can transfer a specific antibody production and immunity state[1-3] We postulated that by implanting cells from a hyper-sensitized donor into a recipient made tolerant by whole-body irradiation, it would be possible to transfer the immediate type of hypersensitive state The present experiments demonstrate that the anaphylactic state can be obtained by transplantation of homologous bone marrow or spleen cells from sensitized donor guinea pigs into whole-body irradiated homologous recipients

Guinea pigs of a heterozygous randomly bred colony were used They were between 300 and 400 gm body-weight Donor animals were injected beneath the skin with 2 × 0·05 ml of horse serum emulsified in Freund's adjuvant mixture Six days later, bone marrow cells obtained from the femurs, tibiæ and humeri were suspended in cold Tyrode's solution The suspension of spleen cells was prepared by squeezing the mashed tissue through gauze; finally, cell suspensions were filtered through a loose cotton pellet In a group of sensitized animals injected intravenously six days later with 0·15 ml of horse serum no signs of anaphylactic reaction were observed (four animals) Animals challenged on the ninth day (two animals) manifested moderate symptoms, and on the fifteenth day three tested animals exhibited fatal anaphylactic reaction

In several experiments, previously irradiated animals and twenty-two unirradiated ones received cell suspensions intravenously Irradiated animals were exposed to 300, 400 or 700 r whole-body X-irradiation under the following conditions. 220 kV., 15 m amp , 0·5 mm of copper and 1 mm of aluminium, 40 cm from target to animal skin, 83 r / min According to the cells which they received the recipients were divided into three sub-groups The first obtained a mixture of about 11 × 10^7 viable nucleated bone marrow cells and 10 × 10^7 viable spleen cells The second sub-group received 11 × 10^7 bone marrow cells only and the third 10 × 10^7 spleen cells only Viability was estimated by the number of stained (dead) cells in a 0·2 per cent solution of eosin in Tyrode's solution. Cell suspensions were injected into the jugular vein within 3–5 hr after irradiation under light local anæsthesia (2 per cent novocain)

Nine days and in some cases 16 days after the cell transfer animals were challenged by intravenous injection of 0·15 ml horse serum (Not all the irradiated animals had survived up to that time) The ratio of the number of reacted to the number of tested animals as well as anaphylactic index for all experimental groups are shown in Table 1

As seen in Table 1, all the irradiated animals showed anaphylactic responses (in a few minutes after challenge). The degree and duration of the reaction were not the same in all animals but always pronounced, three animals died of shock. Only some of the unirradiated animals showed very weak symptoms which could be attributed to anaphylactic response

From these results it seems possible to conclude that:

(1) By injection of bone marrow or spleen cells it is possible to transfer the immediate type of hypersensitivity into recipient animals. The intensity of the

Table 1

Recipient animals group	Day of challenge (post-transfer)	Bone marrow + spleen cells		Bone marrow cells		Spleen cells		Total	
		Reacted to test	Anaphylactic index*	Reacted to test	Anaphylactic index*	Reacted to test	Anaphylactic index*	Reacted to test	Anaphylactic index*
Unirradiated	9	0/3	0	2/12	0·1	2/5	0·7	4/20	0·2
	16	0/2	0	—	—	—	—	0/2	0
300r	9	—	—	8/8	2·0	3/3	2·0	11/11	2·0
400r	9	6/6	2·8	4/4	3·0	6/6	3·5	16/16	3·1
	16	4/4	3·8	—	—	—	—	4/4	3·8
700r	9	4/4	3·8	5/5	2·4	2/2	2·0	11/11	2·7

* Anaphylactic index expresses the relative degree of anaphylactic state It is calculated by multiplying the number of animals showing fatal symptoms by 5, severe symptoms by 4, moderate symptoms by 3, mild symptoms by 2, very weak or uncertain symptoms by 1, without symptoms by 0, and dividing the sum of the products by the total number of animals challenged This is a slightly different system from that described in ref 5

anaphylactic response showed that the ability of spleen and bone marrow cells to induce anaphylactic response by transfer was about the same.

(2) Passive transfer of antibodies as a reason for reaction is not probable because (*a*) sensitized animals challenged on the sixth day did not show anaphylactic symptoms; (*b*) in this case unirradiated animals should have reacted also. This second reason seems to exclude direct antigenic stimuli of recipient animals if antigen were transferred together with cells from sensitized donor guinea pigs.

(3) The success of transfer seems to depend mainly on the possibility that the recipient animal rejects transferred cells. Failure to induce anaphylactic reaction is probably due to rejection of the sensitized cells before they can produce enough anti-horse serum antibodies. If the transferred cells have a better opportunity to colonize the recipient tissues and mature some days in them, the production of antibodies may be sufficient and an injection of horse serum can elicit an anaphylactic reaction. In this experiment the necessary conditions for successful cell transfer were obtained by irradiation.

(4) The number of cells necessary to achieve the anaphylactic state in irradiated recipient animals was evidently much smaller than in the case of normal recipient animals[4].

Agarophoresis and Immuno-electrophoresis of the Proteins of Gastric Juice

A NUMBER of authors have used paper and freely moving boundary electrophoresis for investigating proteins of gastric juice. We have tried to add to the results obtained by these methods by using electrophoresis in agar[1] and immuno-electrophoresis[2]. With these methods, especially in the case of immuno-electrophoresis, we found that there exists a fundamental difference in the behaviour of acid and anacid gastric juices.

Agarophoresis. The electrophoretograms of fifteen anacid gastric juices (*p*H 4–7) of patients with histamine-resistant achlorhydria showed five protein fractions, the mobility of which corresponded to that of serum proteins (Table 1, Fig. 1*a*). In three anacid gastric juices where all subsequent portions contained free hydrochloric acid after stimulation by histamine, two additional zones faster than albumin were observed. The electrophoretic mobility of this pre-albumin is identical with that of crystalline pepsin. In ten acid gastric juices seven fractions including two pre-albumin zones of pepsin were noted (Table 1, Fig. 1*c*).

Table 1. PROTEIN FRACTIONS OF GASTRIC JUICE AFTER ELECTROPHORESIS SEPARATION IN AGAR

Samples	Pepsin 2 ×	Albumin	Globulins				
			α_1	α_2	β_1	β_2	γ
15 anacid gastric juice	—	15	—	7	15	15	12
3 anacid gastric juice	3	3	1	3	3	3	3
10 anacid gastric juice	10	10	2	8	6	10	—

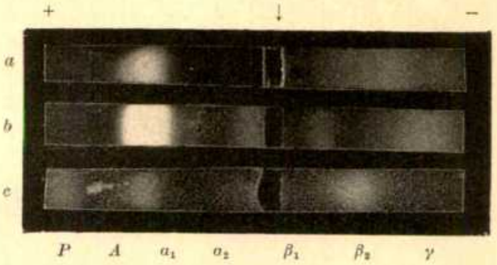

Fig. 1. Electrophoresis in agar: *a*, anacid gastric juice; *b*, serum; *c*, acid gastric juice

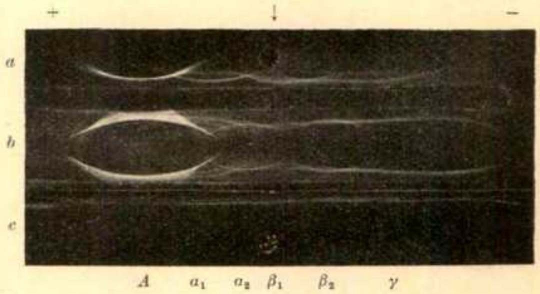

Fig. 2. Immuno-electrophoresis: *a*, anacid gastric juice; *b*, serum; *c*, acid gastric juice

Immuno-electrophoresis. The proteins of 22 anacid gastric juices precipitated on immuno-electrophoretic plates by rabbit antihuman serum developed 3–10 precipitation lines (Fig. 2). Their location both in the direction of electrophoresis and of diffusion corresponded to the precipitation lines of blood serum. In the double diffusion test[3] the albumin of the gastric juice gave the identity reaction with serum albumin. γ-Globulin reacted likewise with γ-globulin antiserum. The precipitation line of β_2-globulin was only about 30 per cent determined, although a zone of strong density was observed in all gastric juices by simple agarophoresis. This indicates that in all anacid gastric juices besides β_2-globulin, which is not precipitated by antihuman serum and thus differs immunologically from serum proteins, an inconstant serum β_2-globulin in lower concentration is present.

The proteins of ten acid gastric juices were not precipitated with antihuman rabbit serum. It follows from our investigation on the influence of single components of gastric juice on serum proteins that the protein fractions lose their immunochemical properties by the action of the activity of pepsin and the acid medium in dependence on time.

Attachment of Antibody to Influenza Virus

A KINETIC analysis of the neutralization of influenza virus by rabbit antibody indicated that the combination proceeds in two stages[1]. The first stage is the formation of a freely dissociable union between the virus and antibody. This is followed by a second stage which leads to the stabilization of the complex between the virus and antibody. The reaction kinetics also indicated that a single antibody molecule could form a stable combination with the virus particle. In an attempt to elucidate the nature of the stage of stabilization, the interaction between influenza virus and the univalent antibody fragments, produced by papain digestion[2], was investigated[3]. This investigation demonstrated that although the monovalent fragments could combine reversibly with the virus and neutralize its infectivity, they were unable to form a stable combination with the virus. It could be concluded that the stabilization of the combination between the virus and antibody depended on the divalent nature of the antibody molecule. On the basis of the foregoing conclusions and observations the following hypothesis emerged. The first stage in neutralization would be the attachment of the antibody molecule to the surface of the virus through one combining site and the second and stabilizing stage would be brought about by the attachment of the second combining site on the divalent antibody molecule to the same virus particle.

This hypothesis was supported by the finding that the fraction of virus particles which could undergo the stabilization reaction declined sharply when the reaction was studied in the region of extreme antibody excess[3]. This would be expected for the following reason. The stabilization stage proceeds at a much slower rate than the first stage of the interaction between virus and antibody. Thus, when the virus is mixed with high concentrations of antibody, antigenic sites on the surface of the virus particle will be rapidly occupied by antibody molecules attached through only one combining site. The combining sites of the virus will be saturated with antibody and the neighbouring molecules may sterically hinder the attachment of any antibody molecule to one and the same virus by both its combining sites. Indeed, work on the interaction between tobacco mosaic virus and antibody, carried out with the aid of the electron microscope, demonstrates that in the region of antibody excess the antibody molecules are attached to the virus surface through one combining site, with their long axes radiating out from the surface of the particle[4,5]. A similar type of combination has been observed in these Laboratories in work on the interaction between influenza virus and a large excess of antibody.

The kinetic evidence demonstrated the occurrence of a reaction of stabilization, but could not provide detailed information on the mechanism of the stabilization reaction. The following experiment was therefore conducted in an attempt to obtain more direct information on this point. Purified influenza A virus (*MEL*) was mixed with a solution of the globulins obtained from an *MEL* virus rabbit antiserum and held at room temperature for 4 hr. The concentration of the virus in the mixture was 4×10^4 hæmagglutination units/ml. and the concentration of antibody was 300 hæmagglutination inhibition units/ml. Virus and antibody titrations were carried out as described by Fazekas de St. Groth *et al.*[6,7]. The complexes of virus and antibody were sedimented in the ultracentrifuge, washed with saline and finally resuspended in distilled water. As a control, a preparation of *MEL* virus that had not been mixed with antibody was treated in the same way as the mixture of virus and antibody.

Specimens of the two suspensions were prepared for electron microscopy by mixing equal volumes of the suspensions and a 1 per cent solution of sodium phosphotungstate[8]. A drop of this suspension was allowed to dry on carbon-coated 'Formvar' membranes and the specimens were observed in the electron microscope (Siemens Elmiskop I). Fig. 1*a* shows the morphology of the virus particle and Fig. 1*b* the type of complex formed when the virus reacts with antibody. It can be seen that the antibody molecules become attached to the terminal ends of the sub-units which constitute the surface of the virus. The antibody molecules appear to be attached to the individual virus particle through both sites situated at the extremities of the antibody molecule, thus forming a loop on the surface of the virus particle.

It is known that the two combining sites on an antibody molecule have identical specificities[9,10]. This may well imply that the combining strength at each site is very similar. If this were so, the combination of the antibody with a virus particle through both combining sites of the antibody molecule would be much more stable than the combination through only one site, provided the strain introduced by the bending of the molecule did not significantly reduce the strength of the bonds formed through each combining site. The fact that a two-site attachment rather than a single-site attachment is produced when the virus and antibody react under conditions where the antibody is not in very large excess indicates that the former type of attachment is more stable than the latter.

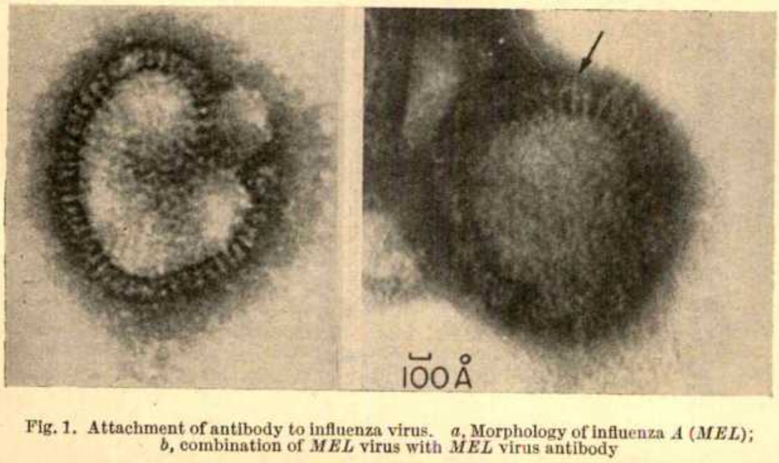

Fig. 1. Attachment of antibody to influenza virus. *a*, Morphology of influenza *A* (*MEL*); *b*, combination of *MEL* virus with *MEL* virus antibody

Thus, the observation of two-site combination between virus and antibody provides a physical mechanism which would account for the stabilization reaction.

A more detailed publication demonstrating the effect of the concentration of the reactants on the type of combination formed is in preparation

HÆMATOLOGY

Absence of Red Cell Enzyme Deficiency in Australian Aborigines

The geographical distribution of erythrocyte glucose-6-phosphate dehydrogenase deficiency is now known to be widespread Thus, this genetically determined enzyme defect has been shown to be present in parts of Africa, Asia and Europe, and in some Indian groups in South America[1]. Marked variations in the incidence of the defect have been observed between different populations and in some instances between different groups in the same population. In south-east Asia recent work has shown the trait to be present in Thais[2], Malays[2a], Indonesians (Lie-Injo, L E , personal communication), Filipinos[3] and Melanesians[4]

In the present work, using the rapid screening test described by Motulsky[5], a total of 722 Australian Aborigines were examined for evidence of glucose-6-phosphate dehydrogenase deficiency The subjects tested live in scattered areas of northern, central and western Australia All have tribal affiliations The groups studied are shown in Table 1

Table 1

Area	Males	Females	Total
Cape York Peninsula			
Edward River	43	45	88
Mitchell River	84	62	146
Lockhart River	27	—	27
Aurukun	39	37	76
Weipa	12	29	41
Wrotham Park	12	11	23
Central Australia			
Alice Springs	140	—	140
Western Australia			
Port Hedland	40	59	99
Marble Bar	11	13	24
Nullagine	27	31	58
Total	435	287	722

No cases of enzyme deficiency were found in this large population sample, indicating that the gene frequency is extremely low or non-existent. This finding is of interest in several respects Except for occasional cases of malaria introduced in recent times from surrounding areas Australia is malaria-free. The incidence of red cell enzyme deficiency has been shown, in Africa[3,6], New Guinea[4,7] and Sardinia[8], to be related to that of falciparum malaria, probably representing a selective advantage by way of increased resistance to malarial mortality Absence of the deficiency in Australian Aborigines supports this concept, as there would be no such advantage enhancing the survival of affected people in Australia

Glucose-6-phosphate dehydrogenase deficiency has an incidence as high as 20 per cent in males of coastal New Guinea[7] The penetration of the blood group *B* gene in Aborigines of the Cape York Peninsula groups is accepted as representing admixture from New Guinea[9] It is evident, however, that this penetration has not resulted in the introduction of the enzyme deficiency, or, if the gene has been introduced in the past, it has not survived That the well-known Malay contact with Aborigines in several areas of the north and north-west coast has not resulted in the introduction of the trait is not surprising, since its incidence in Malays is low, probably less than 1 per cent

Absence of this deficiency of red cell enzyme, then, adds important evidence to that already accumulated, including the absence of thalassæmia and the abnormal hæmoglobins, which demonstrates the degree of isolation of the Aborigines from surrounding peoples This trait will serve as an additional link in the chain that may eventually disclose the origin of the Australian Aborigines

Gratitude is expressed to Dr P Dawes and Miss M. Distribution of Haptoglobin Types in Israel

The interest in the patterns of haptoglobin types has been furthered during the past several years due to the introduction of starch-gel electrophoresis for their demonstration[1] Different populations have been investigated up to now[2,3].

Since differences between Jewish ethnic groups in Israel were described in relation to blood group patterns[4], incidence of erythrocyte glucose-6-phosphate dehydrogenase deficiency[5], and taste sensitivity to thiourea (Sheba, Ch , Ashkenazi, I , and Szeinberg, A., personal communication), it was of interest to investigate the haptoglobin patterns among them

Blood specimens from 526 blood donors from the blood bank of Tel Hashomer Hospital, and from patients without any serious illness, were examined. The material consisted of 170 Ashkenasi Jews (East European origin), 118 Iraqi Jews (Babylonians), 104 North African Jews (Morocco, Tunisia, Algeria and

Lybia) and 134 mixed population. The method used was vertical starch-gel electrophoresis as described by Smithies[6]. The starch was sliced longitudinally into two parts, one was stained with benzidine, the other with brom-phenol blue or amido-black 10 *B*. To the sera 120–150 mgm. per cent of oxyhæmoglobin was added to saturate the haptoglobins completely. The results are presented in Table 1.

Table 1. HAPTOGLOBIN TYPES AND FREQUENCY OF ALLELE Hp^1 AMONG DIFFERENT ETHNIC GROUPS IN ISRAEL

Group	No. tested	*Hp* 1–1		*Hp* 2–1		*Hp* 2–1 *M*		*Hp* 2–2		Gene frequency Hp^1
		No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	
Ashkenazi	170	13	7.65	88	51.76	—	—	69	40.59	0.34
Iraqi	118	9	7.63	50	42.37	—	—	59	50.00	0.29
North African	104	8	7.69	43	41.35	1	0.96	52	50.00	0.29
Rest of population	134	13	9.70	51	38.06	—	—	70	52.24	0.29

No cases of ahaptoglobinæmia were found except in hæmolytic anæmias, which are not included in this work. Only one case of 2–1 *M* was found, that being among the North African Jews. The gene frequency of Hp^1 in Ashkenazi Jews was found to be 0.34, while that found among the Iraqi and the North African Jews was 0.29. This difference is not statistically significant. The expected values of phenotype were calculated on the basis of the Hardy–Weinberg equilibrium and were found to correspond closely to the observed numbers.

Our results show that the frequency of Hp^1 among the Ashkenazi Jews is similar to that found in European populations[2], while the Iraqi and North African Jews have a lower frequency of Hp^1 similar to that found in Asian populations[3]. Other Jewish and Arab populations are under investigation.

Distribution of Group-specific Components (*Gc*) in the Sera of Native Africans

THE group-specific components of sera consist of electrophoretically variable α_2-globulins demonstrable by means of an immuno-electrophoretic technique[1]. This system allows a division of human sera into three qualitatively different patterns characterized by the presence of a fast-moving group-specific component (*Gc* 1–1), a slow-moving component (*Gc* 2–2), which in immuno-electrophoresis both give normally arc-shaped precipitates, or the simultaneous presence of both fast- and slow-moving components (*Gc* 2–1), which in immuno-electrophoresis give an extended two-peaked precipitate due to a reaction of immunological identity between these electrophoretically different although immunologically identical fast- and slow-moving components[1]. Investigations on sera from 42 families with 137 children and more than 600 mother–child combinations have shown that these serum patterns are genetically determined by two autosomal alleles (Gc^1 and Gc^2) without dominance where the serum types *Gc* 1–1 and *Gc* 2–2 are the homozygotes and *Gc* 2–1 the heterozygote. Up to now, no exceptions to this genetical theory or unresolved typing difficulties has been found in the material investigated[2,3].

Table 1. FREQUENCIES OF THE Gc^1-GENE IN VARIOUS POPULATIONS

Table 2. DISTRIBUTION OF *Gc*-TYPES IN SERA FROM 100 AFRICANS

	Gc 1–1	*Gc* 2–1	*Gc* 2–2	Gc^1
obs.	82	17	1	0.91
exp.	81.9	17.2	0.9	

The frequencies of the Gc^1-gene in populations hitherto investigated are given in Table 1. In Table 2, the distribution of *Gc* in a serum sample consisting of sera from 100 native Africans collected in Léopoldville, Congo, are given. The results seem to show that the system might be of value in connexion with anthropological investigations, and further work concerning the distribution of *Gc*-types in different populations is in progress.

One of us (J. H.) gratefully acknowledges a grant from Lennanders Fond, Uppsala, Sweden.

Note added in proof. A more detailed survey of the distribution and inheritance of the *Gc*-system will be given elsewhere[3].

RADIOBIOLOGY

Autoradiographic Study of Cell Migration during Histogenesis of Cerebral Cortex in the Mouse

AUTORADIOGRAPHY with thymidine labelled with tritium has proved useful for the study of histogenesis in the mammalian brain[1–6]. Labelled thymidine injected into animals becomes incorporated almost exclusively into deoxyribonucleic acid of cells preparing to divide and remains in their nuclei as a permanent label, the radioactivity is diluted to half with each cell division[7]. When the autoradiographic method is applied to tissues of animals killed serially, one can determine the time and place of origin of cells, their route and rate of migration, and their ultimate fate.

The question has been raised as to whether cells which appear to change position during development are truly migrating or are merely being displaced by cells which form at subsequent stages. The present work demonstrates that migrations of cells do indeed take place in the developing brain.

Tritiated thymidine (5 μc./gm. of body-weight) was injected once intravenously into pregnant mice. The animals were injected in pairs on the 11th, 13th, 15th, or 17th days of gestation. One animal of each pair was killed 1 hr. after injection, and offspring of the other injected animal were killed on the 10th postnatal day. Brains were processed for autoradiography as described elsewhere[1].

In an embryo killed 1 hr. after injection on the 11th day, the telencephalic vesicle consists only of a primitive ependymal zone; most of its cells are labelled, as has been observed previously[1]. Many of the primitive ependymal cells later migrate outward to form the anlage of the cortical plate. In embryos injected on the 13th, 15th, or 17th day of gestation and killed 1 hr. later, the cerebrum shows labelled cells almost exclusively in the primitive ependyma and relatively few in the developing cortical plate. Thus, the source of most cortical cells is the primitive ependyma of the lateral ventricles. After mitosis in the primitive ependyma, cells migrate outward to form the cortical plate and differentiate into its constituent neurons.

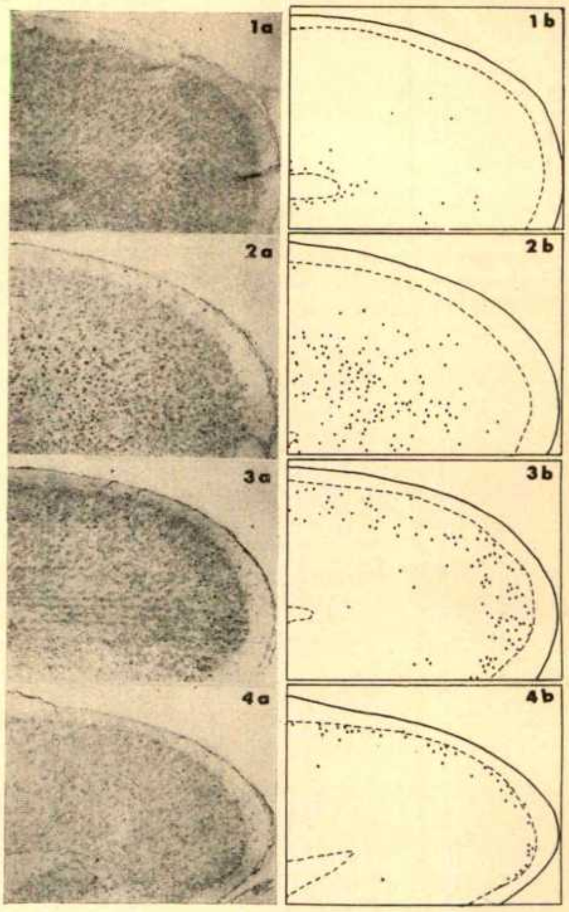
To study the postnatal disposition of cortical cells arising in the 11-, 13-, 15-, and 17-day embryos, we photographed the entire anteroposterior extent of the cerebral cortex of the corresponding four 10-day old mice. For each brain a series of overlapping photomicrographs was made at a magnification of 150 diameters on 4 × 5 in. sheet film, and prints were assembled as a montage to show the distribution of labelled cells. Comparable sections of occipital cortex from the 4 mice are illustrated in Figs. 1–4 and the following description refers to this region of cortex.

Many cells labelled on the 11th day of gestation undergo only 1 or 2 further divisions and are recognized in the brain of the 10-day old animal as heavily labelled cells. These cells are almost exclusively in the deepest part of the cortex adjacent to the white matter (Fig. 1). Other cells labelled on embryonic day 11 divided on subsequent embryonic days and appear in the 10-day old mouse as weakly labelled cells scattered through all cortical layers.

The mouse labelled on the 13th day of gestation and killed 10 days after birth shows a greater number of heavily labelled cells; these are located predominantly in the middle third of the cortex (Fig. 2). These cells originated later than the cells which arose on the 11th embryonic day and migrated past their predecessors upon entering the cortical grey matter.

The same pattern of origin and migration obtains for cells forming later in gestation. Cells which arise on the 15th embryonic day migrate past cells which had formed earlier and come to lie in the outermost third of the cortex (Fig. 3). Relatively few cells arising on the 17th embryonic day are destined for the occipital cortex; these migrate to the most superficial cell layer, the presumptive lamina ii (Fig. 4).

As Figs. 1–4 show, cells originating on any particular embryonic day come predominantly but not exclusively into a given cortical level. Cells forming successively later in embryonic life migrate outward past their predecessors and come to lie at more and more superficial levels. The correlation between these levels and cortical laminæ as conventionally designated will be considered in a more complete account of cortical histogenesis now in preparation.



Figs. 1–4. Photomicrographs (*a*) and matching drawings (*b*) of comparable parasagittal sections of occipital cortex from four 10-day-old mice injected with thymidine labelled with tritium on the eleventh, thirteenth, fifteenth and seventeenth days of gestation respectively. Dots in drawings indicate heavily labelled cells. Intensity of labelling in photomicrographs varies because tissues were exposed to the emulsion for different durations prior to development of the autoradiograms. Outer broken line represents inner boundary of molecular layer of cortex and inner broken line the boundary between cortex and white matter. (× *c*. 38)

Cortical zones other than occipital cortex display a similar pattern of histogenesis. The times of origin and migration of cells into other cortical regions differ from the times described for occipital cortex.

If cells do not migrate outward, but are merely displaced peripherally by new cells which arise afterwards in the primitive ependyma, one would expect the more superficial layers of cortex to form first and the deep layers last, as has been suggested[8]. Our autoradiographic results indicate just the reverse, and show that cells do migrate extensively in the developing mammalian cerebrum.

This curious reverse order of formation of cortical layers may have significance for the attainment of intracortical synaptic connexions. It is recognized that the axons of most cortical neurones are directed inward toward the white matter and that their dendrites are directed outward[9]. The orientation of the circuits established by synaptic contact of these processes is predominantly perpendicular to the plane of the cortex[10]. These synaptic contacts might be attained during the histogenetic period, as cells migrate past those neurones that have arrived previously in the developing cortex. The perikaryon of a cell migrating outward may perhaps establish contact with another cell already in position in the cortex and may then migrate farther while trailing its axon behind, still in contact with the perikaryon or the developing dendritic tree of the cell that had arrived previously. The cell contacts established during histogenetic migration may also be relevant for the formation of particular patterns of synaptic connexions in other parts of the nervous system, as discussed elsewhere[3,4].

Uptake and Incorporation of Tritiated Thymidine in *in vitro* Culture

THE duration of the 'synthesis phase' of deoxyribonucleic acid (DNA) of the mitotic cycle (phase *S* of Howard 1956[1] and Lajtha *et al.* 1954[2]) has been determined for several cell types. As yet no distinction has been made between the uptake of labelled thymidine and its incorporation by the cell into a more complex structure, presumably DNA.

Sagittal slices of the upper tibial epiphysis of the rat, rabbit and guinea pig were cultured *in vitro*, in the presence of tritiated thymidine (0·5–1 μc. tritiated thymidine, specific activity 0·360 c./m.mol., to 5–6 ml. medium), in an attempt to elucidate the growth pattern of the epiphyseal growth cartilage and the articular cartilage. The explants were fixed in 10 per cent formalin at *p*H 7·4–7·6. Some were embedded in butyl and isobutyl methacrylate and sectioned without decalcification; others were first decalcified with 10 per cent formic acid for 12 hr. before being embedded in paraffin wax. Sections 4–7μ thick were cut, the embedding medium removed, and autoradiographs made according to the Pelc stripping film technique[3], and exposed for 3–6 weeks. Grain counts were made on cells in the proliferative zone (flattened cells) of the epiphyseal growth cartilage.

If the tissue was sectioned without previous decalcification, the grain counts attained nearly the maximum value after ½ hr. in culture. By 1 hr. the maximum value was found; this persisted for the duration of the experiment (Fig. 1).

On the other hand, if the tissue was first decalcified with formic acid, maximum counts were only attained on explants that had been cultured for 6–9 hr. (Fig. 2, rat). Similar results were obtained by giving the tritiated thymidine to rats *in vivo*.

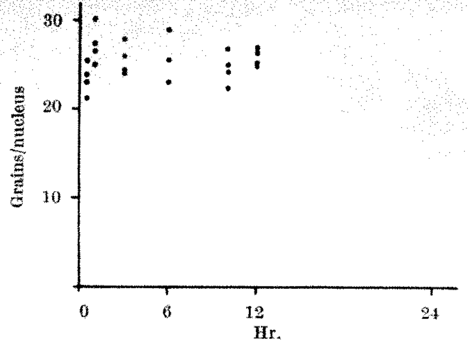

Fig. 1

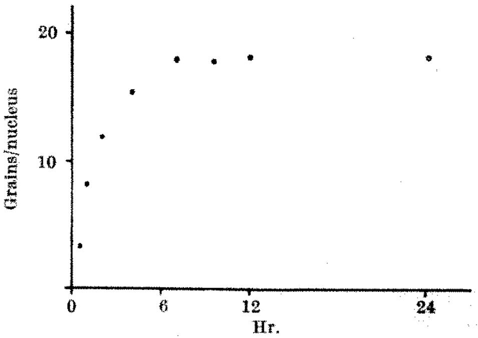

Fig. 2

These results suggest that a maximum load of tritiated thymidine is taken into the cell nucleus very rapidly. In fact, this occurs so rapidly, in less than 1 hr., that a carrier mechanism might have to be invoked to explain it. But once in the nucleus, it takes a finite time for the tritium-labelled substance to be incorporated into a large and more complex molecule capable of resisting removal by 10 per cent formic acid. This process of incorporation would appear to take between 6 and 9 hr. to be completed in the cells of the proliferative zone of the epiphyseal growth cartilage.

BIOLOGY

Fluctuations in Marine Populations in Icelandic Waters

IT is well known that populations of many animals living at high latitudes are subject to considerable fluctuations. Fairly regular periodic variations are reported in a number of cases. The 10-yr. cycle of the rock ptarmigan in Iceland reported by Gudmundsson[1] furnishes a striking example. The cause of this cycle is unknown.

Marine populations are also subject to large fluctuations but there are few reports on regular or periodic variations. This may in many cases be due to lack of observations.

There are available fairly reliable data on the catching of cod in the waters south-west of Iceland since 1900. In particular, there is available a set of data of a rather uniform quality for the winter

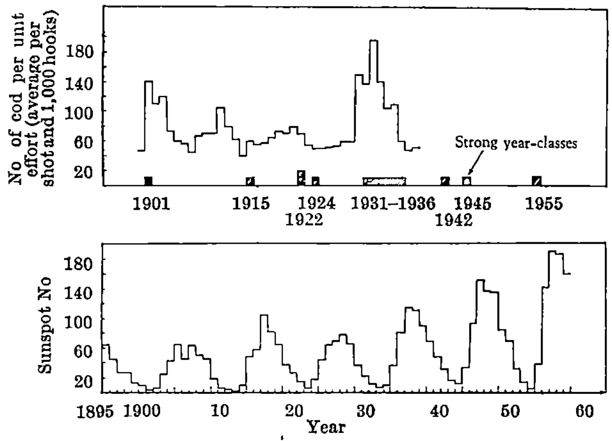

Fig. 1. Catch of cod per unit effort in the Vestmanna Islands during 1900–40, and its relation to observed strong year-classes and the sunspot number

seasons during 1900–40. Data on the catch per unit effort have been collected in the Vestmanna Islands and are given as the yearly average number of cod caught per shot and 1,000 hooks. The data are given in Fig. 1. Unfortunately these data have not been collected for the period since 1940.

The catch per unit effort given in Fig. 1 is subject to a rather regular variation with a period of approximately 10 yr. This happens to be the same period as that of the rock ptarmigan. There is little doubt that the catch per unit effort depends largely on the number of individuals per unit volume, and the data therefore give a certain measure of the variation in the size of the spawning stock.

The fluctuations in the strength of the spawning stock of cod are due to pronounced differences in the strength of the individual year-classes. Certain year-classes prevail in the commercial catch. The recruitment age for more than 80 per cent of the stock is 7–10 yr.

Reliable data are available on the strength of individual year-classes since 1920. Moreover, it is known that the 1901 and 1915 year-classes were relatively strong although very little is known about other year-classes during 1900–20.

The prevailing year-classes are given in Fig. 1. There appears to be a tendency for an 11-yr period in the emergence of strong year-classes. The class of 1915 is somewhat anomalous, and the period 1931–1936 is characterized by a series of medium-size classes. This, however, does not interfere with the rather regular pattern.

For several decades it has been repeatedly pointed out that certain biological phenomena appear to exhibit periodicities related to the 11-yr solar cycle. In most cases, however, the evidence has been very weak and there have been no reliable indications as to the relation between the solar and the biological phenomena.

Quite recently, however, it has been pointed out by MacDonald and Roberts[3] that solar corpuscular emission may affect the surface weather in a significant way. Also, Landsberg *et al.*[4] have been able to detect a weak tendency for a sunspot rhythm in the temperature of the United States.

In view of these circumstances we have compared the emergence of strong year-classes of the Icelandic cod with the sunspot rhythm. The Zurich sunspot number has been plotted in Fig. 1. The results at hand indicate quite definitely that the strong year-classes emerge preferably during periods of low solar activity.

In order to extend these observations we have studied the available reports on the catch of other species in Icelandic waters. Unfortunately these reports are much less reliable than the above data on the catches of cod. However, the results are not altogether negative.

The catch of herring during the summer season in the waters north of Iceland, measured in volume per boat, exhibits relative maxima in 1923, 1933 and 1944. These are years of low solar activity. Moreover, the total catch of salmon in the rivers of Iceland, measured in number of salmon per annum, exhibits pronounced maxima in 1913, 1922 and 1933, which are years of low solar activity. On the other hand, the available data on the total catch of lumpfish in Icelandic waters exhibits maxima in the periods of high solar activity. Data on lumpfish are at hand for 1915–50. The maxima correlate moderately well with the solar maxima of 1917, 1928 and 1938.

A discussion of possible causes of the more or less apparent correlation between the solar rhythm and biological phenomena is beyond the scope of this communication. We realize, of course, that the fluctuations of the populations may be due to some local or internal cause and the relation to the solar rhythm only accidental.

In order to look for a climatic factor we have made a preliminary investigation of the solar-weather relationship for Iceland during 1900–60. The fluctuations in the annual and the monthly means of the temperature and the precipitation in Reykjavik have been investigated. The results are negative so far. No relation to the solar rhythm has been detected. However, we wish to emphasize the preliminary nature of this work.

Colour and Density of Light and Broiler Performance

It has been shown that some form of artificial lighting is necessary to achieve the most rapid gains of weight in broilers[1]. With controlled environments, light intensities of 0.1–6.0 ft.-c. gave equally good growth-rates in broiler chicks during the first eighteen days, and 12.0–24.0 ft.-c. produced slightly depressed growth-rates during this period[2]. A field scale survey has noted that in many broiler houses in Britain the light intensity is maintained at 0.05–0.20 ft.-c. as a control measure for the prevention of cannibalism[3]. An experiment is being conducted which has already compared three types of continuous lighting in relation to broiler performance.

Six groups, each of 111 Rhode Island Red × Light Sussex cockerels hatched on August 27, 1960, were reared under identical conditions except for variations of light in environmental chambers 14 × 8 ft. Two groups served as controls and their chambers were each lighted by two 15-W white incandescent

Table 1. WATER CONSUMPTION, MORTALITY AND GROWTH TO 7 DAYS OF AGE

Lighting treatment	Mean water consumption (pints) per pen First 3 days	Mean water consumption (pints) per pen First 7 days	Mean water consumption (pints) per survivor First 7 days	No. mortalities per pen during first 7 days	Weight increases per chick during first 7 days (oz.)
Controls	11.2	35.5	0.323	1.0	2.47
Dull red	9.2*	30.0	0.284	5.5*	2.12*
Dull white	10.5	34.0	0.313	2.5	2.26
Least difference to be significant between two means, $P < 0.05$	1.0	4.3	N.S.	1.9	0.15

N.S., no significant difference.

* Significantly different from the control, $P < 0.01$.

Table 2. AVERAGE RESULTS TO 72 DAYS OF AGE

Lighting treatment	Mean No. mortalities per pen	Live-weight (lb.) Total per pen	Live-weight (lb.) Average per broiler	Food consumption (lb.) Total per pen	Food consumption (lb.) Average per broiler	Food efficiency (food consumed per unit of live-weight gain)
Controls	1.0	402.7	3.661	1085.7	9.87	2.696
Dull red	7.5*	367.6*	3.552	976.0*	9.43*	2.655
Dull white	3.5†	387.8†	3.607	1009.5*†	9.41*	2.603*
Least difference to be significant between two means $P < 0.05$	1.9	10.6	0.101	3.3	0.21	0.043

* Significantly different from the control, $P < 0.01$,

† Significantly different from the dull red treatment, $P < 0.01$.

bulbs. Two further pens each had two 40-W. red bulbs and the remaining two had two 5–8-W. white economy bulbs. Lighting was continuous, and the intensities recorded were 0.20–0.50 ft.-c. in the control pens, and 0.05–0.10 ft.-c. in the other four pens which were lighted by dull white and dull red bulbs.

During the first few days the form of lighting affected the amount of water consumed. This is shown in Table 1. Differences in mortality and growth-rates to one week of age were also apparent. The use of dull red lighting was associated with increased mortality compared with the control ($P < 0.05$). At the end of the first week the controls were heavier per survivor than the birds of either of the two experimental groups ($P < 0.05$ dull white lighting, $P < 0.01$ dull red lighting).

Table 2 shows the results to 72 days of age. The control chicks ate significantly more per pen and more per bird than did either of the two experimental treatments. Although the total live-weight of the controls was greater than that of either of the other two experimental groups ($P < 0.05$ dull white lighting, $P < 0.01$ dull red lighting), the average live-weight of the controls was only significantly heavier than the broilers reared under the dull red lighting. These variations were partly due to differences in mortality. The birds receiving dull white light had an improved food conversion factor compared with the control ($P < 0.01$) and compared with those receiving the dull red treatment ($P < 0.05$). No cannibalism was observed under any treatment, and there was no downgrading because of stubby, undeveloped feathers when the broilers were sold.

This experiment, which is being extended, is conducted with the aid of grants and equipment from the Agricultural Research Council, Calor Gas, Ltd., Electrical Development Association, Fenton Byrn, Ltd., Maywick Appliances, Ltd., and Wernick Construction Co., Ltd., in the Department of Animal Husbandry at the Royal Veterinary College, London.

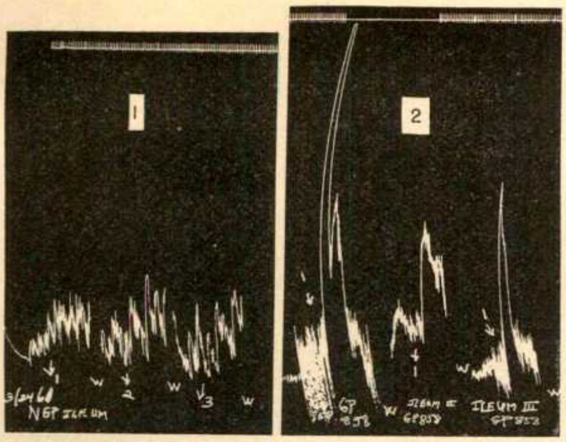
Antigenicity of Guinea Pig Testicular Cells grown in Cell Culture as determined by the Isolated Ileum Technique

I HAVE previously recorded experiments relating to the antigenicity of testicular tissue and of sperm as well as extracts thereof[1]. For many reasons, for example to facilitate identification of spermatogenic tissue antigens and to elucidate the mechanism(s) of cell destruction occurring in immunologically induced aspermatogenesis, it was important to have replicating cell cultures of testicular tissue. Replication, rather than mere maintenance, of testicular cells in culture has recently been accomplished, and the results will be published *in extenso* elsewhere. The attainment of this goal imposed the requirement of demonstrating that spermatogenic cells grown in culture continue to synthesize antigens that are present in the germinal epithelium of the testicle *in vivo*. Among such antigens are those capable of (1) eliciting anaphylactic contracture of sensitized ilea, (2) inducing aspermatogenesis, (3) provoking the production of humoral antibody. We have found that replicating guinea pig cells carried in culture for more than 2 months are capable of causing anaphylactic contracture of sensitized ilea and can also be used to sensitize guinea pigs.

Eight adult male guinea pigs (600–700 gm.) were injected with guinea pig testicular homogenate in Freund's adjuvant. The preparation of the adjuvant–antigen mixture and the method of injection have already been described[1]. Briefly, a weighed amount of testicular tissue is homogenized in an equal volume of 0.9 per cent sodium chloride solution and the homogenate is then incorporated into an equal volume of the adjuvant so as to form a stiff gel. This preparation is injected intracutaneously in 6–8 sites in the nuchal region of the male guinea pigs. Three weeks after injection, 4–5-cm. segments of the ileum are removed from these animals and suspended in an oxygenated bath of Locke–Ringer's solution. When challenged with specific antigen (homologous sperm or purified extracts thereof), these segments contract anaphylactically. This test has been found to be a consistently reliable indicator of the presence of antibody to spermatogenic antigen(s). In the present work, therefore, the presence of spermatogenic antigen(s) in the cell cultures of the guinea pig testicular tissue was determined by using the cell



Figs. 1 and 2. (1) An ileal segment of a non-sensitized guinea pig is not caused to contract when challenged with three different cell cultures of (at 1, 2 and 3, respectively) guinea pig testis. (2) Ileal segments from a guinea pig sensitized with homologous testis homogenate contract anaphylactically when challenged with the same three cell cultures noted in Fig. 1

cultures to challenge ileal segments of guinea pigs sensitized with whole testicular homogenate and by using homologous sperm to challenge ileal segments of guinea pigs sensitized with the cell cultures of guinea pig spermatogenic tissue.

Experimental Series I. Ileal segments from non-sensitized guinea pigs were suspended *in vitro* and challenged with three different cultures of guinea pig testicular cells that were collected 2 months following initiation of the cultures. The cells were separated from the culture media by centrifugation and were suspended in Locke–Ringer's solution (1 ml. : 0·5 ml. of packed cells) so that approximately $3 \cdot 3 \times 10^7$ cells were present per ml. of fluid. The cells were then homogenized in a glass hand homogenizer and 1·0 ml. of the homogenate was added to the bath fluid containing the ileum. Responses of the segments of ileum were recorded with the aid of a kymograph.

Experimental Series II. Segments of ileum from guinea pigs sensitized with homologous testicular homogenate were challenged with the following: (1) homologous spermatozoa; (2) the three preparations of cell cultures used in experimental series I (above); (3) a concentrate of the tissue culture media separated from the cultured cells by centrifugation.

Experimental Series III. Eight male guinea pigs were injected with the three cell cultures homogenized in saline and incorporated into Freund's adjuvant. Three weeks later, segments of the ilea of these animals were challenged with homologous sperm.

The homogenized cultured spermatogenic cells did not cause contracture of ileal segments from non-sensitized guinea pigs. This is illustrated in Fig. 1, a kymograph tracing demonstrating that not one of the three preparations (injected into the bath at 1, 2, and 3, respectively) affected the tonus of the segment. Moreover, the media in which the cells were grown did not cause contraction of ileal segments from non-sensitized or sensitized animals.

In sharp contrast are the responses of ileal segments of sensitized animals when challenged with the same three cell culture preparations. In Fig. 2 it is apparent that each of the cell homogenates caused a strong contracture (at 1, 2, and 3, respectively) of an ileal segment from a guinea pig injected with whole testicular homogenate. Similar responses were obtained when ileal segments from animals sensitized with the cell culture homogenates were challenged with homologous sperm.

The results of these experiments indicate that guinea pig testicular cells grown in culture for more than 2 months contain antigens that can sensitize ilea and that elicit contracture of the ileum of sensitized guinea pigs. The antigens were not carried over from the original cells because the final cultures represent seven serial transfers and it is calculated that few, if any, of the original cells could have been present in the final populations employed. Thus, antigen synthesis *in vitro* must have occurred. These observations now make it possible to examine more definitely the problem of elucidating the mechanism(s) of cell destruction occurring in immunologically induced aspermatogenesis.

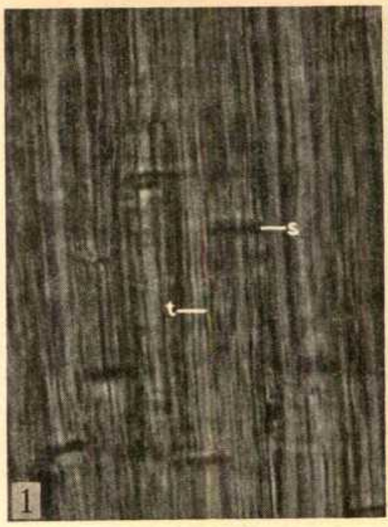
Cell Reduction in the Embryonic Development of the Cestode *Diorchis ransomi* Schultze, 1940

DURING work on the embryonic development of the cestode *Diorchis ransomi* Schultz, 1940, considerable attention was paid to the final phase called the pre-oncosphere. This phase is relatively little known so far. The present communication deals with only one feature of the pre-oncosphere, namely, the reduction in number of embryonic cells. A more detailed account of the work will be published in *Acta Parasitologica Polonica*.

The embryogenesis was investigated in 5μ-thick serial sections of gravid segments. The staining methods used were : Prenant's trichrome, Feulgen technique, Brachet technique and toluidine blue with a control hydrolysed by hydrochloric acid. As a result of the reconstruction of particular embryos from serial sections I was able to establish with reasonable accuracy the number of cells in subsequent developmental phases.

In the early embryos three types of cells were recognized : macromeres, mesomeres and micromeres. They were identified by their dimensions and nuclear structures. The mesomeres formed the outer membrane of the embryo. The other cells multiplied very intensively, the maximum number being 75–80. The majority of them were micromeres. The cytoplasm of early embryo cells was a syncytial one and ribonucleic acid (RNA) was shown to be present after treatment with the technique of Brachet.

The pre-oncosphere phase began after the formation of the outer membrane. Besides the other morphological and cytochemical changes, considerable cell reduction took place at this phase. The 75–80 cells previously observed in the embryo decreased, finally reaching about 26 in the fully formed oncosphere. At the same time the following cytochemical observations were made. After staining with the Feulgen reagent, two types of micromere nuclei were recognized. The first were homogeneous nuclei, which were very numerous, but irregular fragments of decomposed nuclei were also observed. The latter were nuclei with a distinct chromatin network and were relatively small in number. Simultaneously, the Brachet technique showed a considerable decrease in RNA in the syncytial micromere cytoplasm, which remained colourless with all the staining methods used. The mesomere nuclei did not show any particular change in the pre-oncosphere phase. The cytoplasm became compact and formed a clearly outlined layer around each nucleus. The Brachet technique and toluidine blue revealed a large increase of RNA content in the cytoplasm. This mesomere structure showed that these are the plastin cells described by Vogel[1].



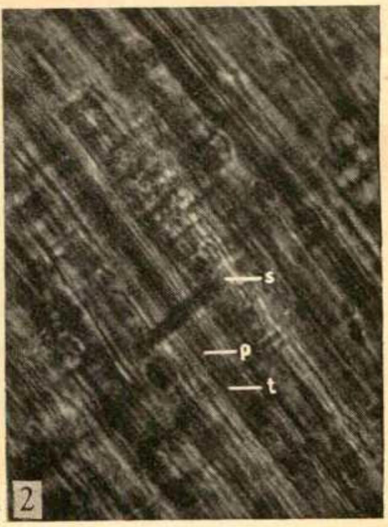


Fig. 1. A fresh hand section of *Primula* petiole phloem showing five sieve plates (*s*) crossed by parallel transcellular strands (*t*). The photomicrograph is an enlargement of a single frame from a 16-mm. ciné film. (× *c*. 1,730)

Fig. 2. A preparation similar to Fig. 1. Transcellular strands (*t*), in which particles (*p*) appear as bright spots and cross a single large sieve plate (*s*). (× *c*. 1,730)

In the fully formed oncosphere two types of cells were visible. There were 9–13 small nuclei with syncytial colourless cytoplasm in the hook region. About 12–16 plastin cells filled the oncosphere almost entirely. Their strongly basophilic cytoplasm was rich in RNA. Observations of the early metacestode of *D. ransomi* in its intermediate host *Cypridopsis vidua* (Mull.) showed the rapid growth and multiplication of plastin cells. The small nuclei of the hook region disappeared completely after the oncosphere reached the hæmocœl of the host.

In recent papers the only observation known to me on cell reduction in cestode embryos was made by Joyeux and Baer[2] in their work on *Catenotaenia pusilla* (Goeze). They did not, however, deal with the problem in detail.

Ogren[3], in his investigations on *Mesocestoides corti*, Hoeppli, observed the decrease of small cells in the final phase of embryonic development. In his opinion this was a result of the transformation of the small cells into compact plastin cells. The results obtained by me on *D. ransomi* do not seem to confirm Ogren's interpretation. The reduction of the total number of embryonic cells proved that some of the small cells had disappeared. The homogeneous nuclei seen in many micromeres supported this observation. According to recent research on the biological role of RNA (ref. 4) the disappearance of RNA from micromere cytoplasm indicates the lack of developmental potential.

Transcellular Strands and Particle Movement in Mature Sieve Tubes

I HAVE suggested elsewhere[1] that transcellular protoplasmic streaming is the major cause of translocation in vascular plants. The hypothesis depends on the existence of transcellular tubular strands which cross the sieve tube lumina and pass through sieve pores thus providing a structural basis for cytoplasmic communication throughout the vascular system. Within the tubular strands, microscopic structures, comparable with the thread-like constituents of hair cell cytoplasm[1] (and perhaps related to the endoplasmic reticulum seen in electron micrographs of plant cytoplasm[2,3]) are thought to be continuous in the longitudinal direction and to be surrounded by a fluid matrix.

The purpose of this communication is to report the observation of transcellular particle movements along these strands in living mature sieve tubes. Fresh hand sections of *Primula obconica* petiole phloem were mounted in 0·3 *M* sucrose solution and observed in transmitted light with a × 60 apochromatic objective. The observations have been recorded on 200 ft. of 16-mm. ciné film. Figs. 1 and 2 are individual frames taken from the ciné film and show the tissue in which moving particles were seen. Because the particles move within tubular strands they are not sharply defined in such single photomicrographs but they are easily seen in movement in the ciné film and the following statements are based on observations made on the film. Throughout the film, strands (*t*, Figs. 1 and 2) 1·5–2·0μ in diameter are seen in parallel arrangement in sieve tube elements and continuous across sieve plates. Particles (*p*, Fig. 2) can be observed to pass along the lumina of sieve tube elements, and through sieve plates, within transcellular strands and move in opposite directions in single sieve tubes, sometimes within adjacent strands. The particles occur approximately 3μ apart in close linear order in the strands, and their size is comparable with plant mitochondria (diam. 0·5μ). The rate of movement lies within the range 3–5 cm./hr., which is much slower than the translocation-rates recorded in experiments with whole plants, but it is not necessary to assume that particles are the only mobile contents of transcellular strands, and particles may move faster in the stems of plants with long internodes. Moreover, the speed and numbers of moving particles in hand-sections could be affected by slight damage caused in sectioning. The surprising fact is that transcellular particle movement has been observed through as many as ten sieve tube elements (total length 1·0 mm.) in the linear file of a single sieve tube, in spite of the damage done to transcellular strands at the cut ends of the section.

The particles presumably travel long distances through the phloem and could therefore be involved in transporting mobile materials from the leaf to the stem, the apex or the root. Although particles move past one another in adjacent strands they have not been observed changing direction and are probably part of a two-way transport system. Two-way movement without change of direction implies either that particles originate where transcellular movement begins and are assimilated at their destination or that particles are part of a circulation system in the plant. If the first explanation is correct, particles originating in the stem or root are assimilated in the mature leaf. It is difficult to accept this possibility because leaves export the products of photosynthesis in quantity and import only traces of mobile materials[4-6]. On the other hand, if a circulation system exists in the plant, particles could move out of the leaf loaded with mobile materials and then move back to the leaf after discharging their contents. Circulation streaming seems a more plausible explanation of two-way particle movement in the phloem, and it is interesting that particle circulation is known to occur as part of protoplasm streaming in hair cells.

I wish to thank Prof. Preston for his support and advice during this investigation.

MICROBIOLOGY

Effect of Ultra-Violet Radiation and Desiccation on Different Age-Cultures of *Escherichia coli K12*

DURING the course of an investigation on the effect of monochromatic ultra-violet radiation on *E. coli* some unusual observations were made concerning the sensitivity of different age-cultures to ultra-violet light and desiccation. A survey of literature[1-3] revealed conflicting reports on the subject. This work was undertaken to resolve the problem.

For investigating the effect of ultra-violet light on *E. coli* 0·04 ml. (one drop) of suitably diluted culture was spread on a clean sterile glass slide and exposed to ultra-violet radiation for 30 sec. at a distance of 45 cm from the source. A Hanovia 215-W quartz mercury lamp housed in an asbestos-lined metal box was used as a source. The exposed slide was then pressed on a nutrient agar Petri dish and gently removed after 15 min. The plates were incubated at 37° C. for 24 hr. This entire operation was carried out in very dim light. After the incubation period the developed colonies were counted. The controls were similarly and simultaneously prepared.

For desiccation work, the glass slides spread with a suitably diluted culture were placed in a metal box and dried at 37° C. in an incubator with the lid slightly open for 3 hr. After this period, the slides were treated as before. The control slides were similarly prepared, but immediately pressed on agar plates without allowing them to dry. These experiments were repeated several times with both glass and stainless steel slides which gave identical results. This eliminates the possibility of attributing the lethal effects to free alkali on the glass surface.

Table 1. EFFECT OF ULTRA-VIOLET RADIATION AND DESICCATION ON *E. coli*

Age of the *E. coli* culture (hr.)	Percentage viable colonies after drying	Percentage viable colonies after exposure to ultra-violet radiation
0·75	20·8	7·2
1·5	18·5	6·0
3	6·0	2·3
4·5	2·0	1·2
6	4·0	1·5
8	10·0	2·6
12	18·5	3·7
16	20·2	4·0
18	20·1	4·1
24	20·3	4·1

It will be seen from Table 1 that the 0·75-hr.-old culture (in the lag phase of growth) is most resistant to both ultra-violet radiation and desiccation, whereas the 4·5-hr.-old culture (in the logarithmic phase of growth) is least resistant to these agents. The 24-hr.-old culture (in the maximum stationary phase) is fairly resistant to both the ultra-violet light and desiccation.

The resistance of *E. coli* to ultra-violet light and desiccation seems to be a maximum in the lag phase and starts diminishing during early logarithmic phase and is regained as the culture reaches the maximum stationary phase. The resistance to desiccation seems to be completely regained after 24 hr., but the resistance to ultra-violet radiation is not completely regained even after 24 hr.

It has been observed (ref. 4) that during the later part of the lag phase the nucleic acid content, protein content and the cell size are at their maximum levels and start diminishing in logarithmic phase. It is also well known that the bacterial cells are not dividing in the lag phase and their cell walls and membranes are unbroken. It therefore appears that the intact cell membranes, the large amount of nucleic acids, etc., and the large cell size may be responsible for the resistance of the cells in this phase to ultra-violet radiation and desiccation.

It is interesting to note that work conducted on the effect of X-rays, heating, cooling, freezing and freeze-drying, seems to suggest that bacteria are less resistant to these agents in the logarithmic phase than in the stationary phase. It would be extremely informative to investigate the effects of these agents on the bacteria in the lag phase.

Spheroplasts of Marine Bacteria induced by the Action of Penicillin

SEVERAL species of marine bacteria which are characterized by osmotic dependence have been induced to form spheroplasts by the action of penicillin added to cultures growing optimally in a nutrient broth prepared with sea water. Two factors indicated the likelihood of obtaining this result. First, recent papers[1-3] have contained results indicating that the internal osmotic pressure of marine bacteria and halophiles was equal to, or less than, the external environment; consequently, spheroplasts of these bacteria should be stable in the growth medium Second, the media, in particular those containing sea water, are characterized not only by a high osmotic pressure but also by a high content of magnesium ions, a characteristic of solutions used to stabilize penicillin-induced spheroplasts of Gram-negative bacteria[4] The techniques for inducing spheroplasts of marine bacteria and a comparison of the osmotic fragilities of cells and spheroplasts of one species are described briefly in this communication.

The five types of bacteria used have been described recently[5], all were Gram-negative rods characterized by osmotic fragility and salt requirements for growth. The medium consisted of a tryptic digest of casein, trypticase (Baltimore Biological Laboratory, Inc), 1 per cent, dissolved in artificial sea water of the following composition sodium chloride, 0 4 *M*, magnesium chloride, 0 05 *M*; sodium sulphate, 0 01 *M*; and potassium chloride, 0·01 *M*. The experimental cultures were grown in 20-ml amounts of medium in 250-ml Erlenmeyer flasks each fitted with a side-arm tube to allow periodic measurement of turbidity. Subsequent to inoculation, as increasing turbidity indicated growth, penicillin *G* was added to the flasks. Three amounts of penicillin, to give final concentrations of 1·0, 100 and 1,000 units per ml , were tested Wet mounts of cultures were prepared hourly and examined by phase microscopy

The osmotic fragilities of cells and spheroplasts of one species (*MB* 22) were compared by determining the turbidity[6] and indole formation[7] of preparations washed in sea water and suspended in graded concentrations of sodium chloride The turbidity was measured photometrically with a Spectronic 20 The indole formed from L-tryptophan was determined by the method of Wood, Gunsalus and Umbreit[8]

Morphological alteration was observed in all species after 1 hr cultivation in the medium with 100 units of penicillin per ml , after 2 hr all cells of four of the five species had been converted to spheroplasts. The sequence of spheroplast formation was typical[4], from the initial 'rabbit ear' structure to the formation of spherical bodies having the crescent-shaped refractile area One organism, *MB* 2, did not form spheroplasts, but showed greatly enlarged and swollen 'rabbit ear' structures After 5 hr in 1 0 unit of penicillin per ml , *MB* 14 had formed spheroplasts, *MB* 22 had formed serpentine cells about ten times normal length, and the other species showed no apparent change One organism (*MB* 21), a peritrichous Gram-negative rod, was converted to spheres after 2 hr incubation with 100 units per ml. of penicillin, but examination after 5 hr. showed the culture to have returned to its rod form, possibly by virtue of an active penicillinase Motility persisted in the cultures treated with penicillin, in some cases even after the formation of spheres, but was lost in all species, with the exception of *MB* 21, after several hours.

Table 1. COMPARISON OF OSMOTIC FRAGILITIES OF CELLS AND SPHEROPLASTS OF *MB* 22

Molarity of sodium chloride in suspending fluid	Residual turbidity (per cent)*		Residual indole formation (per cent)†	
	Cells	Spheroplasts	Cells	Spheroplasts
0 0	73	17	0	0
0 1	86	83	60	40
0 2	95	95	93	47
0 3	95	95	100	93
Artificial sea water	100	100	100	100

* Percentage of optical density as compared with optical density in artificial sea water Optical density of cells in artificial sea water, 0 56, optical density of spheroplasts in artificial sea water, 0 59

† Percentage of indole formed as compared to indole produced in artificial sea water (10 6 μgm /10 min)

Comparison of the osmotic fragilities of cells and spheroplasts of *MB* 22 (Table 1) indicates that tryptophanase activity and turbidity are both dependent on the osmotic pressure of the fluid in which the cells are suspended. However, it cannot be said with certainty that the spheroplasts are more susceptible to lysis than the cells The low residual turbidity of the spheroplasts in distilled water may indicate the lack of cell wall material Microscopic observation of the distilled water lysates of spheroplasts showed only disorganized debris while cell wall ghosts were seen in similar lysates of the cells

The formation of stable spheroplasts from marine bacteria in a culture medium having an osmotic pressure equivalent to that of sea water suggests that the marine bacterium may not require the rigid cell wall to maintain its cellular integrity in the natural environment Possibly the rigid cell wall indicates the evolution of these forms from organisms adapted to more hypotonic environments, since it is in the latter circumstances that the rigid cell wall of bacteria has a selective advantage making the organism osmotically independent of its environment

Flagellar Changes in *Escherichia coli* induced by Temperature of the Environment

THE effect of change of environmental temperature on the motility of a strain of *Escherichia coli*, type I (N C T C 8196) has already been described[1] This strain, which appeared to be non-motile when examined after 18-hr growth at 37° C in meat extract broth or in the same medium solidified with agar, was found to be motile in the early stages of exponential growth (5 hr at 37° C.) and after growth for 18 hr. or longer at 20° C Storage of non-motile cells grown at 37° C at a lower temperature (20° C) for 1–2 days led to the recovery of motility by most of the cells in the culture. Cells grown at 20° C. retained motility for several weeks, but lost it rapidly when transferred to the incubator at 37° C

The effect of temperature of growth and storage on a further fifteen strains of *E coli* has since been investigated, and seven of these showed rapid loss of motility in cells grown at 37° C and long-lasting motility in cells grown at 20° C. Of the remaining eight strains some were non-motile at all growth temperatures and others developed and retained motility at growth temperatures of 15–37° C. In these seven strains, showing transient motility when grown at 37° C and long-lasting motility at lower growth temperatures, there was some variation in the recovery of motility when non-motile, flagellate cells

Table 1 EFFECT OF GROWTH TEMPERATURE ON FLAGELLA, MOTILITY AND CELL YIELD IN CULTURES OF THREE STRAINS OF *E coli* TYPE 1 GROWN FOR 24 HR IN MEAT EXTRACT BROTH

* Optimum temperature for cell growth

were stored at 20° C. The recovery of motility varied from a minimum of 1–5 per cent of the cell population to a maximum of about 80 per cent, according to the strain. This recovery of motility at lower temperatures could not be wholly accounted for by the growth of new cells, since in some strains the number of cells with recovered motility greatly exceeded the increase of population. It should be emphasized that the loss of motility at 37° C was not, in most cases, due to a loss of flagella since in six of these seven strains cells grown or stored at 37° C retained their flagella. The flagella had lost the power to propel the cell—they had become paralysed.

The influence of temperature on motility in a number of bacterial species has been described[2-5], but in the examples reported loss of motility would seem to be due to loss of flagella in cells grown at a high temperature or loss of function in already-formed flagella in cells exposed to a high temperature. Thus the rapid loss of function by flagella during growth at the optimal temperature (30–37° C) and the prolonged maintenance of function by flagella formed at lower temperatures seemed to merit further investigation.

As mentioned earlier, a total of sixteen strains of *E coli* type I were examined. They consisted of four laboratory stock cultures and twelve strains of *E coli* type I consecutively isolated in the bacteriological laboratory of the Western Infirmary, Glasgow. They possessed the following characters: lactose fermented with acid and gas, indole formed, methyl red test positive, Voges–Proskauer test negative and no growth in Koser's citrate. Motility was determined in wet films from meat extract broth cultures or from the condensate water of meat extract agar slopes. Rough estimates were made of the proportion of motile cells, the estimates being checked by a second observer. Flagella were demonstrated and counted in films stained by Leifson's stain[6] or Kirkpatrick's silver stain[7].

Out of the seven strains showing motility after 5-hr. growth at 30–37° C and loss of motility after 18-hr growth at this temperature, the first three examined were subjected to more detailed investigation. Each strain was grown in meat extract broth at temperatures ranging from 15 to 44° C. At the end of 24-hr incubation the proportion of cells showing flagella and the proportion of motile cells were determined. The amount of growth was measured turbidimetrically in the Spekker absorptiometer (previous measurements showed that the percentage of light absorbed was closely related to cell numbers). The results are shown in Table 1. The finding that the optimum temperature for demonstration of motility in 24-hr cultures may be considerably lower than the optimum temperature for cell yield confirms what most bacteriologists find. The three strains show an essentially similar pattern although they differ in regard to the optimum temperature for growth, flagella, and motility. Thus it is possible to distinguish three types of cell in each strain (*a*) non-motile, non-flagellate cells grown at elevated temperatures (above 40° C. for strain *W I G*), (*b*) non-motile, flagellate cells grown over a middle range of temperatures (23–40° C for strain *W I G*), (*c*) motile, flagellate cells grown at low temperatures (below 23° C for strain *W I G*). Another way of putting it would be to say that in the upper range of growth temperatures flagella are not produced, in the middle range they are formed, but lose activity rapidly—they become paralysed; and in the lower range flagella are formed which retain their function for 24 hr or more (strain *W I G* is still motile after storage for 3 weeks at 20° C).

An inevitable question is whether there are any differences in structure or composition between active and paralysed flagella, and the simplest approach, perhaps, is to look for antigenic differences. This was done and differences were found. Rabbits were immunized with formolized cells of the three types of strain *W I G*—non-flagellate cells grown at 43° C., flagellate, non-motile cells grown at 36° C, and flagellate, motile cells grown at 20° C. The resulting antisera showed, as one might expect, considerable cross-reactions. But, after a number of absorptions with cells heterologous in regard to growth temperature, sera specific for the homologous cells were obtained. Table 2 shows the results of experiments in which absorbed antiserum prepared against cells grown at 36° C (flagellate, non-motile) and absorbed antiserum prepared against cells grown at 20° C (flagellate and motile) were titrated against formolized '*H*' suspensions of the three types of cell listed here. That these results are due to the presence of antibodies to specific flagellar antigens is shown by our finding that the absorbed antisera did not agglutinate '*O*' suspensions or cells which had been stripped of their flagella by high-speed agitation in the M S E blender[8]. Clearly, therefore, there are antigenic differences between paralysed flagella produced by growth at elevated temperatures and active flagella formed in growth at lower temperatures.

Table 2 AGGLUTINATION OF CELLS OF STRAIN *W I G* GROWN AT 43° C, 36° C and 20° C AGAINST ANTISERA PREPARED AGAINST CELLS GROWN AT 36° C AND 20° C AND LATER ABSORBED WITH NON-HOMOLOGOUS CELLS

Agglutination tubes incubated for 4 hr. at 56° C. and 20 hr at 20° C

Cell suspension of cells grown at temperature shown (° C)	Agglutination titre as reciprocal of dilution of antiserum	
	Antiserum to 36° C. cells (absorbed by cells grown at 20° C and 43° C)	Antiserum to 20° C cells (absorbed by cells grown at 36° C and 43° C)
43	Nil	Nil
36	1,280	Nil
20	Nil	640

Summarizing, one might say that in the sixteen strains of *E coli* type I examined, seven showed the possible existence of two forms of flagella—a functional or active form produced in growth at low temperatures and a non-functional or paralysed form produced by growth at higher temperatures Conversion from one form to the other could be obtained in varying degree by switching the incubation temperature For the one strain examined serologically, these two forms differed antigenically

No simple explanation of the phenomenon occurs to us One can scarcely account for it by postulating exhaustion of nutrients or accumulation of toxic metabolites at the higher temperature, since cells which had lost motility could regain it on transfer to a lower temperature In some strains the number of cells recovering motility exceeds the number of new cells formed. Loss of motility through oxygen deficiency would seem to be ruled out by the occurrence of the phenomenon in actively aerated cultures Nor is it enough to say that high temperatures favour a flagellar structure inimical to motility since young cells are motile at elevated temperatures. One might, of course, postulate the accumulation of toxic products at higher temperatures which are subjected to further change in reactions favoured by lower temperatures, but this ignores the finding of antigenic differences A satisfactory explanation still eludes us

Free-Radical Formation during Storage of Freeze-dried *Serratia marcescens*

BACTERIA which have survived freeze-drying retain the capacity to regenerate colonies after prolonged storage under vacuum, in contrast to their rapid loss of this capacity when stored in air The question of whether bacteria stored under such conditions are dormant or whether some metabolic activity continues to maintain the bacilli in a living state is of fundamental importance to a further understanding of the physiology of life in low-moisture environments Heckly[1] has reviewed many of the problems associated with freeze-drying Results of preliminary work on freeze-dried cells had indicated a slow gaseous uptake when the material was stored in dry air and a greater uptake if stored under moistened air Because the results were not reproducible, other techniques were examined, specifically that of electron paramagnetic resonance, in the hope of finding an indirect measurement of respiration The fundamental theory and practice of electron paramagnetic resonance has been reviewed by Ingram[2], while a review of biological applications of the phenomenon has been given by Sands[3]

Serratia marcescens was grown in Bunting's[4] medium (modified, except in one instance, by withholding the iron citrate) in shake flasks at 34° C for 24 hr Cells were collected by centrifuging and resuspended in 0 066 *M*, *p*H 7 0, potassium phosphate buffer by mixing with a pipette for about 5 min The suspension was recentrifuged and again the cells were suspended in buffer fortified, except in one instance, by the addition of lactose[5] Suspensions were divided into two portions, one portion was either placed in an autoclave or treated with mercuric chloride to kill the bacilli, the other portion was untreated

Preparations were distributed, 16 ml per 60 ml Army-style vaccine bottle, shell frozen, and the bottles were placed under vacuum (ambient temperature, 24 hr , 2–5μ mercury pressure) All preparations in a given experiment were frozen and dried simultaneously The bottles were then removed to a dry-box and the dried material was transferred to either weighed glass vials or into quartz tubes suitable for electron paramagnetic resonance work Vials and tubes were then flame-sealed either under atmospheric pressure or at a pressure of less than 10μ mercury In one instance the air was replaced with water-pumped nitrogen Reconstitution of the dried material was accomplished by adding an appropriate volume of sterile distilled water to the bottles Viable cell numbers were determined by serial decimal dilution followed by surface colony counts on Bunting agar plates Colonies were counted after 24 hr incubation of the plates A Varian *V*–4500 electron paramagnetic resonance spectrometer with 100-kc /s field modulation and a 6-in magnet were used to obtain the spectra of the dried samples

Viable dried bacilli were found to exhibit a weak, single-line resonance spectrum having a *g*-value near 2, and of line-width approximately 11 gauss (peak-to-peak on derivative curves) A similar phenomenon has been reported for other dried biological samples[6] Samples sealed in air, however, showed a marked increase in the intensity of their resonance spectra with time A sample stored 90 days under vacuum produced no augmented signal, but the signal immediately showed a change in intensity when the vial was opened to the atmosphere

In Fig 1 the reciprocal of the relative intensity, as the fraction of the original signal intensity, is plotted against time and the loss of colony-forming units is plotted on the same scale The results show that the most rapid increase of the signal occurred during the first week of storage, after which the rate decreased The concentration of radicals in these samples, determined by comparison with a standard sample of known concentration, was approximately 10^{12}/mgm of sample, whereas the initial number of viable bacilli varied between 4 and 8 × 10^{9}/mgm , there were about 200 radicals formed per living bacillus An outline of experimental details and results is shown in Table 1

The vial associated with experiment 1 *b* (Table 1) was re-evacuated overnight after a fairly high number of radicals had formed, but the signal did not decrease The vial was then opened and distilled water was added to the contents Subsequent analysis failed to show the presence of a measurable free-radical content

These results may be interpreted in three ways (*a*) An easily oxidized molecule, perhaps a ring structure, may have reacted, non-enzymatically, with oxygen to form a free-radical which was stable under the low moisture conditions Scholes *et al* [7] have discussed reactions of this nature Such substances could cause the death of a cell at the moment of

Table 1. SUMMARY OF THE PREPARATION AND STORAGE OF FREEZE-DRIED *Serratia marcescens* AND THE ELECTRON PARAMAGNETIC RESONANCE SIGNALS NOTED THEREAFTER

Exp. No.	Variation of storage medium	Pre-treatment	Storage atmosphere	Percentage of immediate recovery	Electron paramagnetic resonance spectra
1*a*	Iron + lactose	autoclaved	air	zero	constant medium strength
b	Iron + lactose	none	vacuum	100	weak*
c	Iron + lactose	none	air	100	small, changing to large
2*a*	No iron, no lactose	$HgCl_2$	air	zero	weak
b	No iron, no lactose	none	vacuum	2·0	weak
c	No iron, no lactose	none	air	2·0	weak, but slightly increased after 40 days
3*a*	No iron, lactose	none	vacuum	100	weak
b	No iron, lactose	none	air	100	small, changing to large
4*a*	No iron, lactose	none	nitrogen	80	faint, no appreciable immediate change
b	No iron, lactose	none	air	80	small, changing to large

* The vial was opened to the atmosphere after 6 weeks and re-sealed. A signal then appeared.

reconstitution. (*b*) An enzyme system may have been injured or inhibited, resulting in the accumulation of a free-radical intermediate within the cell. Presumably, the injury might have caused the death of the cell, though not necessarily, because the accumulated radical could act as suggested in (*a*). In support of this suggestion, Yamazaki *et al.*[8] have shown unequivocally that radical intermediates are formed in typical enzymatic oxidations. (*c*) The relatively low number of radicals per bacillus indicates that a combined form of a transition element present in trace amounts could have been responsible for the signal analogous to (*a*).

A strong similarity appears to exist between the loss of viability and the growth of the free-radical concentration in the sense that bacilli stored under vacuum conditions, which favour high retention of viability, showed no change in radical concentration, whereas those stored under atmospheric conditions, an adverse environment, exhibited a consistent rapid increase of free-radical concentration. Furthermore, a marked change occurred in both the rate of loss of viability and the rate of increase of the radical concentration after about one week's storage (Fig. 1). Thus, a correlation is indicated between the death process and the growth of the free-radical concentration, although present results preclude the assignment of a direct cause-and-effect relationship.

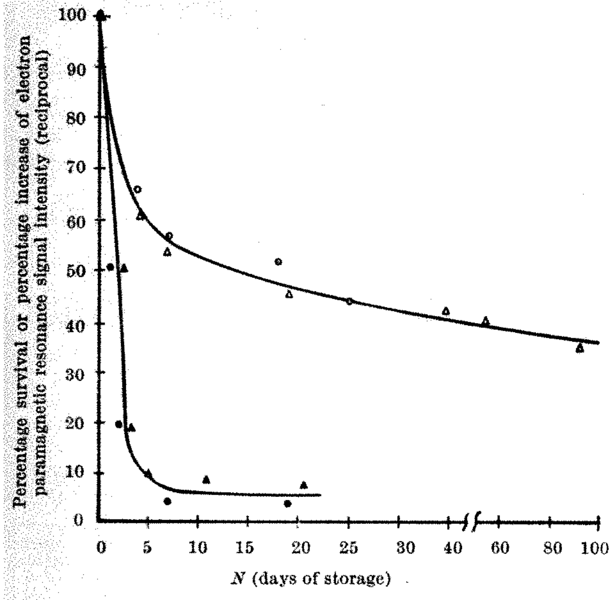

Fig. 1. Comparison of the change in electron paramagnetic resonance signal intensity with the loss of viability of *Serratia marcescens* stored in air. The points ○ and ● are for a single preparation; △ and ▲ are from different preparations.

●▲, percentage survival, $100 \times \frac{\text{No. of viable cells at } N \text{ day.}}{\text{No. of viable cells at 0 day.}}$

○△, percentage electron paramagnetic resonance intensity increase, $100 \times \frac{\text{intensity at 0 day}}{\text{intensity at } N \text{ day}}$

Both oxygen and moisture are involved in the loss of colony-forming units. Monk *et al.*[9] have shown that viability is lost most rapidly when the bacteria contain about 30 per cent moisture. Definitive data concerning this point might be forthcoming if one compared the production of free radicals to the loss of viability under varied moisture conditions, or determined whether a reduction of the free-radical content increased the apparent number of colony-forming units. The evidence suggests that some changes, perhaps metabolic in nature, occur in the dried state.

This work was sponsored by the Office of Naval Research under a contract with the University of California.

After this communication was submitted, our attention was directed to the finding by Lion *et al.*[10] that free radicals are formed during storage of freeze-dried *Escherichia coli*. This, together with our subsequent finding that similar phenomena occur when freeze-dried *Sarcina lutea* or *Micrococcus radiodurans* are tested, indicates that free-radical formation associated with the death of dried micro-organisms is generalized in nature. We take exception, however, to the suggestion that normal metabolic reactions might not be involved, because the evidence points strongly toward the oxygen-transport system as being that portion of the metabolic make-up of living structures most likely unbalanced by oxygen under dry conditions.

VIROLOGY

Serial Propagation of Types 1, 2, 3 and 4 Dengue Virus in HeLa Cells with Concomitant Cytopathic Effect

ATTEMPTS to obtain cellular destruction with dengue in stable human cell lines have thus far been unsuccessful. Banta[1] was unable to produce a specific cytopathic effect with type 1 dengue virus in HeLa cells. Beasley *et al.*[2] demonstrated replication of type 2 dengue virus on primary infection of *KB* cells, but concomitant cell damage was not observed.

It has been pointed out by Dubos and Schaedler[3], and is indeed an established clinical fact, that virus diseases often run a milder course in malnourished than in well-fed persons. There is evidence also that *in vitro* processes necessary for viral multiplication are influenced by the state of health of the cell cultures. Thus, Morgan *et al.*[4] have shown that in tissue culture, viruses remain dormant so long as the infected cells are maintained in deficient culture media, while Enders[5] has emphasized that any apparent effect of a given substance on viral multiplication may be quite indirect and related only to preservation of cell viability. Cell viability, especially in work carried out with stable cell lines, depends both on nutrients available during the growth period and on substances used in the maintenance medium following infection of cells. The latter conditions have been studied more extensively. Thus, Ginsberg *et al.*[6] introduced tryptose phosphate broth (Difco) as a supplementary beneficial factor for maintenance of HeLa cells.

I, conversely, have been interested in variation of the growth-promoting medium and the effects of this variation on subsequent viral synthesis, in particular on induction of a clear-cut, reproducible cytopathic effect. During the past five years, a standard HeLa (Gey) cell line, obtained in 1954 from the Tuskegee Institute, Alabama, has undergone more than 335 regular transfers in a growth-promoting medium containing among other ingredients 15 per cent tryptose phosphate broth. Monolayers of HeLa cells cultivated over long periods in this medium are less easily broken up by 0·25 per cent trypsin (Difco) than are those of HeLa cells grown conventionally in adult human serum and Eagle's basal medium. It is assumed, although experiments pertaining to this question have not yet been terminated conclusively, that this difference is due primarily to the ability of tryptose phosphate broth to produce a high degree of cohesion between the individual cells. Whereas non-infected HeLa tryptose phosphate broth cells show good cell viability during experimental stress periods and do not become detached easily from the tube wall, infected HeLa tryptose phosphate broth cells round up and become detached readily from glass, thus exhibiting a clear-cut cytopathic effect which is easily distinguishable at an early stage. The HeLa tryptose phosphate broth cell line has been tested experimentally since 1957 and has responded with regular cytopathic effect to the action of approximately 40 arbor viruses[7-9], including St. Louis encephalitis and Japanese *B* encephalitis, both of which gave irregular results in the hands of Scherer and Syverton[10].

In the present work, HeLa tryptose phosphate broth cells, grown in slant-type tubes in 30 per cent human serum, 10 per cent fœtal bovine serum, 45 per cent Hanks's balanced salt solution and 15 per cent tryptose phosphate broth, were washed once with Hanks's balanced salt solution, and were then inoculated with ten-fold dilutions of 10 per cent suckling mouse brain suspensions of each dengue virus: type 1 (ref. 11), Hawaiian strain, seventy-eighth passage; type 2 (ref. 12), New Guinea strain, forty-fifth mouse passage; type 3 (ref. 13), twenty-sixth mouse passage; and type 4 (ref. 13), twelfth mouse passage. Cell cultures were maintained in 97 per cent Eagle's medium and 3 per cent fœtal bovine serum, and were examined at intervals for 21 days. Careful attention was given to the *p*H of inoculated cultures, which was regulated at 7·2±0·2. Fluids were changed daily during the first week following cellular infection and thereafter three times weekly.

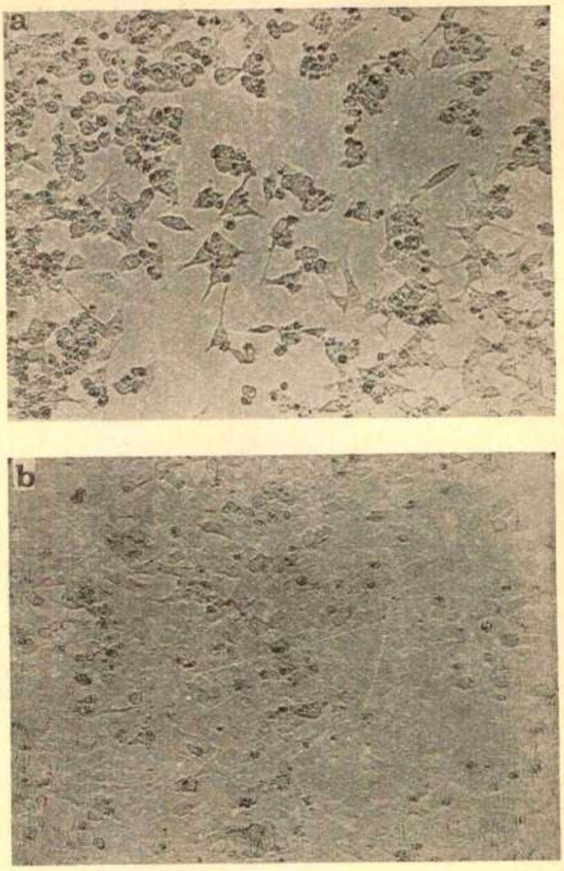

Fig. 1. Unstained HeLa cell cultures in slant-type tubes inoculated with (*a*) normal rabbit serum and type 4 dengue virus, (*b*) with anti-type 4 rabbit serum and type 4 dengue virus. (× *c*. 133)

The results (Table 1) show that the four immunologically different types of dengue virus can be propagated with concomitant cytopathic effect in HeLa tryptose phosphate broth cells. During serial tissue culture passages, carried out at 7-, 10- or 14-day intervals, TCD_{50} titres per 1 ml. ranged from 10^{-3}–10^{-6} for type 1, 10^{-4}–$10^{-6.5}$ for type 2, 10^{-3}–$10^{-6.0}$ for type 3 and $10^{-2.5}$–10^{-5} for type 4. The cytopathic effect was similar for all virus types (Fig. 1*a*) except that it was induced more rapidly by types 2 and 3. Five to seven days following inoculation of 1,000–10,000 TCD_{50}, focal lesions made up of rounded and granulated cells appeared throughout the cell sheet. These micro-plaques became more numerous and confluent during the second week post-inoculation. During the third week 50–70 per cent

of the cells had become detached from glass and disappeared into the maintenance medium, and the cells still attached to the tube wall were rounded and granulated. Only a few healthy cells, from which regeneration occurred during observation of cell cultures during 1–2 months, were present. When inoculated into 2-day-old mice by the intracerebral route, fluids of cultures exhibiting cytopathic effect proved fatal within 6–10 days. The development of cytopathic effect, similar to that described by Hotta and Evans[14,15] for types 1 and 2 dengue virus propagated in monkey kidney cell cultures, was inhibited by type-specific immune serum (Fig. 1*b*). In the *in vitro* neutralization tests, undiluted, freshly drawn[16] serum samples from immunized and normal rabbits were used.

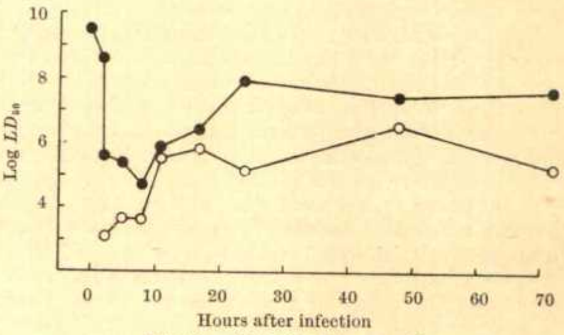
Reproduction of Tick-borne Encephalitis Virus in HeLa Cells

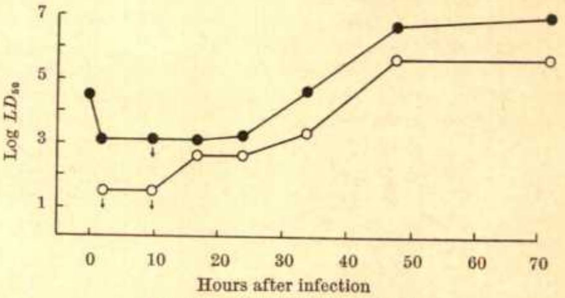
To examine the exact mechanism of reproduction of the tick-borne encephalitis virus in susceptible host cells *in vitro*, the intracellular proliferation and release of the virus into the medium have been compared with the sequence of morphological changes studied by different methods. HeLa cell monolayer cultures were used, infected with a large or a small dose of a selected variant of the Czechoslovak strain *Hypr* of tick-borne encephalitis virus[1], which is cytopathic for HeLa cells.

To ensure that materials were prepared under identical conditions for all the methods used, the contents of one Roux flask were collected for each time period, and infected cells were obtained from a homogeneous cell sheet, covering the bottom and cover-slips stuck to it by chicken plasma. Results obtained by the following methods were compared: (i) virus assessment in the cultural fluid and in cell crushes by repeated freezing and thawing; (ii) intracellular localization of virus by the fluorescent antibody method, using high-titre anti-*Hypr* horse γ-globulin conjugated with fluorescein isothiocyanate[2]; (iii) phase-contrast microscopy of living cells for cytopathic changes.

After an infection with 3,200 LD_{50} per cell, virus proliferation began between the eighth and eleventh hour after infection and reached its maximum in 24 hr. (Fig. 1). Corresponding with these results, specific fluorescence, indicating intracellular virus



Infection with 3,200 LD_{50} per cell



Infection with 1 LD_{50} per 33 cells

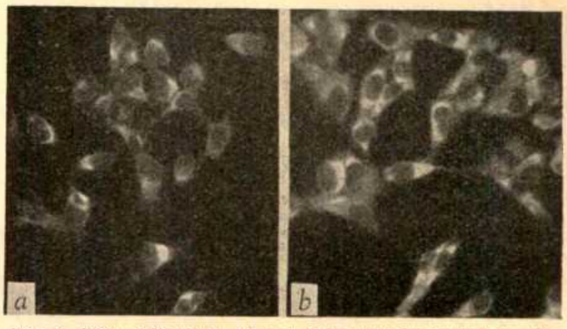

Fig. 2. HeLa cells 12 hr. (*a*) and 24 hr. (*b*) after infection with tick-borne encephalitis virus. Virus localization by fluorescent antibodies

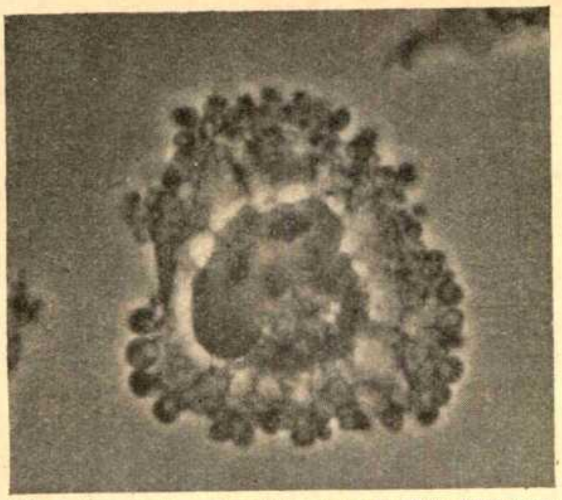

Fig. 3. Vacuolization and protrusions on cell surface of HeLa cell 24 hr. after infection with tick-borne encephalitis virus

material, was present in the majority of cells beginning with the eleventh hour after infection and intensified up to the twenty-fourth hour, starting in the paranuclear area (Fig. 2*a*) and extending later to the rest of the cytoplasm (Fig. 2*b*). At the end of the twenty-four hour period, well-marked cytopathic changes appeared in some cells, with vacuolization and protrusions on the cell surface (Fig. 3).

An infection with a small dose of virus (1 LD_{50} per 33 cells) led to the first slight increase of intracellular virus between the tenth and seventeenth hour, followed by a further increase which started with the twenty-fourth hour and reached a maximum 48 hr. after infection. The first fluorescence was rather delayed in appearance and was a maximum in not more than 50 per cent of the cells of the tissue culture. The initial cytopathic changes appeared approximately at the same time as the fluorescence.

Reproduction of other viruses of the tick-borne encephalitis complex in different cell cultures by these methods is under investigation.

Accumulation of Asparagine in Maize Plants infected by Maize Rough Dwarf Virus and its Significance in Plant Virology

It has already been shown that the rough dwarf disease of maize, so far known only from Italy, Spain and Israel, is caused by a virus[1]. Since this virus has a pronounced dwarfing effect on maize seedlings, which in most cases proves lethal, it would be expected that certain physiological abnormalities could be determined at a rather early stage of infection. The effect of this virus on the balance of free amino-acids in infected maize plants is being studied in our laboratory. During the course of this work an abnormal accumulation of asparagine was noticed in all plants bearing the virus infection symptoms, whereas in all healthy plants of the same age this amide was at the most only faintly detectable by the method of two-dimensional paper chromatography which we used[2]. Moreover, when *l*-asparagine was added to the sap extracted from diseased plants and chromatographed, its spot coincided with the one suspected to be that amide.

Later, a quick method was worked out for determining the presence of asparagine in sap of plants infected by this virus. The test is based on the distinctive orange-brown colour which asparagine gives with ninhydrin[3]. Fresh maize stalks were ground in a meat mincer; the sap squeezed through cheese cloth and then centrifuged for 10 min. at 4,000 r.p.m. For the ninhydrin test 1 ml. of the supernatant was heated for 3 min. in a boiling water-bath, diluted 10-fold in water and then filtered through Whatman No. 1 filter paper. The reaction mixture includes 0·3 ml. diluted sap solution and 1 ml. of 0·25 per cent of ninhydrin in absolute ethanol. Colour was developed by boiling in a water-bath for 2 min. followed immediately by adding 2 drops of sulphuric acid (1 : 6) and agitating the test-tube. The blue coloration disappeared in a very short time and the orange-brown coloration formed by asparagine turned yellow. The latter colour is sufficiently stable as to allow a qualitative test, although it, too, fades away slowly and therefore cannot serve as a quantitative method. It should, however, be mentioned that proline and hydroxyproline give a different heat-stable coloration on boiling with ninhydrin, but these two amino-acids did not show up on our chromatograms and therefore do not interfere in this case.

It should also be pointed out that the relative amount of sap obtained from diseased plants was noticeably higher than that from non-infected ones. This rules out the possibility of attributing the high asparagine content merely to an alleged lower water content of infected plants.

The ninhydrin test of sap was always strongly positive for all maize seedlings showing rough dwarf symptoms, whereas for healthy plants it was negative, or very seldom, weakly positive. The positive reaction, however, should not be attributed wholly to asparagine, since glycine, tyrosine, phenylalanine, histidine and tryptophan all give an orange-brown coloration with ninhydrin[3]. Part of the yellow colour obtained may perhaps be due to these and other reactions; but it is mainly due to asparagine, as was shown on our chromatograms.

The changes in free amino-acids and amides of the host plant resulting from virus infection were recently reviewed by Porter[4], who mentions at least three instances where virus infections in plants were followed by a net increase in asparagine, as compared with healthy plants. Further evidence is now available concerning at least eight more virus diseases, in which specifically asparagine is reported to accumulate in the host plant following infection. These are tobacco leaf curl virus in *Nicotiana* leaves[5], papaw mosaic and papaw leaf curl viruses in papaw leaves[6], *Ricinus* mosaic virus in castor bean leaves[7], *Luffa* yellow mosaic virus in *Luffa* leaves[7], potato spindle tuber virus[8] and potato leaf roll virus[9] in potato tubers, and finally the present record on maize rough dwarf virus. The only contradicting evidence is by Commoner and Nehari[10], who observed a deficiency in asparagine content in disks of tobacco leaves infected with tobacco mosaic virus. Since these measurements were made on leaf disks, even though floated in nutrient solution, their results cannot be safely applied to the situation in the whole plant. In fact, when the same experiments were repeated on intact plants[4], a net increase in asparagine content was evident as early as during the first 120 hr following infection

Asparagine, as well as glutamine, are known to accumulate in tissues of plants growing under unfavourable conditions, whereby proteolysis and subsequent deamination bring about an increased release of ammonia The presence of these compounds in higher concentrations in virus-infected plants should not be regarded as merely resulting from some secondary effects on the protein metabolism of the diseased plant It has already been indicated[11] that these amides are implicated—whether directly or indirectly—in the biosynthesis of purine, pyrimidine, nucleosides and nucleotides, thus bearing great significance in relation to nucleic acid metabolism, leading to the biosynthesis of the virus material itself[12] This may also offer some explanation for the specificity of the occurrence of asparagine in tissues of plants infected by viruses and for its conspicuous rareness in cases of plant diseases caused by other pathogens

GENETICS

Radiosensitive Stages in the Spermatogenesis of *Drosophila melanogaster*

THE existence of differential radiosensitivity during certain stages of spermatogenesis in *Drosophila melanogaster* was first proposed by Luning[1] Further evidence provided by Auerbach's[2] three-day brood technique suggested that the highest mutation frequency observed in the 3–6-day period following treatment indicated peak sensitivity in immediately post-meiotic stages Additional support for this view that spermatids were particularly susceptible to the mutagenic action of X-rays was derived principally from the results of irradiating immature sperm in the pupal testis[3,4] More definitive daily brood analysis[5], however, established a marked dominant lethal frequency ranging over the sixth, seventh and eighth days following the irradiation of newly emerged males, but from these results Bateman was able to draw no firm conclusion other than that this probably represented sensitive meiotic and post-meiotic stages Using the same technique, Ives[6] ascribed the first appearance of induced cross-overs on the seventh day after irradiation to the utilization in this brood of sperm treated in early meiotic and pre-meiotic stages In a similar experiment, he obtained a maximum frequency of both autosomal recessive and sex-linked recessive lethal mutations on this same day Savhagen[7] considered sex chromosome loss and non-disjunction also in parallel investigations Here again, the highest frequencies of $X0$ males were observed on those days which, by comparison with the non-disjunction experiment, probably corresponded to stages treated before anaphase I of meiosis.

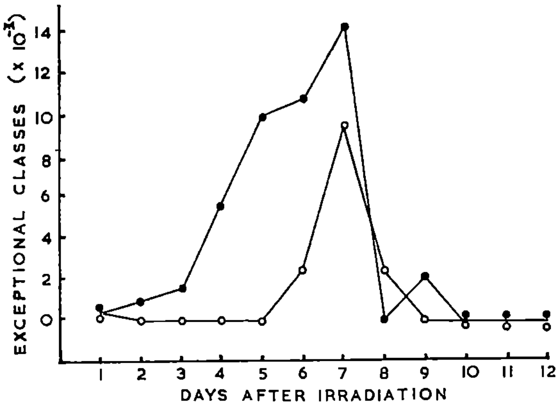

Fig 1 Brood patterns for the 12 days following irradiation ○, XXY females produced by non-disjunction in immature sperm, ●, $X0$ males produced by loss of X or Y chromosome

This communication is a preliminary account of experiments designed to detect simultaneously complete loss of X or Y chromosomes, deletion in the Y chromosome and non-disjunction between X and Y chromosomes This is achieved by means of a new, doubly marked Y chromosome stock kindly provided by Dr. D L Lindsley of Oak Ridge This Y chromosome, designated sc^8 YB^s, has the normal allele of the X chromosome marker yellow (y^+) inserted into the short arm and the dominant Bar-Stone marker (B^s) into the long arm After X-irradiation with 1,000 r , males with a wild-type X chromosome and this doubly marked Y are mated daily to three females homozygous for the X chromosome markers yellow, apricot, echinus (*y apr ec*) The normal offspring from this

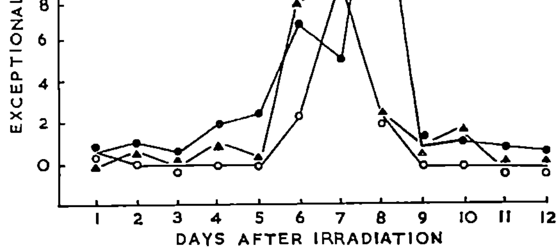

Fig 2 Brood patterns for the 12 days following irradiation ○, XXY females produced by non-disjunction in immature sperm, ●, males with B^s marker deleted, ▲, males with y^+ marker deleted

cross are wild-type (heterozygous) females and non-yellow, apricot, echinus, Bar males Complete loss of X or Y chromosomes will yield sterile $X0$ males phenotypically yellow, apricot, echinus, non-Bar Deletion of either y^+ or B^S marker from the Y chromosome will yield yellow, apricot, echinus, Bar males (abbreviated to yellow males) or non-yellow, apricot, echinus, non-Bar males (or simply non-Bar males) respectively Non-disjunction of X and Y will lead to the recovery of Bar females with XXY constitution Where possible, all exceptional flies were analysed genetically to confirm this classification

Fig 1 shows the comparative yields of $X0$ males and of non-disjunctional females while the frequencies of each deleted Y chromosome class and of non-disjunctional females are given in Fig 2 On the assumption that the determination of non-disjunction will occur only at or before anaphase in the first meiotic division, then it seems likely that the seventh brood in particular represents treated pre-meiotic stages These results also confirm the high sensitivity of meiotic and immediately pre-meiotic stages—presumably primary spermatocytes—to the mutagenic effect of X-rays

A Gene synthesizing Protease and a Pre-Viral Genome in Silkworms

ALMOST twenty years ago[1], we put forward a working hypothesis that viruses may originate in nucleoproteins in cells, and in 1943 [2] we discovered that the viral nuclear polyhedrosis of larvæ of *Bombyx mori* can be induced by a metabolite The later development of work on induction has suggested[3] that the polyhedral virus would be derived from the chromosomal segment containing the genes controlling the synthesis of protease and deoxyribonuclease We have now demonstrated that the pre-viral genome contains a gene synthesizing an alkaline protease and is located in the chromosome of healthy silkworms

Our previous investigation[4] showed that the pupa of *B mori* has no alkaline protease and never produces polyhedra without infection About 200 pupæ of the Zelem × plem strain were each injected with 0 02 ml of polyhedral solution (0 1 mgm /ml), and polyhedra were collected in the cold by our method[5] from infected individuals before death Viral particles were then isolated from the polyhedral crystals by the procedure previously described[6] and polyhedral protein from the crystals was also prepared at the same time However, the first centrifugation was carried out immediately after dissolving polyhedra in a mixture of sodium carbonate and sodium chloride, without standing overnight The proteolytic action of viral particles and polyhedral protein obtained was measured by the method previously reported[6] The results are given in Table 1, in which the protease activity is expressed in µgm tyrosine per hr produced by 10 mgm of the particles or protein

Table 1 PROTEOLYTIC ACTION OF POLYHEDRAL VIRUS

pH of reaction mixture	8 2	9 0	9 8	10 5	11 0	11 5
µgm of tyrosine: Viral particles	4	10	17	28	31	29
µgm of tyrosine: Polyhedral protein	1	3	7	13	14	12

It is thus evident that the polyhedrosis virus forms a protease which shows the highest activity at pH 10 5–11 0 As the polyhedral virus is of deoxyribonucleic acid nature and produced only in the nucleus, it can be concluded that there exists in the virus a gene which possesses the ability to synthesize the alkaline protease

Our previous experiments[5,7] have further shown that the *B mori* larva has an alkaline protease and produces polyhedra containing a protease of the same nature The white cuticle of the p_{44} strain and the black cuticle of the p^s strain respectively were taken in the midst of the final diapause, namely just at the end of the formation of new cuticle during the third ecdysis, and 0 1 gm. of the cuticle consisting of epi-, exo- and endo-cuticle was ground with 10 ml of 0 02 N sodium carbonate

These two strains were then crossed and the cuticle from the descendants in the F_1- and F_2-generations was treated with the sodium carbonate solution The proteolytic action of the suspensions obtained was immediately measured at pH 10 5 in the same way as before[6] The results are given in Table 2, in which the protease activity is expressed in µgm tyrosine produced by 10 mgm of cuticle per hr

Table 2 PROTEOLYTIC ACTION OF LARVAL CUTICLE

Generation	p_{44}	p^s	$p_{44} \times p^s - F_1$	$p_{44} \times p^s - F_2$	
Colour of cuticle	White	Black	Black	White	Black
µgm of tyrosine	81	161	183	71	181

It is thus obvious that there exists a correlation between the proteolytic activity and colour of the skin, one of the tissues in which polyhedral virus is produced As it has already been established[8] that the plain white of the p_{44}-cuticle and the striped black of the p^s-cuticle are governed by the genes in the second chromosome in the larval cell, and that the latter is the dominant, we may conclude that the gene synthesizing the alkaline protease is located in the chromosomes, possibly in the second chromosome Actually in an experiment the number of white and black larvæ in one group of the F_2-generation was 138 and 429, respectively Similar results concerning the activity of cuticular protease and the ratio of F_2 larvæ were also obtained in the case of the reciprocal cross

In view of these observations, it seems reasonable to assume that, by the inducing process, this special pre-viral genome in larval chromosomes can be activated to form the polyhedral virus

University of London (at the Wright–Fleming Institute of Microbiology, St Mary's Hospital Medical School, Norfolk Place, London, W 2), at 5 p m —Prof R Hare ' Sir Almroth Wright'' (Commemorative Lecture) *

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr I Friedmann "Electron Microscopy in Pathology of the Ear, Nose and Throat" * (Fourteenth of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 5 30 p m —Prof K R Popper "Science and the Growth of Knowledge" * (Last of four Shearman Memorial Lectures)

Royal Institute of Chemistry, London Section (joint meeting with the Battersea College of Technology Chemical Society, at the Battersea College of Technology, Battersea Park Road, London, S W 11), at 7 p m —Dr C C Hall "Chemical Aspects of the Work of the Warren Spring Laboratory"

Thursday, November 30—Friday, December 1

Institution of Electrical Engineers, Measurement and Control Section (in conjunction with the British Nuclear Energy Conference, at Savoy Place, London, W C 2)—Symposium on "Nuclear Electronics"

Friday, December 1

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Mr E B Worthington "The Science of Nature Conservation"

Saturday, December 2

Association of Agriculture, and the British Agricultural History Society (at the London School of Economics, Houghton Street, Aldwych, London, W C 2), at 11 a m —Agricultural History Conference

British Mycological Society (at the Linnean Society of London, Burlington House, Piccadilly, London, W 1), at 2 p m —Annual General Meeting, followed by Miss G M Waterhouse "The Zoospore" (Presidential Address)

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Mr W K Ford "Tropical Insect Life" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Research Assistant (male, with a degree in chemistry and interests in biochemistry), to assist in a Medical Research Council supported programme of research into dental disease—The Secretary, London Hospital Medical College, Turner Street, London, E 1 (December 2)

Assistant Lecturers or Lecturers in Experimental Psychology, Applied Mathematics, Pure Mathematics, Inorganic Chemistry, Physical Chemistry, Applied Mathematics or Statistics Mechanical Engineering, Civil Engineering, and Production Engineering—The Registrar, The University, Nottingham (December 9)

Lecturers in Materials in the Department of Engineering, to be responsible for equipping a new materials laboratory and teaching modern physical theories of material behaviour—The Registrar, The University, Leicester (December 9)

Lecturer in Social and Developmental Psychology—The Registrar, The University, Leicester (December 9)

Senior Lecturer in the Department of Biochemistry—The Registrar, The University, Leicester (December 9)

Assistant Experimental Officer (with a pass degree or equivalent qualification) in the Department of Physiology and Plant Culture, to assist in physiological studies in controlled environments —The Secretary, John Innes Institute, Bayfordbury, Hertford, Herts (December 10)

Senior Lecturer and a Lecturer in the Department of Mathematics, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 20)

Chair of Applied Physics—The Registrar, The University, Hull (December 31)

Chair of Sociology—The Registrar, The University, Hull (December 31)

Lecturer or Senior Lecturer in Genetics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 31)

Lecturer in Bacteriology in the School of Veterinary Medicine—The Registrar, Trinity College, Dublin 2 (January 1)

Chair of Theoretical and Inorganic Chemistry in Victoria University of Wellington, New Zealand—The Secretary Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, January 10)

Lecturers in Physics—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne 1 (January 15)

Lecturer or Assistant Lecturer in Zoology at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 15)

Research Officer (preferably with an honours degree in science, agriculture or forestry, and experience in research) of the Tussock Grasslands and Mountain Lands Institute—The Registrar, Lincoln College, Lincoln, New Zealand (January 15)

Chair of Engineering in the University of Malaya, Kuala Lumpur —The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Kuala Lumpur and London, January 31)

LECTURERS OR ASSISTANT LECTURERS (3) (with a special interest in organic or inorganic or physical chemistry) IN CHEMISTRY at the University College of The West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 31).

ASSISTANT EXPERIMENTAL OFFICER (with a pass degree or equivalent and experience in biological work), for work on the flow and coagulation of blood—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref 61/19

ASSISTANT LECTURER, Grade B (with a good honours degree in mathematics and preferably some teaching or research experience) IN MATHEMATICS—Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex

ASSISTANT PROFESSOR IN THE DEPARTMENT OF PHYSICS—Head, Department of Physics, Dalhousie University, Halifax, Canada

ASSISTANT PROFESSOR OF PHYSICS—Prof C E Challice, Department of Physics, University of Alberta, Calgary, Alberta, Canada

BIOLOGY GRADUATE (preferably with a knowledge of immunological technique) IN THE ENDOCRINE DEPARTMENT, to do research on gonadotrophins—The Secretary, University College Hospital Medical School, University Street, London, W C 1

LABORATORY TECHNICIAN, for a research laboratory specializing in steroid biochemistry—Dr Ludwig Kornel, Division of Endocrinology University of Alabama Medical Center, Birmingham 3, Alabama, U S A

MEDICAL ASSISTANT EDITOR (registered medical practitioner not older than 45 years) to the *British Medical Journal*—The Editor, *British Medical Journal*, B M A House, Tavistock Square, London, W C 1, marking envelope "*British Medical Journal*—Assistant Editor"

POSTDOCTORAL FELLOW IN THE DEPARTMENT OF BIOCHEMISTRY—C S Hanes, Department of Biochemistry, The University, Toronto

POSTGRADUATE RESEARCH ASSISTANT (with an honours degree or equivalent) IN PHYSICAL-ORGANIC CHEMISTRY—The Head, Chemistry Department, University of Saskatchewan, Saskatoon, Canada

RESEARCH ASSISTANT, for work on the clathration and occlusion of rare gases—Prof R M Barrer, Chemistry Department, Imperial College of Science and Technology, London, S W 7

RESEARCH ASSISTANT IN THE DEPARTMENT OF PATHOLOGY, for tissue culture work on the nervous system—The Professor of Pathology, School of Medicine, The University, Leeds 2

RESEARCH ASSISTANT (with a degree or H N C in electrical engineering or applied physics, or an equivalent qualification, and preferably some experience in electronics and/or vacuum techniques), for work on the High Voltage Electron Microscopic project—The Secretary, Department of Physics, Cavendish Laboratory, Free School Lane, Cambridge

SENIOR LECTURER (graduate of a British university) IN BIOCHEMISTRY—Clerk to the Governing Body, Battersea College of Technology, London, S W 11

TECHNICIAN IN BIOCHEMISTRY (A I M L T , B Sc , or A R I C)—The Director, Department of Pathology, Paddington General Hospital, London, W 9

CO-OPERATION IN RESEARCH

IT is something more than mere coincidence that Dr B V Bowden, in a discourse at the British Association at Norwich last September on the impact of automation, should have urged not simply the wider and more imaginative use of the electronic computer but also pointed to the implications of such developments for university and technological education In fact, the position of the universities in this field has been the subject of special comment in the general survey from the University Grants Committee which this year accompanies the usual returns from universities and university colleges in receipt of a Treasury grant Furthermore, in the June 1961 issue of *Vestes*, the Australian universities review, J M Bennett describes the university computing centre in Australia, where three such centres have been operating since 1956 Again, the current issue of *Impact* includes a paper by Prof R Courant which, while discussing general problems confronting computing centres, emphasizes particularly the major effort required, especially in universities, to train a generation of scientists eager and competent to make full use of computers as scientific tools—an effort which requires the breaking down of departmental boundary lines and as such may involve changes in departmental organization, as well as co-operation on a broad scale with industrial research organizations A recent article by Dr R C Campbell in *Chemistry and Industry* (p 1786, November 4), on the administrative uses of a computer in a university, points to some interesting possibilities in the use of computers and indicates an encouraging prospect for such developments

Mr Bennett, who notes that more than 3,000 automatic digital computers are now in service throughout the world and that more than 100 are in service in universities in the United States, while nine British universities have computing centres, considers not merely the man-power required to operate computers and to utilize them, but equally the problems of finance and administration The university computing centres in the United Kingdom are financed largely from public funds through the University Grants Committee as a result of an agreement reached with the Treasury in 1954 Grants amounting to £381,000, out of the total university expenditure of £417,000, were eventually made for the purchase of computers and ancillary equipment on the recommendation of the University Grants Committee, advised by the Advisory Committee on High-Speed Calculating Machines of the Department of Scientific and Industrial Research The initial allocation was primarily on a regional basis At that time, Cambridge already possessed a computer and Sheffield was able to make very favourable arrangements for hiring computer time Accordingly, Durham, Leeds, London, Manchester, Oxford, Southampton and Glasgow received computers, and eventually Liverpool purchased a computer, partly from industrial contributions and partly from its own resources

In 1957, an Inter-University Committee on Computing was established, under the chairmanship first of Prof D R Hartree and later of Sir Willis Jackson to advise the Committee of Vice-Chancellors and Principals on policy questions and to promote co-operation in this field between the user universities and between universities and other bodies In 1959 this Committee, in its first report, emphasized the rapid expansion of university work, which had been under-estimated and was steadily squeezing out extra-mural work, and recommended further extension of computing facilities in the universities As a result, the University Grants Committee agreed, in October 1959, to consider a further allocation of computers to the universities in Britain When approached, twenty-two universities, including all but one of the universities already possessing a computer, replied that they wished to apply for a new machine

Two universities applied for *Atlas* computers and the University Grants Committee took the view that provision of machines costing £1 5–£3 million each was a question to be handled on a national basis, and accordingly the claims of these two universities and of other institutions for *Atlas* facilities have been assessed by a working party under the Minister for Science As a result of this survey, the Government has placed an order for such a computer to be installed at Harwell under the auspices of the National Institute for Research in Nuclear Science, and it is assumed that these facilities will be available to those universities which need them The University of Manchester, by its own special arrangement with the makers, will possess an *Atlas* computer which will be available to certain other universities

As regards the medium-sized computers, the University Grants Committee appointed a small sub-committee, under the chairmanship of Sir Willis Jackson, to give detailed consideration of the types of machine required by the universities, to questions of timing and priorities, and to the use that might be made of the older displaced machines This sub-committee included representatives of the Department of Scientific and Industrial Research and the Ministry of Education, and had the assistance of Dr Howlett, of the Computing Department of the Atomic Energy Research Establishment, its advice was accepted by the University Grants Committee, which in March 1961 sought authority from the Chancellor of the Exchequer for a programme to provide medium-sized computers, involving expenditure of about £2 million, between 1961 and 1965 This authority has been given, and accordingly twenty-one universities are expected to have their own computer facilities, while the remaining universities have access to others

This, however, is only a particular aspect of the relations between the universities and the Government in Britain, or indeed of university expenditure on research, but it is of special interest in view of Lord Hailsham's remarks about those relations in his recent addresses on science and government in a free society (see *Nature*, November 4, p. 393, and p. 787 of this issue). Lord Hailsham did not suggest that the British system, which, in effect, allows Government funds to be administered by the universities themselves, is the only possible way of ensuring adequate Government support for university research without infringing academic freedom, but he did claim that the system works, and his addresses make very plain the dangers which attend the creation of separate Government-sponsored institutes and generally the separation of research and teaching. He was emphatic that the most advanced scientific work should be located in or near the universities, where this is possible, or directed by university personnel.

In his earlier address, Lord Hailsham was concerned with maintaining a healthy balance between research and teaching, between Government research and that proceeding in the universities and in industry, between pure and applied research and development work, and he was no less conscious of the growing opportunities for international co-operation in research. It is with the balance between research and teaching that the University Grants Committee is concerned, and at the request of the Advisory Council on Scientific Policy it has made a further estimate of the resources in the universities which are devoted to research in the pure and applied sciences, medicine, dentistry, agriculture, forestry and veterinary science. Although it wishes to have further information of the numbers of technicians engaged in the various departments in the universities, since this matter, which has an important bearing on the effective use of research workers, is one to which the Committee is paying special attention in assessing the financial needs of the universities for the next quinquennium, the results of this survey are given in the Committee's general survey attached to the latest *Returns**.

The survey covered 16,882 university staff and research students, of whom 53 per cent were in the pure sciences (mainly physical) and 19 per cent in the applied sciences. Medicine (3,324), chemistry (3,013), engineering (2,445) and physics (1,909) claimed the largest numbers. Of the total, 7,522 were research students, and the proportion of research students to university staff varied from 2·0 : 1 in chemistry to 0·2 : 1 in medicine and dentistry. About 49 per cent of the time of staff and research students is estimated as devoted to research, varying from as little as 21 per cent in dentistry to 57 per cent in zoology. The total of 8,534 technicians included 563 chief technicians, 1,365 senior technicians, and 2,475 technicians, and on an average, there was one technician per member of staff and one to 1·8 members of staff and research students, the ratio varying greatly between subjects. Many of the technicians, moreover, had duties connected with teaching as well as with research, and a comparison with the figure for research laboratories in other institutions suggests that the ratio of technicians to research workers in the universities in Britain is below that necessary to ensure that the time of research workers is used most economically.

The University Grants Committee may well be understating the need, but it is satisfactory to note that it proposes to give special attention to this factor in its current assessment of the needs of the universities. On the expenditure side, the survey estimates that of departmental expenditure totalling £28·3 million, and including academic salaries, wages, departmental and laboratory maintenance and other like items, £14·1 million is attributable to research. If, further, it is assumed that some two-thirds of such 'overhead' expenditure as administration, libraries, maintenance of premises and the like applies to the sciences and applied sciences, and half of this two-thirds is attributed to research, the total rises to £18·3 million. To make this figure comparable with the total of £22 million quoted for the year 1958–59 by the Advisory Council on Scientific Policy in its report for 1959–60, there must be added a proportion for non-recurrent grants for building and equipment. For 1959–60 these grants amounted to £4·2 million, and if account is taken also of awards to research students which do not pass through the university accounts—and these are assumed to be worth on average £470 a year each—a further £3·4 million should be added, bringing the total to £25·9 million, which would represent some £2,140 for each research worker per annum, departmental expenditure alone amounting to £1,666, of which about £865 represents salaries of university staff. It is not clear, however, whether the figure of £25·9 million includes all the sums for research at universities which are made available through the Council for Scientific and Industrial Research and the Research Councils, but the figure compares with £23·3 million for research and development carried out by the universities quoted by the Advisory Council on Scientific Policy in the current report. Sir Harry Melville put the contribution from the Department of Scientific and Industrial Research in research grants and post-graduate studentships at more than £2·5 million in the past financial year.

The distribution of this research effort in the different groups of sciences varies from 38·3 per cent of man-power and 32·8 per cent of expenditure in the physical sciences to 1·8 per cent of man-power and 1·7 per cent of expenditure in dentistry; for the biological sciences the corresponding figures are 9·8 and 10·0, for the applied sciences, 19·1 and 18·0, for medicine, 19·7 and 27·2, and for agriculture, forestry and veterinary science, 5·9 and 6·6.

The University Grants Committee quite rightly once again urges that too great a significance should not be attached to many of the differences in research effort between subjects. Obviously, some regard must be had to personal idiosyncrasies and abilities, and the research effort made in any one subject will undoubtedly vary from time to time, depending on such factors as the presence of an outstanding worker in a subject and the level of interest In fact, the interest now being taken in the balance of research effort in Britain arises essentially from two roots the need to see that in the universities and elsewhere the resources at the disposal of the research worker are such that he can make effective use of his time and of the costly equipment that is now so often required, and secondly, to ensure that there is a reasonable balance of research effort between the universities and other research institutions, Government or independent, between pure and applied research and development, as well as between subjects It is only on such a basis that it is possible to plan a reasonable allocation of the limited resources in Great Britain and to press the claims of a particular research effort in the face of conflicting claims

---

* University Grants Committee. Returns from Universities and University Colleges in receipt of Treasury Grant, Academic Year 1959–60. Pp. 76. (Cmnd. 1489.) (London: H.M.S.O., 1961.) 4s. 6d. net.

Lord Hailsham's recent addresses show that he is well aware of the problems involved. and alive to the dangers either of parsimony or of interfering with the universities' choice of projects or disposition of their resources Inevitably, co-operation involves compromise and adjustment as between universities and other institutions, or between Government departments, industry and the universities, and the development of university co-operation in the use of computers, radio telescopes and cyclotrons, quite apart from the growth of international co-operation in research, will accentuate the need for further collaboration. At the present moment, when the University Grants Committee is formulating its proposals for the next quinquennium under the shadow of the Chancellor of the Exchequer's call for economy and reduction in public expenditure, a heavy responsibility rests on the Minister for Science to see that there is no retraction of the universities' research effort, either in respect of its contribution to the advancement of knowledge or to the training of man-power for research The University Grants Committee, from its general review, appears to be taking the right measures to ensure the elimination of waste and the effective disposition of whatever resources may be made available It is for the Minister for Science to satisfy himself that the resources put at the disposal of the universities are indeed adequate for the purpose, having regard to the nation's need for trained man-power, its total research effort in industry and Government institutions as well as in the independent research institutions, and to the possibilities of co-operation both on the national and on the international scale In that task, moreover, he should derive powerful support from the recent report of Lord Plowden's committee in opposing any policy that would tend to apply 'start and stop' to research projects Lastly, in a time of financial stringency, the Minister for Science might be specially watchful to see that no measures are introduced which hinder that invaluable movement and interchange of personnel between institutions or the regular exchange of ideas on which he himself has rightly placed much stress

RESEARCH IN THE UNIVERSITIES*

By The Right Hon. VISCOUNT HAILSHAM, P.C.

Lord President of Council and Minister for Science

THE Rector of Imperial College has reminded me that it is a hundred years since the death of its founder, the Prince Consort, a man of vision and prescience who saw clearly, in an age only partially awakened to such things, the revolutionary changes for good which might be made in the conditions of human life by an unfolding scientific technology, imaginatively applied in a spirit of serious good will In the bright light of mid-Victorian optimism, of which Prince Albert was in part an example and in part an initiator, much that has happened since would have seemed a perversion of those eager hopes But enough has taken place to make sure that they were not altogether misplaced and to give us confidence that in their future realization the College which he founded will continue to play a noble part

When writing of the first professorial unit in the College, Prince Albert described this part as having raised the new College to "a high pitch of usefulness and popularity". Usefulness and popularity are not always co-existent, but they are no bad things, provided they are kept in just the right balance with one another, and this, I believe, is what Imperial College has done.

The Rector also suggested to me, as a main topic for discussion, the subject of research in the universities—a theme particularly suitable in view of the strong tradition of research in Imperial College, and the important part which this tradition plays not only within the College but also in the scientific, technological and industrial life of the country as a whole

This subject contains a clue to the whole development of an integrated modern culture on one hand, and of an adequate technology on the other, at the same time it is, as I shall seek to show, a matter of extreme complexity on which we have not yet discovered all the answers.

Can we begin without some idea of the kind of thing we want our universities to be, and the kind of purposes we want them to serve ? For myself I cannot, and at the risk of exceeding my mandate I must deliver my testament of faith on this topic

The eternal struggle of humanity is to reconcile freedom with authority, individual self-expression with the requirements of society There have been many definitions of freedom, ranging from national independence to freedom of worship, from universal suffrage to full employment, from social security to private enterprise As a lawyer, as a politician, as a moralist, I have discussed them all, and admit that all have a certain contingent value As a philosopher I have found them all inadequate None of them by itself is intellectually satisfying

---

* Substance of the Commemoration Day Address at the Imperial College of Science and Technology, delivered in the Royal Albert Hall, London, on October 26

I suspect that one reason for this is that, whatever it means, freedom cannot be seen in isolation from the search for the just and the true, the beautiful and the good—the ultimate values which men place on their existence In their origins in the ancient world, the universities were the places where this search was correlated and discussed, and the academic freedom of the universities themselves, their intellectual stature, their moral quality, seem to me to be matters of immense importance, theoretical not less than practical, in the discussion of the relative values of tyranny and freedom, of democracy and authority, of law and morality But if this is so, it is at least surprising that this is a matter which is almost never mentioned by the political theorists and lawyers who indulge in most of the arguments

But if a unity of purpose, an integrated understanding of man and his environment is not to be found in the universities, it will not be found in the nation, or in the world This is dimly apprehended even by the multitude, even by the popular press when they pay sometimes disproportionate attention to the strange actions of undergraduates—or to the even stranger opinions of professors But in terms it is almost never said Yet the university world is the true melting-pot of society, the one great mixer where class distinctions are being abolished before our eyes, the one aristocracy of merit divorced from privilege, the one democracy where equality of opportunity is not confused with equality of achievement, reward or esteem. In the humanities it is generally accepted that, at this level, teaching and research cannot wholly be separated My thesis to-day is that teaching and research in science must similarly be allied

Yet side by side with their function as the teachers of human society as a whole, the universities have also the task of providing vocational training It is idle to disregard or minimize this aspect of their activities —although many academics are far too fastidious to speak of it openly, and sometimes write letters to the papers decrying its discussion The ugly truth is that if it had not been for this function, the universities would have neither been brought into being nor survived If the Church had not needed educated priests, if the State had not needed educated administrators, if industry had not needed educated executives and technologists, there would have been no universities, and although medicine and law and the engineering professions, at least in Great Britain have contrived partly independent systems, I doubt myself whether even these would survive—or maintain adequate standards—without a parallel system of academic courses to give them intellectual body

But the truth is that the two functions are not independent of one another Even on the vocational plane, teaching of the order we require for our administrative, our scientific and industrial leaders cannot be wholly divorced from research—the true pioneering of knowledge of all kinds Research will tend to become barren and research workers to die out if attempts are made to divorce it from teaching

But how is research to be financed? Who is to call the tune? And if the tune is to be called by the spirit of research itself, the λόγος as Plato puts it, carrying us along like the wind, What conceivable motive will be his who pays the piper ?

The issue of academic freedom has never been very far below the surface of political life At the time of the Reformation, and the Civil War, the questions were obvious But in recent years, and certainly until 1939, they were scarcely asked No one grudged the Prime Minister the right to nominate Regius professors, and academic resources depended as much on fees, endowments and donations as on public funds

But by 1946 it was apparent that the scale of expansion forced on the universities by the range and rapid development of modern knowledge, and the insatiable appetite of industrial society for trained graduates, made it necessary that from henceforth the main patron of the universities would be the State Happily to hand was the appointed instrument of State and university—the University Grants Committee, brought into being in 1919 I would think that on the whole this has managed to the general satisfaction to administer public generosity without corrupting academic freedom

In one direction, however, the University Grants Committee has required supplementation Built into university life is an innate conservatism—no bad quality, this, but one that needs to be balanced From their start, the Research Councils—by which I mean the Department of Scientific and Industrial Research, the Medical Research Council, the Agricultural Research Council, and the Nature Conservancy —have encouraged the initiation of new projects of research, and particularly in relation to medical research have founded whole teams of research workers within, but not necessarily as integral parts of, the universities and in the past four years the total value of the research grants given to universities each year by the largest of these patrons—the Department of Scientific and Industrial Research—has increased three-fold I am rather proud that this has happened entirely within my own periods of office, since I regard the development as wholly to the good

For a second function of the universities—to initiate new studies, to fill in gaps in the old, needs (as no one knew better than Prince Albert) a living patron, something more adventurous, and perhaps a little more selective, than in the nature of things the University Grants Committee can be expected to be The present size of the Government-sponsored research in the universities is, however, such as to give rise to new questions—both for the Research Councils and I would say, also for the universities—which it will be my business and that of my successors in office to investigate in the coming months and years Speaking broadly, it will be necessary to keep in mind the respective functions of the University Grants Committee and the Research Councils But, at this stage, I would only mention, in passing, two small points

First, the permanent structure of the universities is clearly a matter for the universities themselves, and the University Grants Committee is the constitutional channel for Government funds It is vital to remember that the Research Councils' function is not to finance science in the universities as a whole, but to provide funds for new developments in research which cannot be adequately dealt with within the framework of the quinquennial system But at what stage, and by what mechanism, can work originally fostered by the Research Councils be handed over—and how is the hand-over to be reconciled with the academic law of the Medes and Persians against ear-marked grants ?

Secondly, a similar question, though not entirely limited to research, arises in relation to laboratory technicians and assistants—whose activities form an indispensable part of virtually all scientific work in universities It is not my function, or that of the Research Councils, to provide part of the permanent staff of universities The University Grants Committee rightly adheres to its policy of refusing ear-marked grants This is a minor problem and can be solved within the university framework

Since I first assumed Ministerial responsibility for the Research Councils, university research has been affected by a number of changes—changes both in scale and in character—in the field of scientific research generally For one thing, in an increasingly wide range of disciplines the tools of research have become machines—and machines each of which is a major engineering project constituting a significant item in the capital investment programme Apart from the big machines, the accelerators, the Jodrell Banks, the gas-bubble chambers, there is the problem of the new institutions, sometimes clustering around the facilities of a parent body, like the National Institute for Research in Nuclear Science round Harwell, yet half resenting and half resented by the parent organization which gave it birth

Closely related to the machines, but potentially larger still, are newly emerging fields of investigation, too big, almost from the first, for association with teaching universities, too big, almost from the first, for purely national budgets, often, like space research or the *Mohole*, requiring immense vehicles and immense organization for their initiation; sometimes like CERN at Geneva, or *Dragon* at Winfrith Heath, involving international funds and wide implications in the field of foreign policy Already a large number of international organizations, some bilateral, some regional, occasionally world-wide, some for research, others involving development, have sprung into being and require careful finance and clear thinking if they are to develop on the right lines Clearly all these changes raise important implications for the relationship of universities to research, of universities to Government, and of universities to one another

One such implication that is gradually becoming clear is that in certain branches of science it is impossible for every university to have equal treatment from the Government in all spheres Ten linear accelerators each costing £1,000,000 will not make up for the absence of one linear accelerator costing £10,000,000—if one is needed, and it is quite clear that not every university can hope to have a £10-million accelerator In Britain, at any rate for the time being, there can only be one Jodrell Bank, one *Nimrod*, there can only be a few gas-bubble chambers, and only a few research reactors Where are these to be placed ? Who is to run them ? Who is to arrange their research programmes ?

When a number of such various projects are proposed by scientific enthusiasts, How are we to judge which to accept, particularly where these belong to different fields ? How are we to correlate the work of the National Institute for Research in Nuclear Science with the applications to the Department of Scientific and Industrial Research in the field of nuclear and high-energy physics—or with the budget of CERN in which we have only a minority vote ? How are the differing projects for radio astronomy to rank between one another or with the applications for big machines in other fields? How is either to rank with space research—another subject in which other countries are involved ? Can individual universities form partnerships or consortia ? Or should they all be provided for through a national extramural institution like the National Institute for Research in Nuclear Science ? If the latter, where is the facility to be placed—inconveniently for all universities, or conveniently for only one or two ? If a facility is given to one university, should any—and if so what—conditions be exacted for the benefit of the others ? If a facility depends on a particular man, what happens if he dies or resigns to move elsewhere ?

All these questions have actually arisen in a concrete form since I took office Some I have had to decide Some have been decided, with my approval, by the Research Councils We are getting a certain amount of case-law and empirical wisdom about all this But have we got it right ? This is something we shall have to discuss

But it is not only a question of big expensive machines that can be located in or near only some of the universities Somewhat similar problems arise out of the increasing diversification of subject-matter How far is it necessary or desirable, for example, to preserve the existing situation in which the scope for postgraduate work by students of a given institution is often limited by the extent of the facilities—either natural or artificial—which that institution happens by tradition or by accident to have in its possession or in its close neighbourhood ? Clearly, university statutes were—or should be—made for the needs of learning, and not the needs of learning for the requirements of university statutes Should university research still be limited in range by the migratory habit of medieval monks ? Should the availability of freshwater biology as a subject for research in Cambridge or Leeds be dependent on the contents of the Cam, or of the local Yorkshire factory effluent ? Should the availability of the Ph D to the staff of a Government research station depend on the place where each received his first degree ?

All these questions need public discussion Government may have views, but in many cases it will be the vice-chancellors, the courts and senates, the faculties and the colleges, which supply the answers

What is to be the relationship between courses of study and research in the universities and the known requirements of industry ? Distinguished academics often write to *The Times* expressing disquiet at the tendency of industry to demand courses from universities in fields which are remote from traditional fields and are of deliberate relevance to practical life—for example, management studies Similar questions are asked in relation to industrial research and in some of the applied social sciences Is industrial money corrupting, as the author of one letter appeared to think ? If so, ought we not to think the same of Government money ? With due respect to the University Grants Committee, and to the Research Councils, the Government is not fundamentally so disinterested as it pretends Nor perhaps are even academics quite so pure Nearly three-quarters of Government money going into scientific research goes on the defence budget More of this than many people think is spent in the universities—and none of it could be spent at all without research workers, such as those who are trained in the Imperial College of Science and Technology

My own view is that in Great Britain we should welcome and encourage industrial money, if only as a desirable and necessary counterbalance to Government money At least it is not motivated by war or the fear of it. Moreover, there is no academic doctrine more powerful than the motto of the Royal Society "*Nullius in Verba*". When I am asked, as I sometimes am, whether it is not degrading that people should be asking for private donations towards cancer research, because the Government ought to bear the cost, I reply that I would not sleep easy in my bed if I thought that either I or the Medical Research Council were the only source of wisdom to decide which men and what ideas were worthy of support The Americans may go a great deal too far academically in their dependence on private munificence, educationally they suffer enormously from the fact that their schools and universities are in no sense a Federal Government concern But I think we may go too far the other way From my point of view the degree courses available in British universities are too narrow in scope, and some of them are orientated too academically I believe the same to be true to some extent of research work

There is another important aspect to this. One of the most important subjects with which I am called on to deal is the relative failure of British industry to make use of science and the scientist I will not bore you with figures, they are easily available. But, so far as I am concerned, the broad truth is that, outside a few main industries, far too few scientists are employed, and if more were employed some directors might not—in their present frame of mind—know what use to make of them. Not unnaturally, members of Parliament and others ask me what can be done to improve the situation Whatever the immediate answer, I am quite certain that the only radical cure lies in the universities, in a closer contact with industry, both education-wise and research-wise Contact between intelligent and right-minded people is not corrupting; almost invariably it is stimulating, and in my view at any rate academics have almost as much to learn from contact with industry as industry has to learn from the academics Certainly, contact is the only way in which either will learn anything from the other There is a great contrast between the extent of mutual regard and contact between academics and industrialists in Germany, which I have recently visited, and Britain In my view, neither gains here by the degree of apartheid it practices and, incidentally, if that apartheid were broken down, both in teaching and research, my own opinion is that the human sciences, which are excessively neglected in Britain, would also come into their own—both in the field of postgraduate research and in the field of new schools and faculties

I realize that in making these remarks in the Imperial College I am rather preaching to the converted The College's annual reports provide plenty of evidence of strong ties with industry, and of wise generosity by industry in financing work here on a variety of research projects, and there are also such things as the vacation training schemes by which students can gain valuable industrial experience

But is this enough ? Certainly in Germany you get co-operation between universities and industry to a much greater extent To take only two examples in Germany there are far fewer obstacles than exist in Britain to the combining of teaching with management or research in industry, and indeed, you get industrial concerns operating research institutes inside technological universities I know, of course, that much can be said in support of the British attitude, the ideological division between teaching and production, but need we take it quite as far as we do ? I shall not be so rash as to attempt an answer, but I feel it my duty to pose the question When we see the close contact, amounting almost to organic unity, which exists between industry and universities on the Continent, and when we see some of the results in terms of design, production, and sales on one hand, and vigorous high-grade academic development on the other, we must surely ask ourselves whether the system adopted on the Continent does not possess certain competitive advantages which Britain lacks I have spoken of the apartheid which seems to exist in Britain between universities and large sections of industry, may this not be due largely to the mere accident that many of our industries grew up outside the ambit of scientific and technological studies, and should we not see whether ways cannot now be found of bringing them together ?

There can be no easy or single way of doing this But one important need is the creation of the kind of climate of opinion in which industry and the universities turn towards each other quite naturally, and cross the gulf which has too often divided them hitherto

Every one who at some stage or other in his career goes into industry, whether in industrial research or in production or general management, and every one who goes into Government scientific establishments or public administration, will not only be helping to bridge the gulf, he will also be able to spread among others the habit and the desire of making and maintaining the closest contacts with university teaching and university research Similarly, those who remain within the university cannot unreasonably be asked to remember always the valuable help that those in the universities and those in industry can give to each other

I must stress that it is not just a matter of doing well the research that comes to be tackled, or making use of the results of research when it is done, it is a question of research-mindedness, at all points· and here we come back to the very nature of the actual courses which the universities provide Do they impart, along with knowledge, and skill in using knowledge, an adequate appreciation of the role of research, of the techniques of doing it, and of the importance of a readiness and a right way to apply its results ? I ask this not only as regards postgraduate courses, where one ought to be able to hope confidently for an affirmative answer, but even more importantly as respects first-degree courses Have the men who go out into industry straight after taking their first degrees—who after all comprise the main army of scientists and technologists—have they acquired, during their undergraduate training, a sufficient understanding—I will not say of research and of development—but even of design ? Are they carrying a lighted flame—a torch with a battery—or just a reflector ?

I do not need to labour the point and let me make clear that in directing attention, as one particular topic that I feel needs special notice, to this question of contact in research between science and industry, I must in no way be taken as ignoring the importance of the more pure, more cloistered, more fundamental research that must also go on continuously if the well-springs of our science and technology are not to dry up These are fundamental to the whole conception of scholarship—whether in the arts, or the natural sciences In the long run it will be found that the whole future of our civilization depends on the insights—I cannot refrain from calling them the artistic and creative imaginations—of a relatively small handful of men of genius, the true frontiersmen of knowledge.

I have posed a number of questions—and attempted few answers Even some of the questions may be wrongly based—or wrongly put. But I hope at least that they will be food for thought—and I hope also that the course of development in our universities and colleges of advanced technology during the coming years will be such that the answers to these questions become increasingly reassuring.

I find myself at the end attempting to formulate a few general truths which seem to me to emerge from this discussion and from the wider experience which I have gained in the past four years

If the general rule must be that research and university teaching cannot be divorced, the wider development of the subject implies inevitably closer contact between universities and Government research installations of one sort and another, between these and industry, between industries and universities, between universities and one another, between universities and places of research outside the general pattern which cannot conveniently be placed inside teaching institutions, between the scientific body within one national group and others of the same group—even between scientists of opposing groups of nations These are not really rival conceptions for the organization of research, their rules are complementary rather than exclusive, and they are in truth part of a single complex, of a constantly developing conception of a scientific life gradually transforming the body of human society as we know it

But, at the end of the day, if I am pressed with the familiar question of the egg and the chicken, if I am asked to define the point at which new growth is to be inserted into the scientific life of which I speak, I look, on one side, to the universities to provide the new ideas, but I accept the responsibility of Government to supply the initiative and the drive to convert these new ideas into actuality. The more I think of the problem confronting me as Minister for Science, the more I am convinced that the clue to the enigma lies in the universities and the colleges of technology, and where better to seek the answer to the riddle than at the Imperial College, which is in a sense both, and at a commemoration festival—an occasion when many are gathered together from both inside and outside the academic circle, many who are, many who have been, and many who will become leaders of thought in State, industry and learning

The founders of the Imperial College, of course, visualized it as a centre of learning for a more or less centralized empire Already that conception has given rise to that of a commonwealth of free and independent nations But, speaking for myself, I see the centres of learning as something more than this These are the true centres of culture in a nation By improving these we take the shortest—indeed the only practical—course towards raising the standard of knowledge and civilization of the world.

MEDICAL RESEARCH AND THE NATIONAL INSTITUTES OF HEALTH, BETHESDA, MARYLAND*

By Dr. CARL R BREWER

Chief of the Research Grants Branch, Division of General Medical Sciences

THE National Institutes of Health, which began in 1887 as a one-room laboratory on Staten Island, New York, to-day comprised forty-two buildings occupying ninety acres of land in Bethesda, Maryland, north-west of Washington, D C

To understand the role of the National Institutes in health research, it is necessary to understand that the United States is one of the most health-conscious countries in the world, and that the American people have repeatedly expressed, through their representatives in the Congress, their fervent desire to wipe out disease and the crippling effects of disease and to help themselves and other nations to a new level of healthful well-being, and to longer and more productive lives

That such goals always have been an integral part of the American philosophy is illustrated by the fact that the U S Public Health Service was established in 1798, that is, 163 years ago That such goals run as a theme through all Departments of the U S Federal Government to-day is illustrated by the fact that several of these major Departments themselves also support biomedical research, in addition to the work done at the National Institutes of Health as a part of the Public Health Service and the Department of Health, Education, and Welfare

The object is to give man a better life through research in medicine, by which is meant the medical sciences, the many portions of the biological sciences related to medicine, and those portions of the physical sciences related to medicine

I will not go into the statistics related to the monetary size of these efforts Figures on the numbers of dollars lack meaning in themselves The dollars are simply the means to the ends of action and results in research—and action and results are what we are after To help illustrate the point that the American people whole-heartedly are supporting the drive for better health, the percentage growth in the past twenty years is worth mentioning

Since about 1940, total expenditures for medical research in the United States (that is, including the moneys of private foundations as well as the Federal Government) have increased more than 1,500 times To-day, the Federal Government is supporting roughly 55 per cent of all medical research in the country, and the National Institutes of Health are responsible for about 75 per cent of the Federal Government expenditures

Thus, the National Institutes of Health form the largest biomedical research institution in the United States, and probably the largest in the world There are about 2,000 research scientists and approximately 6,000 administrators, laboratory technicians and other employees working at the various departments in Bethesda, Maryland. The total programmes of the Institutes are divided between the 'intramural' activities carried out at Bethesda and the 'extramural' activities under which the organization provides grants-in-aid support for biomedical research in the nation's schools of medicine, dentistry, public health, osteopathy, nursing and others, universities, and other private research institutions.

---

* Substance of an address given before the International Symposium on Microchemical Techniques, at the Pennsylvania State University, University Park, Pennsylvania, on August 16.

During the Fiscal Year 1961 (which ended June 30, 1961) the intramural programmes totalled approximately 85 million dollars.

Principal among the numerous buildings devoted to the intramural programmes is the Clinical Center, a 516-bed research hospital with 1,100 laboratory units and 1,260,400 sq. ft. of space. It employs more than 1,500 persons.

During the same year, the extramural programmes totalled approximately 475 million dollars (the latter having grown from 850,000 dollars in 1946). In this connexion, 13,500 research grants, 3,618 training grants and 4,205 fellowships in the United States and abroad were awarded.

Perhaps it seems an over-simplification, but it is accurate, to say that the National Institutes of Health are supporting and/or carrying out research in every biomedical science and nearly every disease known to man. At one extreme, they are supporting work on the very origins of life—how the amino-acids came together to form a primitive proteinoid, and developmental biology, embryology, genetics, and diseases of childhood. At the other extreme, the biological processes of ageing and the rehabilitation and home-environmental problems of older people are being examined. Literally, we are concerned with life from before conception to death, and all the stresses which assail man in his existence—organic disease, and psychological and environmental stresses.

Until 30–40 years ago the major causes of serious illness and death were the infectious diseases. These diseases received most of the attention of medical research because they were the major killers.

Then penicillin became available, followed by many other antibiotics, and while these certainly did not end the problems of infectious diseases they drastically changed the overall picture of medical research.

We cannot claim final victory over pathogenic micro-organisms because, obviously, they can mutate (and there exists, for example, penicillin-resistant *Staphylococcus*), thus, we are left with unsolved problems.

On the other hand, it is the chronic diseases, such as heart disease, cancer and others, which to-day have become the major killers. In the United States alone, different forms of cancer kill about 260,000 persons every year, and heart diseases account for nearly 900,000 deaths every year. So it is these diseases which are now attracting major attention, along with neurological disorders, arthritis and the entire spectrum of metabolic diseases, mental health, allergy, and dental disorders, and there we have the titles of the seven Institutes at Bethesda: Allergy and Infectious Diseases, Arthritis and Metabolic Diseases, Cancer, Dental Research, Heart, Mental Health, and Neurological Diseases and Blindness.

In terms of scope, the National Institutes have recognized the necessity of becoming concerned with the entire scheme of man's existence—the whole organism of man in relation to disease and his total environment, including both the psychological and physical.

As one example of the scope of research, the Institutes are providing new and increased opportunities for such para-medical scientists as anthropologists, biometricians and epidemiologists to clarify the relationships between cultural stresses and diseases, for example, as in the relationship between the high intake of fat in certain cultures and the incidence of atherosclerosis.

If, for another example, we consider the field of psychiatry, we find that it, too, is expanding beyond the limits of the office couch into environmental studies, on one hand, and yet also much deeper into the part that biochemistry may play in the origins of, as well as therapy for, mental and/or emotional disorders.

As to the depth of our research penetrations, I would like to quote Dr. James A. Shannon, director of the National Institutes of Health[1]: "Although until recently we were limited in our examination of the economy of the body as a whole—its net energy balance, the net exchange of foodstuffs, and the endocrine factors that were effective in producing changes in these—we are now able to isolate for study important specific systems within cells and to define with precision many of the discrete steps which characterize their activity. We can describe the components of these systems, quantitate the kinetics of the interactions involved, study the effect of superimposed variables upon these reactions, the products of which may be retained or released. By other techniques we can describe the importance of many of these systems to the cell, to the organ, to the organ systems and, in fact, to the body as a whole".

The pattern of much of the biomedical research in the world to-day is the pursuit of a much larger, broader, deeper, more integrated body of knowledge about basic human biology. The National Institutes have accepted this charge, and the acceptance of this new challenge has found wide expression in all the Institutes' programmes, particularly that of the Division of General Medical Sciences.

In effect, the Division of General Medical Sciences is the eighth Institute at the National Institutes of Health, because it functions as an Institute in all respects except that there is no intramural programme. The programmes are devoted entirely to grants to the medical schools, universities, research hospitals and other private research institutions. In the research training programme, which also is oriented toward the basic biomedical sciences, funds are provided to the medical schools and other institutions to aid in the training of new investigators. In the research fellowship programme, awards are made to individuals, at the predoctoral and post-doctoral levels, to aid the general research training development of scientists.

Until recently, nearly all the Division's research grants have been on an individual project basis, and the grants of this type in the Division of General Medical Sciences alone total approximately 2,000. One modification of this procedure came in the establishment of the General Clinical Research Center Program which provides funds to medical schools and research hospitals. The purpose of these grants is to broaden and intensify clinical research, particularly in the sense of achieving careful quantitative measurements of disease. The funds go for the establishment of discrete facilities or centres for the location of beds and laboratories. A variety of different research projects can be carried on in these centres. Another modification of the individual

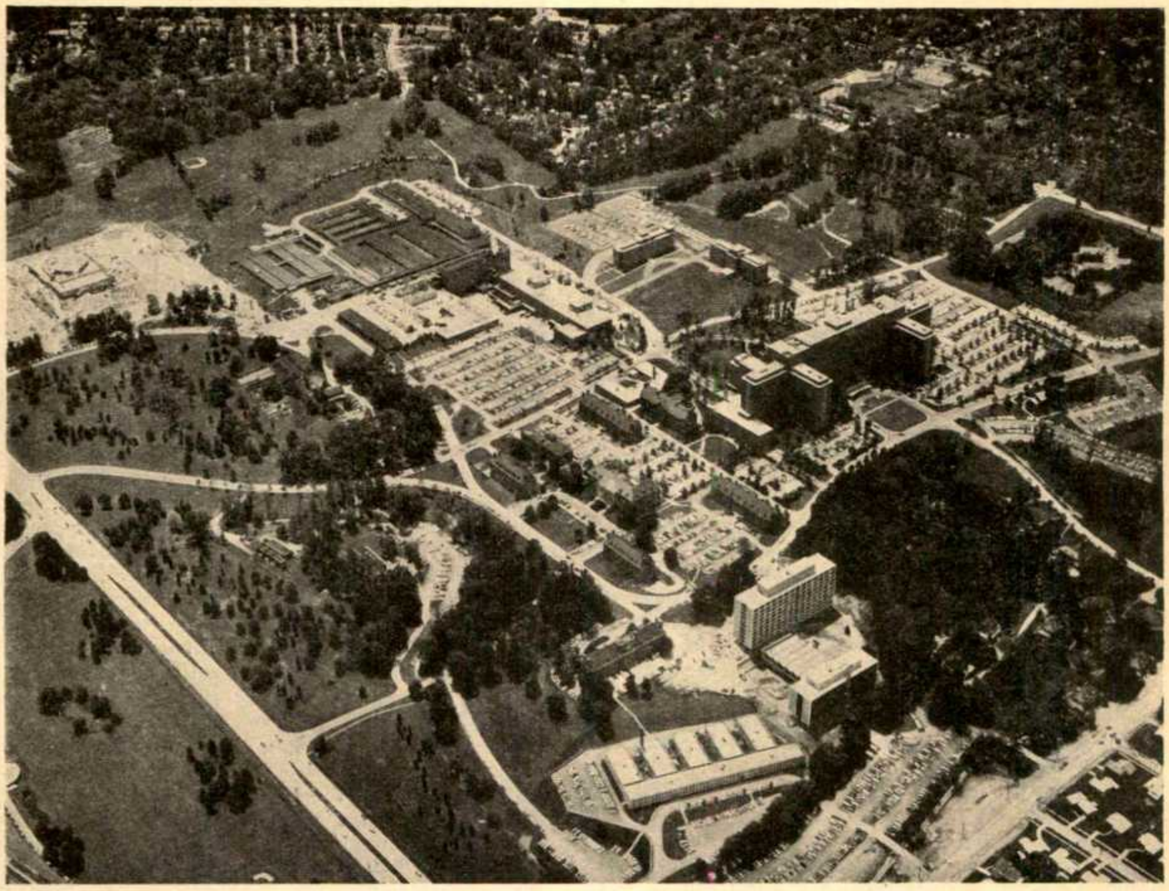

Fig. 1. The National Institutes of Health, Bethesda, Maryland, U.S.A.

project procedure is the new General Research Support Grants Program, which was recently initiated. This will provide the schools of medicine, public health, dentistry and osteopathy and other institutions with funds which these institutions may then use for the support of their research programmes. The feature which principally distinguishes this programme from most other National Institutes of Health and Public Health Service programmes is the even greater freedom given the institution in the use of these funds.

The establishment of the Division of General Medical Sciences just three years ago was an expression of the broader and deeper research approach of the National Institutes of Health. The research programmes of the Institutes have always involved basic research; but for the most part these programmes have been oriented to specific diseases. In the mid-1950's, there was recognized a need for more basic research, and basic research training, which was not disease-oriented. The National Institutes began making a number of grants for such purposes, and by 1958 it became apparent that the demand was such that a unit should be established especially for the administration and management of these grants. The reaction of the biomedical-scientific community to this development was such that expenditures for the Division's programmes have more than tripled since it was organized. During the past year, these programmes totalled nearly 85 million dollars. Further recognition of the importance of these programmes has come in a recent proposal by President Kennedy to the Congress that this Division be established as the National Institute of General Medical Sciences.

While the Division's activities are generally not oriented to specific diseases, their justification is the urgent need for basic biological knowledge essential for progress in the conquest of human diseases.

A simple example—but not a simple problem—pertains to research in the biological process of ageing and, more specifically, to recognition of the distinctions between the physiological ageing process and the pathological disease process.

Molecular biology is a field in which the Institutes are very active. One is sure that work in this area eventually will provide much additional information on such problems as rheumatic syndromes, infertility, tuberculosis, virus infections, cancer, hypertension, schizophrenia and alcoholism, because all these conditions involve disordered chemical processes of cellular metabolism.

In recent years, of course, modern biochemistry has come into its own, with its progress and expansion being such that it has fathered a number of subdisciplines and has become integrated into nearly all phases of medical research.

In the field of developmental biology, the Institutes are seeking to be as broad and deep as in biochemistry. Research is being supported in all phases and aspects of structure and function related to genetics and reproduction. These would include the germ cells and fertilization, the placenta, the fœtal fluids, the embryo and fœtus, teratology, parturition and lactation, and special problems of gestation.

The field of genetics, of course, continues to grow at a tremendous rate, but we do not yet know its full significance in human biology and in disease. Dr. Jack Davies, of Washington University, St. Louis, has said: "How the genetic and environmental factors act and interact during development (of the fertilized egg) is perhaps the fundamental problem of biology"[2]. The implications with regard to congenital malformations and other hereditary diseases are, of course, obvious.

The work on the deoxyribonucleic and ribonucleic acids is beginning to provide a new concept of man and of disease. Among the great amounts of research that the Institutes are supporting in this field is that by some Israeli scientists on the role of the ribonucleoprotein complex of the cell in the synthesis of antibodies.

Modern geneticists are beginning to predict that man some day may be able to control his own biological destiny by influencing the genetic factors. This is one of the reasons for emphasis on medical and human genetics, cytogenetics, viral and bacterial genetics, biochemical genetics and genetic ultra-structure.

There are many other basic fields in which the National Institutes are also active. Examples are: public health and nursing; biomedical instrumentation; research surgery; anæsthesiology; bio-organic and biopolymer chemistry; biomathematics; and biophysics.

As the American interest in biomedical research and improved health is integral to all elements of the U.S. Government, so also is it an interest to be shared with the other countries of the world, for mutual benefit.

Such an effort has two goals: the first is the interchange of newly developed fundamental knowledge among the scientists of the world; and the second is the equally substantive advantage in biomedical research of learning more about the incidence and variable characteristics of specific diseases and also general biological phenomena in different parts of the world, as related to variations in climate, altitude, food, culture and other factors.

Just a year ago, the President of the United States signed the International Health Research Act of 1960. In general, the Act provides for support of research activities in foreign countries, research training and fellowships, the making of grants and loans of equipment, the support of international health research meetings, and the exchange of research scientists.

For the Fiscal Year 1961, just passed, a sum of 5 million dollars was designated for the development of activities under the Surgeon General's authorities provided by this Act. Approximately a half this amount was allocated for the development of a series of international centres for medical research and training, based in United States universities with overseas extensions in the form of research laboratory training facilities.

Each of the centres consists of, first, a professional, university-based organizational entity which provides a stable, continuing framework in which programmes of medical research, research planning and research training may be conducted in the United States, and which is associated with the second part, a research and training establishment abroad where these activities may be pursued under environmental, ethnic, and medical conditions which do not prevail in the United States.

The remaining 2·6 million dollars are to be utilized by the several Institutes and the Division of General Medical Sciences for the support of research projects involving foreign investigators and institutions, and directed toward research and research training objectives of key significance to these projects.

The National Institutes of Health recently established an Office of International Research, within the office of the Director of the Institutes. This new Office has the responsibility of advising the Director and the Office of the Surgeon General on the international aspects of medical research and research training. It also assists the Institutes and the Division of General Medical Sciences in the further development of international projects, and provides a mechanism by which the National Institutes of Health can work with international organizations, foreign institutions and scientists on a planned, predictable, long-range basis.

In years past, there has been talk about the need for an international language. We already have an 'international language' in the field of biomedical research. It is a subject which transcends geographical boundaries and defies language barriers. It is the goal of the National Institutes of Health and the whole American Government to improve and expand this 'language' to bring all the countries of the world closer together in the common cause of good health for all men.

RUTHERFORD JUBILEE INTERNATIONAL CONFERENCE ON NUCLEAR PHYSICS

THE fiftieth anniversary of the publication of Rutherford's 1911 paper announcing the discovery of the atomic nucleus was celebrated by an international conference during September 4–8 at Manchester on what is nowadays called 'low-energy' nuclear physics. The conference was attended by more than four hundred people; its wide support will undoubtedly make it the major international meeting in its field in 1961.

As is usual with these almost annual events, progress during the past year was summarized; but on this occasion half a day was set aside from the discussion of present problems for a commemorative session on Rutherford's discovery. There were talks on their reminiscences by Sir Ernest Marsden, Sir Charles Darwin, Prof. E. N. da C. Andrade, and Prof. Niels Bohr, all of whom had worked with Rutherford at Manchester. Sir James Chadwick was present on the platform but did not speak. In these talks there came to life a period which to many of those present had been a legend they had read about only in text-books. Here was the tale of

Marsden whom Rutherford told to look for the reflexion of α-particles from solids, something which neither Rutherford nor Marsden expected to happen, but Marsden knew that if the effect existed and he missed it, that would be the end of him Then there was Darwin's story of collaboration with Moseley, whose methods of non-stop work made him not only an expert on X-rays but also on where to get a meal in Manchester at three o'clock in the morning Niels Bohr closed the session with a few brief remarks in which he laid special stress on the central importance of Rutherford's discovery in providing a testing ground for the theorists during the development of the quantum theory beyond the point to which Planck and Einstein had taken it.

The remainder of the conference was conducted in an atmosphere moulded by the portrait of Rutherford which looked down on the participants over coffee, and the presence of an exhibition of much of his apparatus The complete proceedings will be published soon, so that here there is no need to mention more than a few topics the selection of which from the wealth of material presented is to a large extent a matter of personal taste

There was steady progress to report on several fronts. The question of the fundamental origin of the interaction between nucleons has become clearer in recent years with the accumulation of evidence that the component of longest range is what would be expected from the exchange of single π-mesons. Further evidence of this effect has now come from an extensive analysis of the scattering of nucleons by nucleons in states of high relative orbital angular momentum where the centrifugal barrier makes the effects of longest range predominate, as it should, the strength of the coupling between nucleons and mesons required turns out to be the same in neutron–proton and proton–proton scattering, and agrees with that needed to account for the scattering of π-mesons by nucleons The dependence of the long-range interaction on the spins of the nucleons also agrees with the theory A new development in the field of nucleon–nucleon interactions is a direct measurement of the strength of the interaction of two free neutrons by means of the reaction $D(n,p)2n$ at low energies which is strongly influenced by the interaction of the two outgoing neutrons, the first result is not far off the value to be expected from p–p scattering on the grounds of charge-symmetry Another problem which is at last showing signs of being cleared up is the origin of the spin-orbit coupling between two nucleons which had been introduced phenomenologically to account for scattering at high energies, this is probably connected with the existence of a short-lived quasi-bound state of three π-mesons of angular momentum unity—the '3π-resonance'—the discovery of which was announced at the conference The spin-orbit coupling would arise analogously to that which acts between two electrons due to the electromagnetic field

Some fundamental points in connexion with the shell model are still being elucidated, in particular the origin of the strong spin-orbit coupling seen by each particle in a nucleus, and the existence and properties of the low-lying single particle states which are not normally involved in low-energy reactions The origin of the spin-orbit coupling probably also lies in the newly discovered 3π-resonance, through a mechanism analogous to the production of the spin-orbit coupling in atoms The low-lying single particle states are now beginning to show up in $(p,2p)$ experiments, the incident protons have an energy of about 150 MeV and are able to knock a proton out of the target, the spectrum of the summed energies of the two emerging protons showing clearly defined peaks corresponding to the binding energy of the ejected proton The measurements on isolated nuclei which were previously available have now been extended until the binding energy of the lowest-lying level—the $1s$—has been traced for elements up to atomic number 20 The same experiments can also give the original momentum distribution of the struck nucleon from the angular correlation of the emerging protons.

There was much discussion of two aspects of nuclei which go qualitatively beyond what can be described by the simple shell model built up from the picture of individual nucleons moving in a static potential well These were the structure of the nuclear surface, where there may be important clustering effects, and collective motions in which many particles partake coherently in such a way as to generate an oscillating or rotating potential well On the structure of the nuclear surface, new evidence produced during the previous year supports the view that the surface is probably more 'lumpy' than a simple shell model would lead one to expect This evidence comes partly from new estimates of the probabilities of α-particle emission in some heavy nuclei on the basis of shell model wave-functions which give values smaller by about a factor 10^3 than the experimental ones There is also new information on the absorption of K^- mesons at the periphery of a nucleus from bound Bohr orbits, where the existence of correlations between the nucleons can be detected by the possibility of the production of very energetic hyperons in absorption mechanisms such as $K^- + 2$ nucleons $\rightarrow$ hyperon + nucleon, in addition to the less-energetic hyperons which are emitted in the process K^- + nucleon $\rightarrow$ π-meson + hyperon, which is the only one to occur for free nucleons The situation is not clear because it appears that in the light nuclei, in contrast to the heavy ones, it is possible to account for the emission and absorption of compound particles with a simple shell model without recourse to any additional clustering

The field of collective oscillations is still developing under the new impetus it received from the discovery of the importance of particle-hole pairs and of pairing correlations at the top of the Fermi sea So far most of the emphasis has been on quadrupole and octupole shape oscillations, and on the giant dipole resonance in which the protons oscillate against the neutrons. The theory gives the frequencies of collective oscillations in terms of the energies of the single particle excitations which contribute, and the probabilities of occupation of the single particle-levels involved Measurements of these properties by means of stripping reactions now exist in a limited number of nuclei, and the collective frequencies calculated from them are found to vary from nucleus to nucleus in agreement with the measured values However, in the prediction of electromagnetic transition probabilities the theory is still only in semi-quantitative agreement with experiment

A welcome contribution was a talk under the title of "Rutherford and Nuclear Cosmochronology", by W A. Fowler, who discussed the present estimates of the ages of the Earth, the solar system and the Galaxy, making use of the known abundances of the elements and of calculations of these abundances from the synthesis of the elements in stars and supernovæ It turns out that where Rutherford in 1929 gave the age of the solar system as 3 4 × 10^9 years, the best present estimate is still as close as 4 5 × 10^9 years

The success of the conference amply repaid the members of the organizing committee for their labours If they have one regret, it is that the limited space available made it necessary to refuse a place to many whom they would have liked to have seen If some active and distinguished research workers feel disappointed at our inability to invite them, may we ask them to bear in mind that the places which were due to them probably went to representatives of isolated institutes for whom these conferences are the only real contact with the main stream of research in nuclear physics A HERZENBERG

ENDOCRINOLOGY AND EVOLUTION

DURING the recent meeting at Norwich of the British Association for the Advancement of Science a symposium on "Endocrinology and Evolution" was held under the auspices of Section D (Zoology), with Prof C M. Yonge in the chair

In the opening paper, Prof E J W Barrington pointed out that while far too little is known about the ways in which hormones exert their effects, it seems evident that there must be a closely adaptive relationship between the active hormonal molecules and their target cells This raises the questions when, and in what circumstances, these relationships were first established, questions which are important because the answers to them can scarcely fail to enlarge our understanding of the primary functions of the hormones concerned He developed this theme with particular reference to the thyroid gland, an organ which shows a remarkable uniformity of biochemical organization through the vertebrates, from the cyclostomes to the mammals Its characteristic iodinated tyrosines and thyronines are known to be produced in the endostyle of the ammocœte larva of the lamprey, before this organ has been transformed at metamorphosis into the definitive thyroid gland It would appear, therefore, that any search for clues to the mode of origin of the gland must take us outside the vertebrates altogether

Here we cannot fail to be struck by the fact that iodine has long been known to be present, and often in great abundance, in many marine invertebrates Our knowledge of this phenomenon has been greatly extended in recent years by the use of radioactive iodine, and by employing the techniques of autoradiography and paper chromatography These have shown that the organically bound iodine of marine animals is not strictly of a thyroidal character, for instead of being bound within thyroglobulin molecules it is commonly associated with the scleroproteins of the skeletal tissues These have been closely studied in the Anthozoa and sponges, and it has been found that their iodine content may be surprisingly high, as much as 10 per cent as compared with the 1 per cent of thyroglobulin It seems likely that the amount of iodine taken up by the scleroprotein molecules depends on their tyrosine content, and that it is mainly bound as monoiodotyrosine and diiodotyrosine, although trace amounts of thyroxine and triiodothyronine have been reported present in the horny skeleton of gorgonids

The organic binding of iodine in invertebrates thus appears to be a chance consequence of the molecular constitution of their skeletal tissues, and this raises the question whether there is any evolutionary relationship between it and the highly specialized iodination sequences of the thyroid gland We cannot be sure of the answer to this, but consideration of the results of recent work on the protochordates, which are known to be closely related to the vertebrate line of ancestry, suggests some interesting reflexions Autoradiography has demonstrated the occurrence of iodine binding in certain clearly defined cells of the endostyles of ascidians and amphioxus, and chromatography has shown that iodinated tyrosines and thyronines are present in these animals There is some evidence that these substances may be associated with the specialized outer layer of the tunic of ascidians, as well as with the endostyle, so that these particular animals may eventually be found to show random iodination side by side with the endostylar process which foreshadows the eventual emergence of a true thyroid gland

It is attractive to speculate that iodinated products arising thus by chance in early chordates might have become metabolically available for the animals, by ingestion or by transport in the blood stream, and that increasing dependence on these would have led to the evolution of a more efficient biosynthetic mechanism in the endostyle At the present time this is no more than a thought to guide further investigation, but we certainly cannot dismiss the possibility that the thyroid hormones evolved as a result of animals incorporating into their biochemical organization substances which were initially presented to them as random biological products

Any discussion of the evolution of hormones needs to take account of the fact that they do not act in isolation, but as components of highly integrated systems of mutually interrelated glands Prof J M Dodd was to have discussed this aspect with particular reference to the work of himself and his colleagues on the relationship between the pituitary and the thyroid, but he was unable to attend, so his place was taken by Dr K M Ferguson, who began by remarking that although the controlling influence of the pituitary over the thyroid, mediated by its thyroid-stimulating hormone, is well known in mammals and amphibians, it is not always so easy to demonstrate it in the other vertebrate groups Nevertheless, there is ample evidence of a qualitative nature to demonstrate that this so-called pituitary–thyroid axis is probably common to the entire vertebrate series For example, although neither removal of the pituitary nor administration of mammalian thyroid-stimulating hormone produces significant histological changes in the thyroids of adult elasmobranchs, Dent and Dodd have shown that a distinct thyroid–pituitary interrelationship exists in the immature, newly hatched dogfish, *Scyliorhinus caniculus*, and that its thyroid-stimulating hormone is probably located in the ventral lobe of the pituitary

Quantitative evidence is scanty, but by using the mouse assay of McKenzie it has been possible to demonstrate thyroid-stimulating activity in pituitary extracts from animals ranging over the entire vertebrate series, although at considerably lower concentrations than are found in mammals Certain features of these results, however, present difficulties of interpretation. For example, a large part of the activity is heat-stable, while mammalian thyroid-stimulating hormone is markedly heat-labile Moreover, measurable activity is obtained from the neural lobe, even in the mammal, although there is every reason for regarding thyroid-stimulating hormone as a product of the adenohypophysis The significance of these facts is bound to remain obscure until we are better informed of the chemical nature of thyroid-stimulating hormone, but in the meantime it is necessary to remember that glandular extracts may contain a large number of contaminants, hormonal and otherwise, which are likely to interfere with responses, and which cannot be adequately controlled by injections of indifferent tissues such as brain or muscle It is possible, too, that foreign pituitary material may set up interfering stress responses, while it is known that the relative thyroid-stimulating potency of extracts from different species varies according to the choice of the assay animal

These considerations combine to make it impossible to decide whether the apparently low concentrations of the hormone in extracts of pituitaries of the lower vertebrates reflect quantitative or qualitative differences It may be, however, that the thyroid-stimulating hormone molecule has been subjected to biochemical evolution, but has yet retained sufficient community of chemical structure throughout the vertebrates to allow pituitary extracts from a wide range of donors to stimulate the thyroids of a wide range of recipients

Further aspects of endocrine evolution were brought to light in Dr J G Phillips's discussion of the adrenal gland There is much variation in the gross appearance of this organ, and in the degree of association of its two components, the chromaffin and the adrenocortical tissue, but these variations, characteristic of each of the main vertebrate groups, mask a remarkable constancy in the properties of its secretory cells This is well illustrated by the steroid hormones of the adrenocortical tissue, which appear to be chemically identical throughout the vertebrate series, and which are involved in homeostatic mechanisms contributing in one way or another to ensure a constancy of the internal medium Nevertheless, this fundamental uniformity has not prevented the establishment of a wide degree of functional adaptive radiation In the sphere of water and salt metabolism, for example, these hormones influence tissues such as the nephron, the gills of fish, and the skin and bladder of frogs, all of which share a common capacity for the transcellular conduction of electrolytes and water, and which react to adrenocortical hormones in a manner determined by the nature of the environmental hazards to which the particular species is exposed Thus, marine fish are faced with the problem of retaining water and excreting excess salts, while the converse situation confronts freshwater species, and these hormones, although not the only factors involved, contribute to the necessary physiological adaptations by their action on the kidneys and the gills In sea-water they promote the excretion of excess electrolytes through the gills, and the maximal re-absorption of water in the kidneys, while in fresh water they promote the excretion of large volumes of dilute urine, accompanied by salt retention

It is evident that one important factor in the evolution of endocrine systems is the possibility of change in the character of the target organs, and Dr Phillips illustrated this by reference to recent work on the remarkable ability of marine birds to survive for long periods the ingestion of fluids which have an ionic concentration many times higher than that of their body fluids This ability depends on the nasal glands situated above the eyes Following the ingestion of sea-water, these glands are activated, and, as a result of their remarkable concentrating ability, the bird excretes the excess salt through the nasal gland without commensurate loss of water The action of the adrenocortical hormones is one of the factors involved in this response, and there is evidence that, with the hormones of the neural lobe of the pituitary, they arrest the excretion of the excess salt through the kidney; this is then followed by a shift to the physiologically more economical method of excretion through the nasal glands There is good evidence that the latter are also dependent on the nervous system, but at present it is not possible to judge the relative importance of the two forms of control It is clear, however, that the action of the adrenocortical hormones on the nasal glands is closely analogous with their action on the gills of marine fish, for in both cases they serve to promote the excretion from the body of excess salt without undue loss of water.

The final paper was given by Dr D B. Carlisle, who reviewed some problems of crustacean endocrinology, and this was followed by a lively discussion which ranged over such diverse problems as sex-reversal in molluscs, the function of indole derivatives in crustaceans, the influence of ciliary feeding in the evolution of the thyroid gland, and the possible role of adrenocortical tissue in the metamorphosis of lampreys. The session as a whole must have done much to reassure those who fear that endocrinology, with its para-medical background and its esoteric terminology, is too specialized for comprehension by the general biologist, and it amply demonstrated how widespread are the biological problems which are being illuminated by present developments in the comparative study of endocrine mechanisms

E J W BARRINGTON

OBITUARIES

Prof. H. P. Robertson

PROF. H P ROBERTSON, who contributed to the theories of relativity and cosmology, and was a member of many Government scientific boards in the United States, died on August 26 as a result of injuries sustained in a motor-car accident His death takes from many people throughout the world a sensitive, gay and ever-helpful friend as well as an experienced and wise counsellor

He was born in Hoquiam, Washington, on January 27, 1903, and received his bachelor's and master's degrees in 1922 and 1923, respectively, from the University of Washington, where he was introduced to the Einstein theory of relativity by E T. Bell

He obtained the Ph.D. degree from the California Institute of Technology in 1925 and then spent two years in Germany as a National Research Fellow at Gottingen and Munich. He joined the Mathematics Department of the California Institute of Technology as an assistant professor of mathematics for the period 1927–29.

During 1929–47 he was at Princeton University, occupying successively the posts of assistant professor, associate professor and professor of mathematical physics. In 1947 he returned to the California Institute of Technology as professor of mathematical physics, a post he held until his death.

Although Robertson devoted most of his scientific efforts to the general theory of relativity and to its application to cosmological problems, he was interested in the foundation of physical theories and the application of various branches of abstract mathematics to physical problems. His excellent translation of Herman Weyl's *The Theory of Groups and Quantum Mechanics*, which he completed in 1931, demonstrates his profound knowledge of the theory of groups, quantum mechanics and the relationship existing between these two subjects.

He was a master in applying the theory of groups of motion of Riemannian spaces to problems in relativity. His 1933 paper entitled "Relativistic Cosmology", which appeared in the *Reviews of Modern Physics*, illustrates his use of the technique. In this classic paper he summarizes his own basic work and that of others on the consequences of the symmetry assumptions made in relativistic cosmology and relates these to the astronomical observations. He afterwards studied the implications of the symmetry assumptions alone, divorcing these from the Einstein field equations. The latter work was stimulated by the lively controversy over kinematical relativity, in which he and E. A. Milne engaged, and appeared in three papers and in the *Astrophysical Journal* (1935, 1936) entitled "Kinematics and World Structure".

Robertson's contributions to relativity should not be measured only by his own papers. He engaged in extensive discussions with, and participated in the work of, others. His aid is acknowledged by many authors; in particular, he played an important part in the work of Einstein, Infeld and Hoffmann on the equations of motion of singularities in the gravitational fields and published his solution of the equations for two bodies with comparable masses obtained by these authors.

In 1939 Robertson responded to a call from his friend and mentor, R. C. Tolman, and began his work on scientific problems important to United States military agencies. He stopped his intensive work in relativity, which was just coming to fruition, and answered to the demands made on him with characteristic vigour. He quickly produced a scholarly review of work in terminal ballistics and made contributions to this field. He took an active part in organizing the group that became Division II of the National Defense Research Committee and in directing the early work of this group.

He served with the National Defense Research Committee from 1940 until 1943 and as scientific liaison officer, London Mission, Office of Scientific Research and Development, during 1943–46. From 1944 until 1947 he was an expert consultant to the Office of the Secretary of War. In 1945 he was chief of the Scientific Intelligence Advisory Section of Supreme Headquarters, Allied Expeditionary Force in France. For his war service he received the United States Medal of Merit.

In 1950 he was called back to Washington and served for two years as deputy director and research director of the Weapons Systems Evaluation Group of the Department of Defense until 1952. During 1954–56 he was the scientific adviser to General A. M. Gruenther, the then Supreme Allied Commander in Europe. For four years beginning in 1956 he was member at large and chairman of the Defense Science Board. He was also a member of the President's Scientific Advisory Committee.

In addition to belonging to a number of scientific societies, Robertson was a member of the U.S. National Academy of Sciences, of which he was foreign secretary from 1958 until his death.

Although Robertson never lost his interest in working in the theory of relativity and in teaching this subject, his many Washington duties to which he gave himself unstintingly made it impossible for him to do more than publish a few papers after the Second World War. In some of these he again reviewed the theoretical and observational state of the theory of cosmology. He was much interested in the possibilities of using satellites for experimental tests of theories of gravitation and took part in organizing, and was chairman of, a conference on this subject in July last at Stanford University.

This review of some of Prof. Robertson's achievements and activities must of necessity omit much that should be said about him. Suffice it to say that he made his mark in science, in service to his country, and in the hearts of the many people from all walks of life who were privileged to know him.

A. H. TAUB

Mr. Lewis Eynon

THE news of the death on October 18 at the home of his son at Stoke Bishop, Bristol, of Lewis Eynon will sadden his friends in many countries. The sugar industry has lost a most experienced analyst, who further had done so much to help the analytical profession. Eynon was born in 1878 at Stoke Newington and was educated at the City of London School. On leaving there he became a student at Finsbury Technical College during 1895–99 under Prof. Meldola. He was then appointed a chemist to the Beetroot Sugar Association. Another Finsbury student, J. H. Lane, was also there with him, and the two became partners in 1910 as consulting chemists. Having acquired the laboratories from the Sugar Association of London, as it had then become, and also the business of the analysis of its sugar samples, they had spare time which they used for research on sugar, chiefly on improvement of methods of sugar analysis. Their long search for a sensitive internal indicator for use with Fehling's solution for testing reducing sugars eventually led them to methylene blue. The result was the Land and Eynon method which has become well known throughout the sugar world. It has eventually been accepted as an official method by many countries and also by the International Commission.

Eynon obtained many qualifications and held many important offices among the various professional bodies to which he belonged. In 1900 he gained the associateship of the Royal Institute of Chemistry and was elected to the fellowship in 1903. A year later he graduated B.Sc. at the University of London with honours in chemistry. For many of the years between

1920 and 1949 he served on the Council of the Royal Institute of Chemistry, and during 1930 he was a vice-president. An early member of the Society of Public Analysts (later the Society for Analytical Chemistry) he served on the Council, was honorary secretary during 1936–47 and president during 1947–49 He attended the meeting of the eighth session of the International Commission for Uniform Methods of Sugar Analysis, held in 1932 at Amsterdam, and was elected honorary secretary, in which position he remained until the end of the ninth session in London in 1936 He was also chairman of the Publication Committee, responsible for the production of the *Proceedings* for the eighth, ninth, and tenth sessions In 1932 he became honorary secretary of the newly formed British National Committee of the Commission, which position he relinquished in 1948 to become chairman This post he held until 1954 The same year in Paris at the eleventh session of the Commission he was unanimously elected life honorary vice-president "in grateful recognition of his extensive and valuable services to the work of the Commission and for his distinguished contributions to the literature and practice of sugar analysis"

At the end of more than sixty years of a very busy life, he was still the same gentle-mannered man, a very kindly character, unassuming and loved by all who knew him, his many friends could count on the encouragement and help that was always forthcoming.

H. C S de Whalley

NEWS and VIEWS

Nobel Prize for Physics:

Prof Robert Hofstadter

Prof Robert Hofstadter, who shares the Nobel Prize for Physics with Prof R L Mossbauer, was born on February 5, 1915, he received the bachelor of science degree from the City College of New York in 1935, and his Ph D from Princeton in 1930 He then taught and carried out research at Princeton, Pennsylvania, and the City College of New York until the war years, during which he worked at the National Bureau of Standards and the Norden Laboratory Corporation. For four years after the War he was assistant professor at Princeton, but in 1950 he went to Stanford as associate professor, becoming professor in 1954, and eventually head of the department Prof Hofstadter is best known for his use of high-energy (roughly 1 BeV) electron beams to probe the structure of nucleons A knowledge of the form of the meson clouds surrounding the proton and neutron has been at the foundation of important recent developments in quantum field theory It is not possible to give an adequate idea of this work in a short space, but the success of his work is perhaps best illustrated by the discussion it provoked in the United States of the feasibility of constructing an electron accelerator of still higher energy

Prof. R. L. Mossbauer

The early recognition of the importance of Prof R L Mossbauer's work by a share of the Nobel Prize for Physics will give great satisfaction to all physicists The recognition might have been even earlier if Prof Mossbauer's work, carried out at the Max Planck-Institut at Heidelberg in 1957, had not passed strangely unnoticed for nearly two years The discovery of what is now called the 'Mossbauer effect' is concerned with the spectrum of the γ-rays which are emitted by certain excited nuclei It has been known for many years that the nuclear levels in many cases are extremely sharp, but considering the problems of nuclear recoil and lattice vibrations which introduce Doppler shifts, physicists had resigned themselves to the conclusion that the very narrow γ-ray lines which exist in principle would remain for ever inaccessible Mössbauer's achievement lies in recognizing that in certain specific cases, appreciable fractions of the γ-rays may be emitted undisturbed by recoil or lattice vibrations The imaginative achievement is the more remarkable when one considers that the theory underlying the effect has been known for twenty years, but the relevant inferences had not been drawn The first spate of new results obtained by making use of the Mossbauer effect in experiments to test the predictions of relativity theory, to investigate the properties of the solid state, the nature of magnetism and the properties of some nuclear excited states has now subsided, but there can be no doubt that the application of the discovery will continue to be a subtle tool in all branches of science

Nobel Prize for Chemistry :

Prof M. Calvin, For.Mem R.S

Prof M Calvin, who has been awarded the Nobel Prize for Chemistry for 1961, took his doctorate at the University of Minnesota and afterwards spent two years at the University of Manchester with the aid of a Rockefeller Grant In 1937 Prof. Calvin joined the staff of the University of California. Discovery of the long-lived isotope carbon-14 during the War (prior to which only the short-life isotope carbon-11 had been available) provided an opportunity for a comprehensive study of the intermediates of photosynthesis which was immediately realized by Prof Calvin Success came when the isotope technique was combined with the then recently discovered paper chromatographic method of analysis In work with A A Benson and later others, the first product of the photosynthetic fixation of carbon dioxide was shown to be phosphoglyceric acid and for the first time the importance of the pentose and heptulose phosphates in photosynthesis was realized Calvin postulated a sequence of reactions constituting the 'photosynthetic cycle' in which these compounds formed a synthetic cycle for the incorporation of carbon dioxide. About the same time essentially the same reactions were shown to play an important part in the respiratory process (the pentose phosphate shunt) not only of plants but also of animals The interests of Prof Calvin's group have now moved towards the investigation of the basic mechanism by which light energy is converted into chemical energy in the chloroplast of the green plant Attempts have been made to devise model systems in which light energy can be converted to chemical energy with high efficiency, thus necessitating an extension of the earlier studies of the photochemistry of dyes Prof Calvin was elected a foreign member of the Royal Society in 1959

Nobel Prize for Physiology : Dr. Georg von Békésy
